Pasteur.

By Stephen Paget.

Of late years it has become the fashion to limit the name of preventive medicine to the immunisation of ourselves or of animals against infection. With the one exception of vaccination against smallpox, all methods of immunisation are founded on Pasteur's work. The contrast is remarkable between Jenner's discovery and Pasteur's many discoveries. Jenner, ages back, made a great discovery: but there he stopped. Pasteur not only made discoveries, he made discoverers. We are so accustomed nowadays to the new learning which he brought into the world that we are in danger of forgetting the original wonder of it: the power to identify, isolate, cultivate, and handle, outside the living body, this or that disease to hold in a test-tube the actual cause, the thing itself, the very stuff of disease, growing under our eyes. That is the tragedy of Semmelweiss: he worked out the truth about puerperal fever, but he could not demonstrate the germs of it, therefore he was contradicted, bullied, hounded down, driven mad, and died insane in 1865. Pasteur, in 1878, in a discussion at the Académie de Médecine on puerperal fever, when one of the speakers railed at Streptococcus as a non-reality, forthwith drew Streptococcus on the blackboard, saying, "Tenez, voici sa figure."

Fig. 1.—Pasteur, 1822–1895.

After all, it is impossible, in Pasteur's work and its influences, to separate preventive medicine from curative medicine. Long before Pasteur died every country was at work on his lines. We can take some dates in his life: but he was always living in the work of lesser men whom he inspired. The dates in his life are as follows. In 1842, fortified by the virtues of home-love, and by the courage of youth, he went to Paris: entered the École Normale in 1843, worked under Dumas and Biot at chemistry, and at chemistry only: and in 1848 he solved the problem of the different forms of tartaric acid. For this reason he has been called the founder of stereo-chemistry. His pursuit of the tartrates led him straight to the practical study of the processes of brewing, distilling, vinegar-making, and wine-making. By this work on fermentation, Huxley said of him that he saved France more than enough to pay the indemnity of the Franco-German War. In 1857 came his paper at the Lille Scientific Society on *Bacterium lactis*: he had isolated this ferment, had experimented with it, and this "inoculation" of milk with a culture of germs was the beginning of all bacteriology.

From 1865 to 1870, without giving up his work on ferments, Pasteur set himself, at Alais, to investigate the silkworm disease, which was wrecking the silk-industry of France and other countries. He found not one disease but two—*pébrine* and *flacherie*. The story of his final triumph, after infinite difficulties, in this investigation is marvellous: it is told in his "Études sur les maladies des vers à soie." He used to commend this book to students to guide them in the principles of their work.

Meanwhile, in Paris, Pasteur was advancing from his knowledge of the putrefying of milk with *Bacterium lactis* to the general study of putrefaction as a state of fermentation caused by the living dust in the air. Liebig had thought of putrefaction as a chemical degeneration: Pasteur thought of it as a vital process. It was more than a result of death: it was the act of life. By 1859, the year of publication of "The Origin of Species," he was in the thick of the fight over the origin of life. He in France, and Tyndall in England, proclaimed and proved the truth of "the germ theory": that was our phrase for Pasteur sixty years ago, because the notion of putrefactive bacteria was new to us. This controversy, in scientific and non-scientific society, lasted long. In April 1864 Pasteur lectured at the Sorbonne to all Paris: he reviewed and demonstrated his work; he answered his critics: "I have excluded from my flasks of organic fluids, and am still excluding from them, the one thing which is past man's making: I have excluded from them the germs which float in the air, I have excluded from them life." Finally, he put in very short words the meaning of it all—"La vie c'est le germe, et le germe c'est la vie."

In 1862 Pasteur had noted the presence of germs in ammoniacal urine, such as occurs with cystitis. In 1863 he had told Napoleon III. that his one ambition was to get to know the causes of putrid and contagious diseases. In 1865, when the cholera was raging in Paris, he and Claude Bernard and Deville made many experiments, in vain, on the air of a cholera-ward. That year also, in Glasgow, Lister, sick to death of the old hospital-diseases, set himself, by the "flood of light" which came to him from Pasteur, to prevent wound-infection by dressing wounds with carbolic acid. He was, of course, hampered by the need of wider knowledge, and by undue fear of the "putrefactive bacteria" in the air. Besides, his first carbolic acid was fallible stuff: he would have done as well, or better, with iodine or spirit. But the point is, that he had got hold of principles that are infallible. He had abandoned the fatal notion that putrefaction was caused by the oxygen of the air. Under this notion he had worked hard, in vain, to prevent wound-infection. "But when Pasteur had shown that putrefaction was a fermentation caused by the growth of microbes, and that these could not arise *de novo* in the decomposable substance, the problem assumed a more hopeful aspect. If the wound could be treated with some substance which, without doing too serious mischief to the human tissues, would kill the microbes already contained in it and prevent the future access of others in the living state, putrefaction might be prevented, however freely the air with its oxygen might enter" (Lister's presidential address to the British Association, 1896). On these principles—with many changes and improvements of the original method of "Listerism"—all that we call antiseptic and aseptic surgery was founded and built.

In the war of 1870–71, the French Army suffered heavily from wound-infection. After 1871, while Lister was practising Pasteurism in Edinburgh, Pasteur was teaching Listerism in the hospitals of Paris, and was defending it against the old school of practitioners. Thus he was one of the founders of modern surgery in France. During this phase of his work he identified Streptococcus alike in boils and in osteomyelitis, and properly said that osteomyelitis is "a boil in a bone."

In 1877 came the beginning of Pasteur's threefold work on anthrax, chicken-cholera, and swine-erysipelas. In this colossal work, between 1877 and 1881, Pasteur discovered and proved the use of standardised vaccines. By keeping pure cultures of chicken-cholera, he could bring down their virulence, slowly and steadily, from day to day. By passing this attenuated virus through a succession of small birds, such as sparrows or canaries, he could restore it, point by point, to its full strength. By keeping at a lowered temperature pure cultures of anthrax, he could hinder their sporing, and bring down their virulence. By passing this attenuated virus through a succession of guinea-pigs, he could restore it, point by point, to its full strength. With such methods of attenuation and intensification, he was able to standardise diseases in flasks: able to make and to store vaccines, exactly graduated by a fixed scale of their strength. As Roux said of it all, "See how far we have come, from the old metaphysical ideas about virulence, to these microbes that we can turn this way and that way—stuff so plastic that a man can work on it, and fashion it as he likes."

Finally, in 1880–85, Pasteur discovered and established the preventive treatment against rabies. He could not isolate and identify the bacteria of the disease: but his work was on the lines of bacteriology. By a long series of experiments, he obtained his *virus fixe*, his standard of the disease, raised by intensification to such a point that the latent period in rabbits after inoculation with virulent spinal cord, lasted only for six or seven days, never more, never less. This *virus fixe* was even stronger than the virus of an ordinary case of rabies. Moreover, it retained its strength through any number of passages from animal to animal. In brief, he standardised rabies, not in flasks but in rabbits: he shortened its latent period to 6-7 days, and fixed it there. Last of all, as with chicken-cholera, so with rabies, he proved that the spinal cords of rabbits infected with his *virus fixe* lost virulence, slowly and steadily, point by point, by mere keeping. Thus he was able to preserve and

stock, in a complete set of cords, the dried virus of rabies, in every shade of strength, from non-virulence up to full virulence. With a course of vaccines made from these cords, beginning at non-virulence, he could immunise his patients—each dose being made safe by the dose of the previous day. He could do this while the disease itself was latent in the scar of the bite, locked-up and inert. He could outwit the natural disease: could take advantage of its latent period, and deprive it of its one and only chance of flaring-up.

Long before 1885, Pasteur's teaching went all over the world. Between 1880 and 1890 came the discoveries of the germs of tubercle, cholera, diphtheria, tetanus, and Malta fever. In 1893, diphtheria antitoxin, and the protective treatment against cholera. In 1894, tetanus antitoxin. In 1896–97, the protective treatments against typhoid and plague. And so on.

Fig. 2.—Pasteur statue at the Sorbonne, Paris.

There is no room here to try to guess how many millions of animal lives have been saved or safeguarded by the protective treatments against anthrax, rinderpest or pleuro-pneumonia: no room to say what has been gained by the mallein test for glanders. Whether we look at the animal creation or at our own, we find everywhere the following-out of the new learning which Pasteur made possible.

The War demonstrated, on a vast scale, the supreme importance of the methods of preventive medicine. They go back, all of them, to that original plan of isolating, cultivating, and finally standardising and grading, the agents of disease: that plan which Pasteur took in hand in 1877.

Happy are those of us who remember the joy of seeing him, hearing him, shaking hands with him. Let alone the wonder of his discoveries, there is the wonder of the beauty of his spiritual gifts. Our admiration of what he did for us cannot hide from us what he was in himself.

Pasteur Aphorisms.

Science has no nationality because knowledge is the patrimony of humanity, the torch which gives light to the world.

* * *

If science has no country, the man of science should have one, and ascribe to it the influence which his works may have in this world.

* * *

The cultivation of science in its highest expression is perhaps even more necessary to the moral condition than to the material prosperity of a nation.

* * *

Science should be the highest personification of nationality because, of all the nations, that one will be foremost which shall be first to progress by the labours of thought and of intelligence.

* * *

Nothing is more agreeable to a man who has made science his career than to increase the number of discoveries, but his cup of joy is full when the result of his observations is put to immediate practical use.

Blessed is he who carries within himself a God, an ideal, and who obeys it; ideal of art, ideal of science, ideal of the gospel virtues, therein lie the springs of great thoughts and great actions; they all reflect the light of the Infinite.

* * *

. . . two contrary laws seem to be wrestling with each other nowadays; one, a law of blood and death, ever imaging new means of destruction and forcing nations to be constantly ready for the battlefield—the other, a law of peace, work and health, ever evolving new means of delivering man from the scourges which beset him.

* * *

. . . the characteristic of erroneous theories is the impossibility of ever foreseeing new facts; whenever such a fact is discovered, those theories have to be grafted with further hypotheses in order to account for them. True theories, on the contrary, are the expression of actual facts and are characterised by being able to predict new facts, a natural consequence of those already known. In a word, the characteristic of a true theory is its fruitfulness.

The Influence of Pasteur on the Development of Bacteriology and the Doctrines of Infection and Immunity.

By Prof. William Bulloch, F.R.S.

To the ancients the cause of plagues and epidemics was a great mystery. Such visitations were regarded either as punishments administered by the Omnipotent to chastise his erring creatures, or as the foul work of a spirit or demon who possessed the powers of evil over men. It was natural that human beings who possessed the ability to ward off the avenging hand or to neutralise the deadly effects of a cacodemon should be esteemed or, indeed, venerated. This was, no doubt, the origin of the Æsculapian worship in ancient times, and was the source of charms, the use of which is not extinct even now. In any case, the cause of disease was believed to be something supernatural, and this was the current doctrine down to the Middle Ages, to be replaced by the view that the cause must be sought in some natural phenomenon rather than a vague supernatural element. Among natural causes of disease were reckoned deleterious changes in the air from miasms emanating from the soil, the effluvia given off from unburied bodies, and such like. Changes in weather were also believed to be effective, and a vague "epidemic constitution"—a "genius epidemicus"—was utilised to explain the repeated appearance of diseases like small-pox, measles, influenza, and scarlet fever. There were also those who believed that telluric influences like earthquakes and floods, or celestial phenomena like the conjunction of planets or eclipses, were responsible for the subsequent outbreaks of epidemic disease.

The idea that disease could be contracted by contact with the sick, although ancient, was never popular and played no important part in the evolution of medical doctrine until the sixteenth century, when its main elements were clearly formulated by Jerome Fracastori (1483–1553) whose work "De Contagione" (1546) constitutes a great landmark in medical history. He clearly differentiated (*a*) contagion by contact, (*b*) contagion by fomites, and (*c*) contagion at a distance. The starting point of his work was the appearance of syphilis, which spread over Europe as a great pandemic at the end of the fifteenth and the beginning of the sixteenth century. In addition to syphilis, small-pox, itch and hydrophobia were clearly recognised as contagious. Contagion, however, did not explain all epidemic diseases. For example, it was clear that, although malaria affected large numbers of people, it was not dangerous for the healthy to come even in remote contact with the sick. Such a disease was believed to be due to some pollution of the air—a miasm, *mal aria*, emanating from marshes. In this way miasmatic were differentiated from contagious diseases, while later, a group of miasmatic-contagious diseases was included. In all cases the miasm, which was not believed to be transmissible directly, was regarded as undergoing some process of maturation in soil, air, or water. At this period, indeed, the influence of the soil and air was regarded as paramount.

By degrees, however, the doctrine of infection clearly emerged and passed through three phases. At first there was the idea that the disease cause was poison was not more nearly defined. The poison was then regarded as the action of a ferment, and the name zymotic still persists. Lastly, in the nineteenth century, the idea became prevalent that the disease cause is not a vague chemical ferment but a living fermenting agent—a *contagium vivum*. The foundation of this great advance is to be sought in the classical observations of Cagniard-Latour (1836) and Theodor Schwann (1837) that yeast—a substance known from time immemorial—is a living organism reproducing itself by a process of budding and producing chemical changes in certain substances termed fermentable. Schwann, in particular, showed that while no yeast cells are to be found in fresh grape juice, their addition to such grape juice is followed by the infallible signs of fermentation and the production of gas. This view, opposed as it was to the prevailing teaching of chemistry, was at first ardently opposed, but in due course was accepted as indicating the truth.

One of the earliest investigators to realise the possibilities of the work of Schwann was Henle the anatomist, and so long ago as 1840 he developed the idea, on theoretical grounds, that microscopic living beings might be the causes of disease; with a remarkable prescience he set forth the principles whereby this might be experimentally proved. Indeed, his suggestions constituted the nucleus on which, forty years later, the whole modern fabric of the etiology of infective diseases was erected. Even so far back as 1835, Agostino Bassi, of Lodi, showed that the muscardine disease of silkworms was due to infection by a fungus. In 1839, Schönlein demonstrated the existence of the Achorion fungus in favus, and Gruby (1843) found the Trichophyton fungus in ringworm.

A new stream of discovery had set in, no longer characterised by vague philosophical speculation but by hard facts established by experiment. To this advancing current Louis Pasteur was the main con-

tributor, and it was chiefly his work that led to the so-called "germ theory" of disease, which by 1876 became an established fact. Pasteur's work on fermentations showed that different chemical products are the outcome of the activities of particular microbes, subsisting in and utilising the fermentible substances. His observations on the alcoholic, lactic, butyric, acetic, urea fermentations, and the abnormal fermentations of wines and beers, are classic and have remained the teaching of to-day. It was by an accident that he was dragged into the conflict on spontaneous generation and heterogenesis, and in a short time and by unsurpassed technique answered the question in the "not proven" sense. Of his principal paper on this subject published in 1862, Tyndall, himself a great experimenter, has said that "clearness, strength, and caution with consummate skill for their minister were rarely more strikingly displayed than in this imperishable essay." Pasteur's works on fermentation and on spontaneous generation acted like a leaven on medical thought, and was the principal cause of the immense advances which, shortly afterwards, took place in our ideas of disease causes. In particular his demonstration of "panspermia," the idea that germs abound everywhere, was the origin of the life work of Lister on the protection of wounds from extraneous contamination and his foundation of antiseptic surgery—the greatest advance ever made in medical art. While Lister throughout his life always referred modestly to his own share in the work, it is by no means to be supposed that he was a mere imitator of Pasteur. Lister was the first to visualise the enormous practical importance of Pasteur's work, and himself was the creator and the greatest exponent of the whole antiseptic advance.

It was also Pasteur's demonstration of specific fermentations that led Davaine (1863) to renew his observations on the bacteridia seen years before by him with Rayer in anthrax blood, and by Pollender and Brauell. Pasteur himself followed all these advances with keen insight and appreciation, and was thereby brought into personal contact with disease processes although he had no medical training. In particular, he spent the later part of his life in elucidating infectious animal diseases like fowl cholera, swine erysipelas, anthrax, and hydrophobia. Not only did he show that these diseases are due to special microbes differing from each other and producing the specific disease, but he was enormously ahead of his time in discovering prophylactic measures by which these diseases can be prevented by inoculation. One of his greatest discoveries—and one which pervades all his later work—was the demonstration that an attenuated living virus, *i.e.* one no longer capable of causing fatal disease—can by inoculation lead to the prevention of fatal disease. As Jennerian inoculation of calf lymph belongs essentially to this category, Pasteur proposed to designate the method by the name "vaccination," Although, in so doing, the etymological significance of the word was lost. Pasteur was the discoverer of extraordinary forms of microbes which live without air—anaerobes—and himself discovered the first disease-producing microbe of this class, namely, *Vibrion septique.* Since his time the knowledge of pathogenic anaerobes has grown to a special department of bacteriology.

By degrees the fundamental doctrine of the specificity of disease became firmly established. The idea first emanated from the fertile mind of P. F. Bretonneau, the French clinician, who in the beginning of the nineteenth century overthrew the prevailing doctrines of Broussais, and showed that diseases vary from differences in *cause* rather than from the *intensity* of the cause or the *environment.* The actual demonstration of specificity in infective disease is one of the great achievements of modern pathology, and was shown in particular by Robert Koch, who in 1876 introduced simple methods for bacterial cultivation which have not been materially altered down to the present time. Koch's principle utilised media (*e.g.* gelatine) which were fluid at one temperature and solid at another. By disseminating the microbes in the fluid medium and suddenly solidifying it the bacteria were, so to speak, imprisoned and started to grow and in this way "pure cultures" were easily obtained. Viewing Koch's pure cultures in London in 1881 in Lister's laboratory at King's College, Pasteur, turning to Lister, said, "C'est une grande découverte." It was the application of Koch's method in his own hands and those of his assistants that, in the decade 1880–1890, revolutionised the subject of disease causation, and led to the discovery of more solid facts than had been possible since the dawn of civilisation.

The discovery of the microbes of tuberculosis, cholera, diphtheria, glanders, and enteric fever in this decade renders it one of the most fertile in the history of medicine, and was the classical period when the science of bacteriology was founded. Since 1890 the current has flowed in another direction, namely, towards the prevention and cure of specific infective disease by specific remedies, and it was here that Pasteur's main work on the effects of attenuated virus led and still leads the way. When one calmly surveys the immense progress of medical science in the last fifty years it will, we think, be admitted by future historians that its progress and success were due largely to the work initiated with so much imagination and carried out with such incomparable technical skill by Louis Pasteur.

Pasteur and Preventive Medicine.

By Prof. J. C. G. LEDINGHAM, F.R.S.

PASTEUR'S life-work is a finished symphony, a science in miniature, and it is, perhaps, not generally appreciated that the Master was well advanced in years when he commenced the final chapter which witnessed that remarkable series of experiments in prophylactic immunisation which culminated in his dramatically successful attack on rabies. This crowning victory over a dreaded scourge was rendered possible by Pasteur's profound faith in the immunising powers of attenuated viruses—a faith which his previous experience with fowl cholera, swine erysipelas, and anthrax had but strengthened. It was in essence the faith of Jenner.

Pasteur commenced the final chapter of his life, which he devoted to preventive medicine, as the complete comparative pathologist and he remained one to the end. It is true that fowl cholera and anthrax were among the few infections of which the microbic agents were at least known, though meagrely studied. The great chain of discoveries in the causation of human infections dating from the early 'eighties, and inspired by the genius of Koch's pure culture studies, was yet unforged, and in that work Pasteur and his school took little share. To Pasteur the accurate knowledge of a virus was simply a stimulus to attack the disease on the preventive side, but neither to him nor to his great contemporary Lister was this stimulus an essential one. If a virus could be demonstrated and cultivated outside the body, so much the better. Attenuation was all the simpler. So when he came to rabies, ignorance of the actual virus did not deter him from the attempt to attenuate its virulence by an ingenious method of his own and to render it amenable for prophylactic use. His demonstration of the predilection of rabies virus for brain and spinal cord supplied the key that opened the secret door.

It is fortunate, perhaps, that Pasteur's activities in preventive medicine were solely concerned with veterinary disease. There he had full scope for animal experiment on the large scale and he could assess at will the value of a prophylactic measure under controlled experimental conditions. That day at the farm of Pouilly-le-Fort when he arrived to find the vaccinated sheep and cattle alive and well, while all the unvaccinated controls were dead or dying of anthrax, must have been a glorious date in a calendar that held many such. But all systems of immunisation, whether in man or animal, when brought to the test of the field experiment, reveal their relative value, and Pasteur's essays have been no exception to the rule. His guiding principles in immunisation have, however, easily stood the light of fifty years and never were they more keenly debated than to-day, when the factors that control the vagaries of bacterial virulence are just beginning to be understood. Pasteur was, perhaps unconsciously, the first exponent of bacterial variation, a field of work that exercises many minds to-day and bids fair to yield a rich harvest. Attenuation was secured by Pasteur in several different ways, in fowl cholera by prolonged incubation of the virus, in swine erysipelas by passage through another animal species, and in anthrax by altering the temperature of incubation.

What amount of success has been achieved since then in prophylaxis against human infections is due to the substitution of the killed for the attenuated live virus—certainly an expedient, but very possibly a retrograde, modification of Pasteur's principle. The solution of the mysteries of attenuation, to which renewed study is being devoted, may yet open up new vistas in prophylaxis and in serum-therapy, but to Pasteur's pioneer work in this field, preventive medicine must for ever pay homage.

Pasteur in Crystallography.

By Dr. A. E. H. TUTTON, F.R.S.

IT is very rare indeed that a scientific man of our time is equally distinguished for his researches in both the great fields of natural science, the chemico-physical and the biological, yet this is true of Louis Pasteur. His fame as a chemical crystallographer was assured for all time by his brilliant discovery, as a young man of twenty-six in the year 1848, of the true nature of tartaric acid, by his measurement of the crystals of the two optically active varieties, and by his revelation of the connexion between right- and left-handedness of crystalline form (enantiomorphism) and optical activity. This particularly interesting property of rotating the plane of polarisation of a ray of polarised light has been said by Prof. Percy Frankland to be "the distinctive seal of nobleness exhibited by the aristocracy of chemical compounds." The distinction achieved by Pasteur in the biological world, great as it is, rendering his name a household word among us and one to be blessed by generations yet to come, is thus at least equalled by his pioneer services to crystallography.

It is somewhat remarkable that Mitscherlich in the

year 1819 should have made his celebrated discovery of isomorphism during his first research, that Scheele in 1769 should have isolated tartaric acid as the result of *his* first investigation, and that Pasteur in 1848 should have discovered the great principle of enantiomorphism and the generalisation connecting it with optical activity now known in crystallography as Pasteur's Law, as the result of his earliest research. Young post-graduates setting forth on their first steps in scientific research may find great encouragement from these interesting facts.

In the year 1819 an acidic substance greatly resembling the tartaric acid discovered by Scheele had been found in the grape-juice vats of Thann in Alsace, and in 1826 it was investigated by Gay Lussac, who was obliged, however, to confess himself puzzled as to the nature of the substance. Gmelin also examined it in 1829, with a similar result, but he at least gave it a name, Traubensaure—acid of grapes—which was translated as racemic acid in France and England. Subsequently Berzelius tackled it, and got so far as to prove that its empirical composition was $C_4H_6O_6$, the same as that of Scheele's tartaric acid, this observation being indeed the introduction of the principle of isomerism into chemistry. Shortly afterwards Biot, who subsequently became the close friend and admirer of Pasteur, in the course of his pioneer work on the rotation of the plane of polarisation of light by certain specific substances, examined for rotatory power both this racemic acid and tartaric acid. He found that the latter, both the crystals and their solution in water, rotated the plane of polarisation to the right, but that racemic acid was optically inactive.

It was at this juncture that Pasteur took up the study of the subject, concentrating his attention first on racemic acid and its salts. One of the most readily obtainable is sodium hydrogen racemate, and when to the solution of this salt in water ammonium hydrate is added, the salt sodium ammonium racemate crystallises out on standing, its composition being $C_4H_4O_6 \, NaNH_4 . 4H_2O$. It was in examining these crystals that Pasteur made the initial discovery which led to all the rest. For he observed that in some of the crops obtained all the individual crystals were either right-handed or left-handed, the two varieties being, when analogously equally developed, the mirror-images of each other. Moreover, crystals of either kind at will could be obtained from a metastable (saturated at 28° C. and cooled to ordinary temperature) solution of the salt by touching the solution with a crystal of the desired variety. The crystals belong to the rhombic bisphenoidal class 6, the faces of complementary bisphenoids being present on opposite sides on the two kinds of crystals.

On collecting crystals of each variety apart, redissolving them and recrystallising, the fresh crystals proved to be of the same kind as those dissolved; and on precipitating a solution of each variety with a soluble lead salt and decomposing the precipitated lead salt by means of sulphuretted hydrogen, Scheele's ordinary dextro-tartaric acid was obtained in one case, while the other variety gave quite a new form of tartaric acid, the crystals and solution of which rotated the plane of polarisation to the left. This was, in fact, the isolation by Pasteur of lævo-tartaric acid. Further, on mixing the two separate acids thus derived, right-handed and left-handed, he noticed that heat was evolved, a molecular combination of the two varieties occurring, the product being racemic acid, which crystallised out with a molecule of water of crystallisation, $C_4H_6O_6 . H_2O$. Thus he discovered the true nature of racemic acid, namely, that it is a molecular compound of the two optically active tartaric acids, the two varieties exactly neutralising each other and producing thereby optical inactivity.

Pasteur must have had some considerable crystallographic knowledge, for he measured crystals of dextro-tartaric acid and made observations with lævo-tartaric acid which were adequate to prove that its crystals were the mirror images of those of the ordinary dextro acid. The crystals belong to the sphenoidal class 4 of the monoclinic system. Typical crystals of the two varieties are shown in the accompanying Figs. 1 and 2, and it will be clear that the dextro variety, Fig. 1,

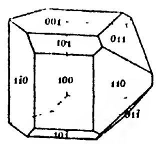

Fig. 1. Dextro-tartaric acid.

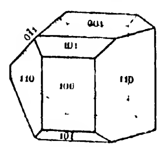

Fig. 2. Lævo-tartaric acid.

exhibits the right clino-prism {011}, while the lævo variety, Fig. 2, has only the left clino-prism {011} developed, of the two possible sphenoids, the distinctive forms of this class of lower than holohedral symmetry.

These crystals of the two optically active tartaric acids are anhydrous, corresponding to the formula $C_4H_6O_6$. On the other hand, racemic acid, as already mentioned, crystallises with a molecule of water, and the crystals are quite different and of only one kind, belonging to the pinakoidal holohedral class 2 of the triclinic system, as subsequently established by De la Prevostaye. The combination of the two optically active varieties, however, is so loose that the separation into the two kinds already described is possible, under the specific conditions stated.

In the year 1850 Pasteur discovered yet a fourth variety of tartaric acid—meso-tartaric acid—which is truly and permanently without action on the plane of polarisation of light, and so is quite unresolvable into two optical antipodes. This further fact threw great light on the subject, and eventually Pasteur showed that the explanation of the whole matter is to be found in the symmetry or dissymmetry of the chemical molecules themselves. Not only is the empirical formula the same for all, but the constitutional formula written in one plane is also identical, namely,

$$\begin{array}{l} CHOH{\cdot}COOH \\ \,| \\ CHOH{\cdot}COOH \end{array}$$

; but the atoms or groups are differently disposed in space in these different physical isomers. Physical isomerism is possible when the substance possesses what has since been called an asymmetric carbon atom, an atom of carbon of which the four tetrahedrally disposed valency bonds are satisfied by four different elements or groups. Optical activity is usual in all such cases, but it has more recently been shown that it is not the absolutely essential condition for the development of optical activity, the absence of second order symmetry elements (planes of symmetry or second order axes) and possession of only first order (axial) symmetry being the more truly determinative condition for the development of two enantiomorphous varieties of physical isomerides and of their accompanying opposite optical activities. Tartaric acid, however, does possess this essential condition, and it has also two asymmetric carbon atoms, namely, those in the two CHOH groups (starred) of the constitutional formula

$$\begin{array}{l} {}^{*}CHOH{\cdot}COOH \\ \,| \\ {}^{*}CHOH{\cdot}COOH \end{array}$$

, and the group of atoms in one half-molecule may be either symmetrically disposed with respect to those of the other half-molecule or differently disposed. When they are symmetrically arranged, internally compensated, the whole molecule is optically inactive, this corresponding to the case of the truly inactive tartaric acid; when they are unsymmetrically arranged they are so in either a right- or a left-handed manner, the crystals being helically constructed (recently confirmed by X-ray analysis) as a right or left screw, giving rise to the two optical enantiomorphous antipodes, as in the case of dextro- and lævo-tartaric acids. Racemic acid, the molecular combination of the two last mentioned, is the case of external compensation as regards the molecules.

The work during the present year of Mr. W. T. Astbury in the laboratory of Sir William Bragg, on the X-ray analysis of tartaric acid, the results of which have just, most opportunely, been communicated to the Royal Society, has proved without a shadow of doubt that the four atoms of carbon in the molecule of ordinary dextro-tartaric acid are, in very truth, spirally arranged. This is a most welcome confirmation of Pasteur's great work on the very eve of his centenary.

The principles on which the whole of these results are based were eventually summarised in what has since become known as Pasteur's Law, which may be briefly stated thus:—"If the atoms of a chemical molecule be dissymmetrically arranged, this molecular dissymmetry implies the possibility of the existence of two oppositely complementary configurations of the molecule. Both varieties have the same chemical properties, and they are endowed always with equal but oppositely directed rotatory power. The presence of molecular dissymmetry therefore reveals itself by this rotatory power of the molecules and is wholly determined by their chemical constitution. When the atoms of a chemical molecule are dissymmetrically arranged, the fact is at the same time betrayed by the occurrence of the two varieties in complementary non-superposable crystalline forms, possessing screw axes of opposite winding."

This purely chemical and crystallographic work of Pasteur was connected with his later bacteriological and zoological work by the further pioneer observation that when the spores of the ferment *Penicillium glaucum* were added to a solution of racemic acid containing a small quantity of phosphates (which appear to be essential to the life of the organism), the dextro component of the molecular compound of the two varieties of optically active tartaric acid is somehow isolated and eaten up by the organism, leaving the lævo component untouched so long as any dextro acid remains. Why this is so is a mystery still, connected with life itself. By arresting the fermentation at the psychological moment, the residual lævo variety can thus be isolated and crystallised out tolerably pure, and its isolation was, as a matter of fact, thus effected for the first time in yet a second manner by Pasteur, and its crystals shown by him to be the mirror-images of those of Scheele's ordinary dextro-tartaric acid.

This observation by Pasteur has developed into a general method for the fissure and separation of the two separable varieties of a racemic compound—for many such compounds have since been discovered—and for the isolation of one of them, the other being chosen in some mysterious way for preferential destruction by the organism, in assimilating it for its own nourishment and reproduction. Thus the great value of the classic work of Pasteur on the tartaric acids lies in the fact that this group of compounds proved to be but a type of a large class of substances, which exhibit physical isomerism in two enantiomorphous varieties that are optically active in opposite directions and

combine molecularly to form compounds of racemic character. His methods and his law have thus come to be of wide, indeed general, application to all such cases. With regard to the deeply interesting question why so slight a difference of nature, between two varieties of a substance, as a mere difference of type of helix—right- or left-handed—along which the atoms are arranged, should be a sufficient cause for the different behaviour of a living organism brought into contact with it, remains still unsolved. The fact, however, has been amply confirmed over and over again, as well as by Emil Fischer's results on the selective fermentation of sugars by yeasts, so that it appears as if the action of every living organism corresponds to only a particular arrangement of the atoms in a chemical molecule. Pasteur himself says (1860), and with these words of still valid portent this article may well conclude: "Il y a là des mystères, qui préparent à l'avenir d'immenses travaux et appellent dès aujourd'hui les plus sérieuses méditations de la science."

Pasteur's Early Research in Pure Chemistry and Fermentation.

By Prof. ARTHUR HARDEN, F.R.S.

THE purely chemical researches of Pasteur, undertaken when he was a young man of twenty-two years of age, were all comprised within the epoch 1844–1860, during the latter part of which he was also actively engaged on his great work on fermentation. Pasteur's fundamental contribution to pure chemistry, the idea of the asymmetric arrangement of the atoms within the molecule, has proved to be one of the most fruitful conceptions of the science. The experimental methods which led to its development have provided chemists with a weapon by which many of the most difficult and subtle problems have been successfully attacked; a weapon which still maintains its place in the armoury of the chemist and is every day turned to fresh account.

Pasteur's fundamental experiment on the resolution of the racemates, and the dramatic scene in which his great discovery was recognised by the veteran Biot, are among the classics of chemical literature. The thrill accompanying the culmination of this his first successful research, the memory of that joyous nervous excitement which prevented him from again looking into the polarimeter, must have always remained vividly present to his mind and can never have been effaced even by the ever-increasing flood of discoveries which marked his later years.

Stereochemical relations are now so well established and so universally admitted that it is difficult to realise the intrepidity of Pasteur's theoretical deductions. He saw at once that the asymmetry of his two tartaric acids would lead them to form different compounds with an asymmetric (optically active) base. On making the experiment, after many abortive attempts, he at length had the satisfaction, second only to that experienced at the successful resolution of the racemates, of obtaining crystals of pure cinchonicine lævotartrate by the crystallisation of the racemate of this optically active base. Thus was established the classical chemical method for the resolution of asymmetric compounds.

It is of special interest, in view of the later direction of Pasteur's scientific work, that he at once perceived the bearing of his new discoveries on the chemistry of the living organism. It was only among the products of vegetable and animal life that he found substances the molecules of which were asymmetric. In the mineral kingdom and among the synthetic products of the organic chemist molecular symmetry held undisputed sway. He therefore regarded the living organism as the sole source of asymmetric molecules, the cell acting as "a laboratory of asymmetric forces." Observation soon reinforced these theoretical ideas. Struck by the "spontaneous" fermentation of a solution of ammonium tartrate, he transferred a drop of the fermenting liquid to a solution of ammonium racemate and found that when the fermentation which ensued had ceased the lævotartrate was quite intact whereas the dextro-acid had disappeared. "Thus" says Pasteur, in his lectures on Asymmetry,[1] 1860, "the conception of the influence of the molecular symmetry of natural organic products is introduced into physiological studies through this important criterion (optical activity), which forms perhaps the only sharply defined boundary which can at the present day be drawn between the chemistry of dead and living nature."

It was, according to Duclaux in his charming biography "Pasteur, histoire d'un esprit," another aspect of the relation between organisms and the asymmetry of their products which led him to the study of fermentation, his next great field of discovery. Amyl alcohol, the optically active constituent of fusel oil, was at that time universally supposed to be derived from the sugar, although it is now known, through the brilliant researches of Felix Ehrlich, to be a product of the decomposition of protein. This substance was assumed by the opponents of the vitalistic theory of fermentation, which had been based on the discovery of the living nature of yeast in 1837, to owe its optical activity to the parent molecule of sugar from which it

[1] Quoted from Frankland's Pasteur Memorial Lecture, Jour. Chem. Soc., 1897.

was derived. Pasteur, in view of his experiments on the decomposition of active substances, which gave rise to inactive products, could not accept this idea, and, regarding living beings as the sole source of asymmetric molecules, was strongly inclined to the belief that in the production of the active alcohol a living organism must have intervened. With characteristic energy he commenced the study of the lactic and alcoholic fermentations, the results of which (published in 1857 and 1860) were of such far-reaching and unexpected importance. The lactic organism—hitherto not only unknown but almost unsuspected—was discovered and shown to be the specific cause of the chemical change of sugar into lactic acid. In the same way he showed that living yeast was the cause of the alcoholic fermentation of sugar, and triumphed over the objections and arguments of Liebig by growing yeast in a synthetic medium, which contained only mineral salts and well-known pure stable organic substances. By this bold stroke Liebig's contention that the ferment was an unstable substance formed by the action of air on plant juices containing sugar was totally overthrown, and with it fell his theory of fermentation, according to which the instability of the ferment was transferred to the molecule of the sugar.

Pasteur, who had at once discovered that carbon dioxide and alcohol were not the only products of alcoholic fermentation, but that succinic acid and glycerol were always formed, in addition to the new-born cells of the organism, regarded fermentation as a physiological act by which the yeast acquired some material essential for its life from the fermented sugar. No fermentation without life was his deliberate conclusion. He was not, however, heedless of the attempts made by Traube and others to attribute fermentation to the presence of ferments in the living cell, and we are told by Roux that he made many vain attempts by grinding, freezing, and plasmolysing yeast cells to obtain evidence as to the existence of such a ferment. It is strange to reflect that it was in all probability an unfortunate selection of a yeast unsuitable for the purpose of such experiments that led to these repeated failures, and that but for this he might have anticipated Buchner by a quarter of a century and have advanced one step further towards the elucidation of this complex problem.

Buchner's great discovery (1897) showed that Pasteur had gone too far in his generalisation. The act of fermentation was shown to be a chemical change produced in the presence of a non-living agent, separable from the cell, an agent the complexity of which still awaits complete resolution. It is the production of this essential instrument of change that is a function of the living cell, and the physiological significance of the act of fermentation is, in all probability, not the acquisition of material but of energy.

It was Pasteur's great achievement in these researches to have cleared the ground for future work. The old indefinite ideas were shown to be wrong and it was definitely proved that each different type of fermentation was due to a specific organism. Here the modern study of fermentation begins, and every worker on this subject must look back with gratitude to Pasteur's researches as the ultimate inspiration of his labours.

Pasteur and the Fermentation Industries.

By Prof. A. R. Ling.

Louis Pasteur, one of the great figures in the scientific world of the nineteenth century—and there were giants in those days—was a man whose studies covered a more extensive range than those of perhaps any other scientific man of his time, while his researches have had a correspondingly far-reaching influence on both pure and applied science. Pre-eminently an academic worker, he was able to apply his discoveries to preventive medicine, surgery, agriculture, bacteriology, and the fermentation industries. Some of his later work was, indeed, actually taken up with a distinct practical objective. But the success achieved in his researches in applied science must be attributed solely to his profound studies in pure science, without which he would not have been in possession of the means of attacking problems in such a manner as to obtain results of direct benefit to mankind. In this connexion it may be pointed out that one of the outstanding features of his genius was his remarkable prescience, which enabled him to turn purely academic work to utilitarian ends. As an example of the practical trend of his mind, his remarks in the preface to his celebrated "Études sur la bière" (English Translation) may be quoted:

"I am convinced," he says, "that I have found a precise, practical solution of the arduous problem which I proposed to myself. . . . These new studies are based on the same principles which guided me in my researches on wine, vinegar, and the silk-worm disease—principles, the application of which are practically unlimited. The etiology of contagious diseases may, perhaps, receive from them an unexpected light."

If we are to understand the causes which led to Pasteur's association with the fermentation industries, we must consider briefly his early work. It is an old tale, yet one worthy of repetition. From the College

of Arbois, he proceeded to Besançon and entered the École Normale in 1843. Here, as a student of chemistry, he came under the influence of Balard and of Dumas, while his attention was turned to crystallography by M. Delafosse, assistant to Haüy. When in 1844 Biot presented to the French Academy of Sciences a paper by Mitscherlich, in which it was stated that the sodium ammonium salts of racemic acid and of ordinary tartaric acid respectively were identical not only in chemical composition but also in crystalline form, Pasteur, who seems to have been guided by Sir John Herschel's discovery in 1820 of the opposite hemihedral relationship of dextro- and lævo-rock crystal or quartz, demonstrated to Biot's satisfaction that the crystals of sodium ammonium racemate also exhibited opposite hemihedrism. He was able, in fact, to separate by selection those crystals derived from ordinary dextro-tartaric acid and those derived from the hitherto unknown lævo-tartaric acid. Pasteur was, however, in the first place a chemist, and not long afterwards he discovered a chemical means of resolving racemic acid into its enantiomorphic isomerides by fractional crystallisation of its salts with certain optically active bases. This was followed later by a third, a biochemical method, which depended on the fact that the green mould *Penicillium glaucum*, when grown in the presence of racemic acid, ferments the dextro-acid preferably to the lævo-acid.

It is possible that this last-mentioned discovery was the means of leading Pasteur into the domain of biology, in which branch of science he was destined to make such brilliant discoveries. The commencement of his researches on yeast dates, however, from the year 1856, when he occupied the position of Dean of the Faculty of Science at Lille. Here he was consulted by a local distiller named Bigo on certain difficulties encountered in the manufacture of alcohol from beetroot.

Before describing Pasteur's final conclusions on the nature of yeast and of alcoholic fermentation, it will be necessary to take a brief retrospective glance on the state of our knowledge prior to the period with which we are dealing.

The cellular form of yeast had been established so long ago as the seventeenth century by Anton Van Leeuwenhoek, and in 1836 Cagniard-Latour observed that yeast cells are susceptible of reproduction by a sort of budding, while a similar observation was made about the same time by Schwann. Little account was taken of these observations, however, and alcoholic fermentation was explained by the theories of Berzelius and of Liebig, the former regarding it as a catalytic phenomenon, and the latter as one in which the ferment (yeast) was a substance which decomposed readily, and in so doing set in motion the molecules of the fermentative matter.

In the year 1856, Pasteur commenced his studies on yeast and on alcoholic fermentation, and from that time dates his celebrated controversy with Liebig, which raged with fury up to the year 1861, when Pasteur had established anaerobic growth in certain micro-organisms, and had finally proved that yeast is a living organism. His further conclusion was that alcoholic fermentation is a phenomenon coterminous with the life of yeast. Still Liebig maintained his view tenaciously, and only modified it in 1870.

"It is possible," said Liebig, "that the only correlation between the physiological act and the phenomenon of fermentation is the production in the living cell of the substance which, by some special property analogous to that by which emulsin exerts a decomposing action on salicin and amygdalin, may bring about this decomposition of sugar into other organic molecules; the physiological act, in this view, would be necessary for the production of this substance, but it would have nothing else to do with fermentation." To this Pasteur replied, "Ici je ne contredirais encore pas."

Liebig's final hypothesis was therefore similar if not identical with that of Berzelius, and we shall now see how it was reconciled ultimately with the views of Pasteur. Berthelot in 1858 suggested that fermentation was the result of unorganised ferments (enzymes) secreted by the yeast, but to this Claude Bernard objected in 1860. Brefeld in 1874–75 considered that it was only when all the free oxygen in a fermentable liquid had been removed that the yeast cells commenced to excite fermentation, which he believed to be due to an enzyme. Pasteur in the course of his work had tried in vain to isolate this enzyme, and he favoured the view that fermentation was a vital act of the yeast cell. In 1897 E. Buchner extracted the enzyme of alcoholic fermentation from yeast and called it zymase.

Pasteur's further work on fermentation is embodied in his celebrated treatise, "Études sur la bière" (1876).

"Our misfortune," he says, "prompted me with the idea of these researches. I undertook them immediately after the war in 1870, and have since continued them without interruption, with the determination of perfecting them, and thereby benefiting a branch of industry wherein we are undoubtedly surpassed by Germany. I am convinced that I have formed a precise, practical solution of the arduous problem which I proposed to myself—that of a process of manufacture, independent of season and locality, which should obviate the necessity of having recourse to the costly methods of cooling employed in existing processes, and at the same time secure the preservation of its products for any length of time."

Pasteur's views on alcoholic fermentation are somewhat difficult to understand; hence he met with many

opponents to his theories. They may be summed up in his famous dictum—"Fermentation is life without air." He recognised, however, the necessity for the presence of dissolved oxygen in a liquid undergoing fermentation. Were it not, he says, for the oxygen which yeast meets with dissolved in the wort and also that which it seizes upon when manipulated in contact with air—for yeast which has been deprived for some time of free oxygen absorbs this gas with the greatest avidity—it would soon cease to act as a ferment. Pasteur, therefore, lays the greatest stress on the need for aëration as a preliminary to fermentation, and this was one of the most valuable of his suggestions relating to fermentation technology.

According to Pasteur, however, yeast is an amphibian living the aerobic life of an ordinary fungus, in which case in the presence of free aëration the maximum cell reproduction is obtained with a minimum of alcoholic fermentation or none at all, and secondly, as an anaerobe in which alcohol production is at its maximum together with a more limited cell reproduction. But in order to ensure both these results it is necessary for the yeast to have fixed a certain quantity of oxygen. It is impossible in the space at our disposal to deal with the work of Adrian Brown, of Horace Brown, and of A. Slator. The question is still in a sense in the melting-pot, but it would seem that Pasteur's views are likely to be proved to be in the main correct.

No better tribute could be paid to the services rendered by Pasteur to the fermentation industries than by quoting the words of Dr. Horace T. Brown.

"The current of my thoughts was entirely changed by the perusal of the early work of Pasteur, and when in 1867 . . . the celebrated 'Études sur le vin' came into my hands, I became thoroughly imbued with the new biological aspects of fermentation. There are probably but few here who can . . . fully realise what it meant to have the vague and utterly sterile ideas of the Liebig school replaced by the clear and logical demonstration that fermentations are phenomena correlative with the vital action of specific organisms."

Centenary Celebrations.

THIRTY-ONE years ago, in the issue of NATURE for March 26, 1891 (vol. 43, p. 481), Sir James Paget contributed to our Scientific Worthy series an illuminating account of the career and scientific researches of Louis Pasteur. His son, Mr. Stephen Paget, in an article in the present supplement, makes clear the full meaning of Pasteur's work as the founder of bacteriology, and expresses the admiration of the scientific world for the fertile fields of study opened by him in many departments of natural knowledge. This and other contributions with which we have been favoured by Profs. Bulloch, Ledingham, Harden, Ling, and Dr. Tutton, will, we hope, be accepted as a modest tribute to the genius of an apostle of science and supreme benefactor of the human race.

The event, of course, which we desire to mark by the publication of this supplement is the centenary of Pasteur's birth at Dôle on December 27, 1822. The French Academy of Medicine will celebrate the centenary on December 26 by a special meeting, which will be addressed by several distinguished men of science. On the following day there will be a similar assembly at the Pasteur Institute, to which the Academy of Medicine will send representatives. In the United States of America the New York Academy of Medicine is organising an exhibition of books, manuscripts, pictures, and so on, illustrative of the life and work of Pasteur. The exhibition will be opened formally on December 27, when a number of distinguished American medical men will give addresses on various aspects of Pasteur's work. In Great Britain the Alliance Française is entertaining MM. Vallery-Radot, descendants of Pasteur, in February, and Dr. Pasteur Vallery-Radot is to give an account of his grandfather's life and work.

Probably the most important event will be the great exhibition of hygiene and bacteriology which is being organised by the town and University of Strasbourg, with the concurrence of the Pasteur Institute and the approval of the family of Pasteur. There, from May till October next, it is proposed to have exhibits illustrating the advances of science made as a result of Pasteur's far-reaching discoveries, while congresses for discussing questions relating to the prevention of disease will be held. It is hoped that it will be possible to preserve a section of the exhibition as a permanent Museum of Hygiene, principally for demonstrating the best methods of dealing with public water supplies and similar matters.

On the opening day of the exhibition there will be another interesting ceremony in the form of the unveiling of a monument to Pasteur which is being erected at the University of Strasbourg. The monument will be an obelisk carrying a medallion of Pasteur. It has been provided out of funds subscribed from many countries, towards which a committee under the presidency of Sir Charles Sherrington, president of the Royal Society, was able to forward a substantial contribution from this country. It is expected that a large and representative gathering from the scientific world will be present on the historic occasion of the unveiling ceremony.

The French Government will be represented at the various official celebrations. In addition, the Paris correspondent of the *Times* states that the president of the senatorial commission on education has announced that on the evening of December 27 the bells of Dôle, Pasteur's birthplace, will be rung for the two minutes preceding 5 o'clock, and that the bells of the Franche-Comté from the plain of the Saône to the crests of the Jura will reply. He has also suggested that all the bells in France should be rung at this time in commemoration of the great work for humanity accomplished during the past century.

NATURE

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE.

CONTENTS.

Parliamentary Aid to Universities.

THERE is need for a clear definition of the present position in regard to Government grants for university education in Great Britain. Statements of a seemingly contradictory nature have been made, and it is not surprising that misunderstandings have arisen. On one hand we have the fact that the parliamentary votes for university education are reduced from 1,500,000*l.* to 1,169,000*l.*, while on the other we are told that the grants to the universities this year will be no less than last and that the annual grants are to be maintained at their present scale. The real facts of the situation have become obscured by certain complexities, arising mainly from the difference between the Government financial year and the academic year, and from the exclusion this year of the Irish grants.

The first announcement of the Treasury's decision to reduce Government aid to university education was a simple one, to the effect that Parliament would be asked to vote for this purpose only 1,200,000*l.* instead of the million and a half voted last year. But the larger amount of last year included provision for Irish universities, amounting altogether to 111,000*l.* (not counting an emergency grant to Trinity College, Dublin), while this year the sum reserved in the estimates—namely, 1,169,000*l.*—makes no allowance for the Irish universities. The amount available for university education in Great Britain therefore falls, if the estimates are approved by parliament, from 1,389,000*l.* to 1,169,000*l.*—that is, by 220,000*l.*—the sum mentioned by the president of the Board of Education in his recent speech at Bristol.

The net reduction in the grant is happily less than was at first anticipated. But, even so, it is difficult at first sight to reconcile a loss of over 220,000*l.* with Mr. Fisher's remark to the effect that there would be

no real reduction of the amount of parliamentary money placed at the disposal of the universities this year. The explanation is to be found in the fact that the grants to the universities are made in respect of the academic year ending on July 31, while the parliamentary votes are for the year ending on March 31. Thus the grants for this present academic year are based on the parliamentary vote for the financial year which came to an end on March 31 last, and that was the year in which the vote was at its maximum. The grants for this academic year naturally show no reduction. On the contrary, they have increased because they are based on the increased vote.

The fall in the grants to universities will, of course, occur in the academic year ending in July 1923, and will be the direct and inevitable result of the reduction of the parliamentary vote for the financial year ending in March next. The reduction in the grants assigned to the various institutions in the financial year 1922–23 is seen to be no less than 113,905*l.*; but the loss in the academic year 1922–23 will be much greater than this, the difference being due to the fact that the amounts of grant shown in the estimates for 1921–22 are a good deal less than the sums actually received by the universities in the academic year 1921–22, being made up of three parts, namely:

(*a*) "Annual grant" for the second half of the academic year 1920–21 (before the vote had been increased by 500,000*l.*).

(*b*) "Annual grant" for the first half of the academic year 1921–22 (after the increase in the vote).

(*c*) What has been called a "non-recurrent grant," but might more correctly be termed a recurrent grant of variable amount.

It is obvious that, as the first of these three factors is based on the earlier low rate of grant, the total of the three will be considerably less than the aggregate of the grants received by the universities in the academic year 1921–22. Although exact figures are not available, there is reason to suppose that the actual fall in the academic year 1922–23, as compared with the present academic year, will be not far short of 250,000*l.*

If the smaller vote proposed for the current financial year is approved by Parliament, a large reduction in the university grants next academic year is a result which cannot be avoided. But even so, it may be urged, the universities will still receive considerably more than in 1920–21. This view, however, ignores two important considerations. First, the increase in the vote in 1921–22 was justified by the pressing need of the universities for additional aid, and the only reasonable ground for criticising it was that it was on too small a scale. Second, the increased vote encouraged the University Grants Committee to add to the grant list certain institutions—notably Oxford and Cambridge Universities and the clinical units of the London Medical Schools—which had not previously figured on the list. These new commitments, totalling approximately 120,000*l.*, undertaken on the strength of the enlarged vote, remain a permanent charge on the reduced vote.

The statement which has been made, and has given rise to some misconception, that the annual grants to the universities will be maintained at their present level, depends for its truth on what is little more, in fact, than a technicality.

In allocating to the universities the money voted by Parliament, the University Grants Committee has adopted the practice of giving only part of the money in the form of "annual grants" and the remainder (except what is kept in reserve) in the form of grants (called "non-recurrent"), the amount of which is decided in the case of each university each year. Whatever may be thought of this method of allocating the money voted by Parliament, and whatever these grants may be called, the fact remains that they have been made this year and in previous years, and that they will not be made next year. A reduction of a quarter of a million in the income of the universities is no less a reduction of a quarter of a million because the money lost has not been technically called an "annual grant." It must also be understood that it is not because the universities have not needed the whole of the money voted by Parliament that some of it has been treated by the "non-recurrent" method and some kept in reserve. The whole of the money, and much more than the whole of it, is sorely needed by the universities, and no amount of discrimination between grants of one denomination and grants of another denomination can alter the fact that the amount coming to the universities next year will be about a quarter of a million less than the amount received this year. Such a reduction must deal a very serious blow at the efficiency of university education in Great Britain.

The New Astronomy.

The New Heavens. By Prof. G. E. Hale. Pp. xv+88. (New York and London: C. Scribner's Sons, 1922.) 7*s.* 6*d.* net.

IT is impossible not to be impressed by the wonderful story of astronomical achievement told by Prof. Hale in felicitous language in this little volume. Before the invention of the telescope not more than about six thousand stars had ever been seen by human eyes, and less than half this number at any one time. The small telescope, with an object-glass an inch or

so in diameter, used by Galileo in 1610, brought within the range of vision stars down to magnitude 10·5, numbering about five hundred thousand. The 60-inch reflector of the Mount Wilson Observatory, Pasadena, of which Prof. Hale is director, reveals stars of the 18th magnitude, and the 100-inch carries the sounding-line still further, while with both instruments many stars can be photographed which the eye cannot see directly, the photographic limit with four or five hours' exposure being about the 20th magnitude.

The expansion of the stellar universe as regards the number of stars in it which can be seen or photographed represents, however, only a small part of modern astronomical discovery. The test of a telescope is its resolving power, and this is expressed with sufficient accuracy by the relation $5''/d$, where the numerator is the normal angular limit of separation of a double star and d is the diameter of the object-glass in inches. The separating power of the 36-inch refractor of the Lick Observatory is thus $0''\cdot14$, and that of the 100-inch of the Mount Wilson Observatory $0''\cdot05$. By the use of the interferometer, the latter limit is reduced to $0''\cdot02$, and this increase in resolving power was established by observations of Capella. More than twenty years ago, this star was found by Campbell and Newall to be a spectroscopic binary (that is, to consist of two stars in motion about a common centre of gravity and so close together that the system is known to be duplex only by detecting differences, due to orbital movement, exhibited by the composite spectrum), and determination of the orbit showed that the separation of the components could not exceed $0''\cdot06$. It was, therefore, within the theoretical limit of separation into its components by the use of Michelson's interferometer on the 100-inch telescope of the Mount Wilson Observatory. Observations made at the end of the year 1919 and the beginning of 1920 confirmed the accuracy of this conclusion, and the distance between the two stars of the pair was found on several occasions to be about $0''\cdot045$.

The capacity of the interference method was thus established by these observations with a test-object among the stars. Thirty years previously the method had been used to determine the diameters of Jupiter's chief satellites, but it was only when the 100-inch telescope had been completed that Prof. Hale suggested the application of the principle to the measurement of diameters of stars—a more difficult problem than that of separating close doubles. Prof. Eddington, in his presidential address to Section A of the British Association in 1920, gave the probable angular diameters of some stars and remarked that "the star with the greatest apparent diameter is almost certainly Betelgeuse, diameter $0''\cdot051$." Measurements with the 20-foot interferometer on December 13, 1920, gave an apparent diameter of $0''\cdot047$, which is as striking a confirmation of theoretical deduction by observed result as that represented by the discovery of the planet Neptune. The parallax of Betelgeuse is uncertain, but there are reasons for believing it to be about $0''\cdot02$, which would make the diameter of the star about 215,000,000 miles, or 250 times greater than the diameter of the sun. Antares has similarly been found to have a diameter of 400,000,000 miles and Arcturus of 21,000,000. These stars are in an early stage of stellar evolution—attenuated masses of matter low down on the ascending side of the temperature curve of Lockyer's meteoritic hypothesis—and from "giants" they will be transformed to "dwarfs" as they contract and increase in temperature.

Prof. Hale devotes particular attention to the various stages of growth and decay as indicated by modern studies of stellar types, and shows that they afford no direct evidence in favour of Laplace's theory of the formation of planets in our solar system. Recent investigations have truly revealed "The New Heavens," which he describes so clearly and illustrates so attractively with some of the most remarkable astronomical photographs ever obtained. In his last chapter, entitled "Cosmic Crucibles," he deals particularly with the sun as a star and some of the discoveries in the field opened by him by means of the spectroheliograph, which enabled him to prove that every large sun-spot is an electric vortex producing a magnetic field. As helium was discovered by Lockyer in the sun long before it was isolated on the earth, so in the laboratories of the heavens conditions are now continually being studied which not only enlarge our conceptions of the universe but also provide physicists and chemists with results of outstanding interest and value. No one is more competent than Prof. Hale to survey this great territory of which he is the leading pioneer explorer, and his account of the methods used to examine it and the rich store of new knowledge gathered from it, makes as fascinating a scientific story as ever was told.

R. A. G.

Index Animalium.

Index Animalium. A Carolo Davies Sherborn. Sectio Secunda 1801–1850. Part 1: Introduction, Bibliography and Index A-Aff. Pp. cxxxi + 128. (London: British Museum (Natural History), 1922.) 20*s*.

WE congratulate Mr. C. D. Sherborn on the appearance of the first instalment of the second part of his great work. Since the first part was published in 1902, zoologists have eagerly awaited its continuation,

and we hope that the remainder will now follow with all speed, for the real value of the work can be fully appreciated only in its complete form.

The second part follows closely the form and arrangement of the first. After an explanatory introduction there follows the bibliography, from which the stupendous nature of the task which has occupied the best thirty-one years of Mr. Sherborn's life can be judged. One hundred and thirty-one pages of closely printed matter in small type are required to give the titles of the publications which the author has indexed. Against this, less than two pages of similar type, giving the publications to which the author has not had access (some of these have been seen since the list was set up in print) represent an almost negligible part of zoological literature that has not passed through his hands.

When it is remembered that, but for some 5000 entries made for the author by friends, the whole of the literature has been examined and every entry in the index recorded from the original, arranged, sorted, checked and passed for press by Mr. Sherborn himself, we begin to realise something of the debt which zoology, now and for all time, owes to the author. The personal equation has been reduced to a minimum, and Mr. Sherborn's accuracy, which has stood the severe test of the first part of this index, is a guarantee of the absolute reliance which can be placed on the second part. The author has given valuable bibliographical notes to the literature he has examined, and has smoothed the path of systematic zoologists considerably by indicating where that literature is to be found in England and whether it contains new names or any information likely to be of use.

The "Index Animalium" should henceforth be regarded as the bible of systematic zoology. It seems to us that all the vexed questions of nomenclature and priority could be settled by a reference to its pages, and the time and labours of systematists freed for the more complete examinations of the animals themselves. Acknowledgments are due to the Committee of the British Association and to the Trustees of the British Museum for the financial assistance they have given to this work, and to the latter body for assuming the responsibilities of publication. It is only fitting and proper that the most important centre of systematic zoology in the world should undertake the issue of this invaluable and indispensable work, and we are grateful to the Trustees of the British Museum for having done so.

A word of praise is due, too, to the printers and publishers for the admirable way in which this instalment has been printed and for its freedom from errors. We have detected no typographical mistakes in a fairly close scrutiny. Sir Sidney Harmer in his preface refers to the index as a "labour of love," and we can but inadequately express our thanks to Mr. Sherborn for his magnificent and untiring work. We may, perhaps, be allowed to express our pleasure in the fact that publication is assured and that the results of Mr. Sherborn's work will be preserved in permanent form as a splendid monument to his labours in the cause of science.

Sugar Technology.

(1) *Cane Sugar: A Textbook on the Agriculture of the Sugar Cane. The Manufacture of Cane Sugar, and the Analysis of Sugar-house Products.* By Noël Deerr. Second (revised and enlarged) edition. Pp. viii + 644 + xxix plates. (London: Norman Rodger, 1921.) 42*s.* net.

(2) *The Manufacture of Cane Sugar.* By Llewellyn Jones and Fredric I. Scard. Second revised edition. Pp. xix + 481 + 270 plates. (London: Duckworth and Co., 1921.) 25*s.* net.

(3) *Condensed Description of the Manufacture of Beet Sugar.* By Dr. F. Murke. Pp. v + 175. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1921.) 15*s.* net.

(1) BEARING in mind the importance of the sugar industry to the British Empire, more especially in its relation to sugar cane, it is not surprising, and distinctly comforting, to know that we are so well supplied at the present time with up-to-date literature on the subject. Mr. Deerr's treatise ranks among the most important, occupying as it has done for the last ten years—and if we include his first smaller work we may say seventeen years, not to mention his "Sugar House Control" published in 1900—a unique position, the subject being treated from both the theoretical and practical standpoints. The long experience of the author as a technologist and an experimentalist had qualified him eminently for the task he undertook, while for the past ten years he has added still further to his previous extensive experience by being associated with the sugar industry in Cuba and with a sugar refinery in New York. The first edition of Mr. Deerr's treatise was published in 1911. The present edition covers 52 additional pages, each containing some 11 per cent. more words, in addition to which it has been completely rewritten. The reputation of the author is so well known and generally admitted that it is a guarantee at once that his task has been carried out with thoroughness. It is worthy of note, however, that his MS. has been submitted to the following authorities, to whom he acknowledges his thanks for help and criticism: Mr.

J. Hamill, Dr. C. A. Browne, Dr. C. A. Barber, Dr. E. J. Butler, and Mr. J. P. Ogilvie.

It is impossible to deal in detail with such a voluminous work as the one before us; it must suffice therefore to point out that it deals with all phases of the subject—botanical, agricultural, chemical, and technological.

We cordially recommend the volume to all engaged in the sugar industry, as well as to students who intend entering that industry.

(2) The first edition of Messrs. Jones and Scard's treatise was published in 1909, and the fact that a second edition has now appeared is a fitting testimonial, if one were needed by two such eminent and well-known technologists, of its utility as well as of its appreciation by technologists. Mr. Aspinall in the introductory chapter tells us that the first impression of the work was soon sold, and that the authors preferred to prepare a new and revised edition instead of issuing at once a reprint of the first edition.

The work as now presented is in its original form, but it has been thoroughly revised with some 27 additional pages of text and 26 further illustrations. The volume is a welcome addition to the literature, more especially from the technological point of view. A special feature is the large number of well-executed drawings and plans, numbering in all 270, for which the authors are indebted to the leading engineering firms.

The work will be found indispensable to all engaged in the industry, and we welcome its appearance at a time when it behoves sugar-cane technologists, more especially in the British Dominions, Dependencies, and Protectorates, to cultivate the highest efficiency in their subject, and so make the Empire self-supporting as regards sugar. This is a matter which in the writer's personal knowledge one of the authors at least, Mr. F. I. Scard, has long had at heart.

(3) Dr. Mürke's little book was written in 1903-5, but was not published Recently the author found that it could be brought up to date with very few alterations and additions. While it contains much valuable information, the text is of a sketchy character, the sequence is not well chosen, and some important processes find no mention. This being so, it is scarcely to be recommended as an elementary textbook on the subject. However, the author states that it has been written for "superintendents, engineers, and foremen of the beet sugar factory," and such readers would doubtless be able to follow the text without the aid of illustrations, of which there are none.

If we may be allowed to make a few comments, we would point out that while a concise account is given of Stephan's process of recovering sugar as calcium trisaccharate from molasses, no mention is made that the trisaccharate may be used instead of fresh lime for defecating beet juice. We should have expected to find some reference to the strontium process, but the chapter on the osmose process was scarcely needed; indeed the author himself states that it is almost exclusively an historical one. Most English technologists will prefer the French word "massecuite" instead of "fillmass," the translation of the German "Füllmasse."

Now that we have at least two beet sugar factories at work in the United Kingdom, the demand for works on the subject has naturally increased.

ARTHUR R. LING.

Geology and Tin Resources of the British Empire.

(1) *The Geology of the British Empire.* By Dr. F. R. C. Reed. Pp. viii+480. (London: Edward Arnold, 1921.) 40s. net.

(2) *The Tin Resources of the British Empire.* By N. M. Penzer. (*The Raw Materials of Industry.*) Pp. x+358. (London: William Rider and Son, Ltd., 1921.) 15s. net.

THE geology of our overseas dominions has been described in a host of publications, many of which are difficult of access and full of local and technical detail A compact volume, such as the one under notice, in which the outstanding facts concerning the several regions are presented in brief but readable form, cannot fail to meet with a warm welcome. It will appeal not only to students faced with the difficult task of acquiring a general knowledge of world stratigraphy, but also to all who wish to know the larger geological facts of our Empire abroad.

The subject-matter is based upon a course of lectures which the author has given annually for more than a decade. It has not been hastily compiled, therefore, but is the result of many years of wide reading and judicious condensation. Only those who have tried to assemble within a small compass the salient information concerning the geology of countries like Canada, India, or South Africa will be able to gauge the extent of the author's labours or to thank him adequately for placing the results of them at the disposal of the public.

No description is given of the geology of the British Isles, numerous works on this subject being available. The first region dealt with is the Mediterranean, including Gibraltar, Malta, and Cyprus. Egypt follows, reminding us of the rapidity of Empire changes in these days of awakened national aspirations. In the next chapter, dealing with East Africa, an account is given of the geology of Somaliland, Kenya Colony,

and Tanganyika Territory. Then follow two chapters containing a most useful summary of the geology of the Union of South Africa. Central and South-West Africa and British West Africa are dealt with in the two succeeding chapters, the latter including some pages devoted to the British Cameroons and Togoland. Canada and Newfoundland are dealt with in two chapters occupying sixty pages, and the Indian Empire in two of sixty-six pages. These are admirable summaries, which are especially welcome in view of the importance and interest of the work which has been done in these lands and of the great volume of literature that has been epitomised. The Malay States, British Borneo, the Indian Ocean islands, and Hong Kong are treated in a chapter on the East Indies. Then come two chapters on the geology of Australia, one on New Zealand, and one on Oceania, some account being included in the last of territory acquired since the war. The last chapter, under the title of the Mandatory Regions, deals with Mesopotamia and Palestine.

In most cases the descriptions of the several regions are accompanied by sections and folding geological maps in black and white. These are printed on good paper, and students would derive considerable benefit in tinting them with washes of colour. In connection with each area a useful bibliography is also given, which, by referring readers to further sources of information, adds greatly to the value of the book.

Both author and publisher are to be congratulated upon having produced an important and most useful addition to British geological text-books.

(2) Mr. Penzer's book is of a more specialised kind. It is the second of a series devoted to the raw materials of industry, the first of which dealt with cotton and wool throughout the world. This second volume restricts itself to tin within the Empire, which, constituting two-thirds of the world's supply, provides ample material for a single volume. It is proposed to issue later another volume describing the extra-British sources of the metal.

The introduction deals with the history of tin production and with the tin-bearing minerals. Then there are four chapters describing the various fields, arranged according to continents; this part of the book contains much detailed information, and is illustrated by a number of specially drawn distribution maps. There is also a chapter on the industrial applications of tin, and one giving statistics as to output, prices, and conditions of sale. The volume closes with an elaborate classified bibliography.

A perusal of this book has left the impression that its writer has been assembling information upon a subject which is outside the limits of his own practical experience. This impression detracts a little from the authority of the work, but it must not be allowed to obscure the fact of the author's remarkable industry or of the extraordinary amount of information which he has gathered together into the 350 pages of his book. By indefatigable labour he has made a valuable compilation which many interested in the mineral industries will be glad to possess and keep by them for purposes of reference.

C. G. C.

Our Bookshelf.

The Vitamins. By Prof. H. C. Sherman and S. L. Smith. (American Chemical Society: Monograph Series.) Pp. iii+273. (New York: Chemical Catalog Co., Inc., 1922.) 4 dollars.

A VERY welcome addition to the literature of vitamins has been provided by Prof. Sherman and Mr. S. L. Smith in the volume under notice. The plan of the book is very simple; an historical introduction is followed by three chapters devoted to the three generally recognised vitamins and a final chapter is added on the relation of these important principles to the problem of food supply. A bibliography is also given, which comprises about a thousand entries and includes the literature so far as the end of 1921.

The treatment of the subject is throughout clear and critical, and the authors err if at all on the side of caution. Thus they do not regard the identity of the water-soluble and antineuritic vitamins as proved, but consider that "the preponderance of evidence thus far available favours the view that the water-soluble, growth-promoting vitamin is probably among the substances which may exert antineuritic action." They display a similarly open mind as to the vexed questions of the nature of vitamin B and its relation to the growth of yeast, which are both being actively investigated, with tantalisingly varied results, in many laboratories. The concluding chapter will probably be found the most interesting by the non-specialised reader, as in it the authors discuss the commonly used foodstuffs from a general point of view, devoting attention to their special merits or demerits, not only as carriers of vitamins but as sources of "good" or "bad" proteins and of energy. Their final conclusion brings comfort to those who are anxious as to the suitability of their everyday diet: ". . . we believe it safe to say that with a dietary selected to make the best use of our ordinary staple foods there will rarely if ever be occasion to purchase vitamins in any other form, or to give any greater anxiety to the vitamins than to some other factors which enter into our present conception of nutritive requirements and food values."

Essai philosophique sur les probabilités. Par Pierre-Simon Laplace. (Les Maîtres de la Pensée Scientifique: Collection de mémoires et ouvrages. Publiée par les soins de Maurice Solovine.) I. Pp. xii+103. II. Pp. iv+108. (Paris: Gauthier-Villars et Cie, 1921.) Each vol. 3 francs net.

OUR students spend little or no time in the study of the classical documents of scientific discovery. This neglect is very much to be regretted, for there can be

no doubt that nothing is so inspiring and fascinating as the perusal of the account of a great discovery by the discoverer himself. The personal element, so conspicuously absent in current textbooks, is in this way given its opportunity, especially if the discoverer's account is read in the original language in which it was written. The series now being issued under the editorship of M. Solovine is therefore to be welcomed.

The present essay was first printed as an introduction to Laplace's "Théorie analytique des probabilités." It gives in non-mathematical language the principles underlying Laplace's methods for dealing with the theory of probability, and shows how it is applied to problems of natural science—especially the astronomical problems to which Laplace applied his genius—to sociology and other aspects of communal life. Special attention is devoted to errors in the estimation of probabilities, due to psychological causes, and there is also a brief history of the methods of probability.

Considerable modification has since been introduced into the fundamental notion of probability, but Laplace's essay should be read by all students of mathematics. In it occurs the sentence: "Une intelligence qui pour un instant donné connaîtrait toutes les forces dont la nature est animée et la situation respective des êtres qui la composent, si d'ailleurs elle était assez vaste pour soumettre ces données à l'analyse, embrasserait dans la même formule les mouvements des plus grands corps de l'univers et ceux du plus léger atome: rien ne serait incertain pour elle, et l'avenir comme le passé serait présent à ses yeux." S. BRODETSKY.

Displacement Interferometry applied to Acoustics and to Gravitation. By Prof. Carl Barus. Pp. viii+149. Publication 310. (Washington: Smithsonian Institution of Washington, 1921.)

PROF. BARUS' work is divided into twelve chapters, and occupies an intermediate position between the usual textbook dealing with routine work and the ordinary type of original research which attacks and solves some specific and definite problem. It is throughout of an exploring nature and may be said to investigate the suitability of interferometry as a method for research in various branches of acoustics and gravitation. In the first chapter the open mercury manometer, when read by interference, is discussed. In the second, the interferometer U-tube is used as an absolute electrometer. The third deals with acoustic pressures, the fifth treats of the compression of a sound wave in a pipe, and the sixth with the vibration of a telephone plate. In the eighth and following chapters various gravitational problems are approached. The book is a storehouse of unusual experimental methods and may be consulted with advantage by any one about to commence investigations along the lines indicated.

Publications of the Washburn Observatory of the University of Wisconsin. Vol. X. Part 4: *Observations of Double Stars*, 1907–1919. By George C. Comstock. Pp. 167. (Madison, Wis.: Washburn Observatory, n.d.)

THE volume under notice forms a catalogue of all the observations of double stars made with the 16-inch refractor at Washburn Observatory by Prof. Comstock between 1907 and 1919; summaries of his earlier observations with the same instrument from 1889 to 1907 are also given, so that it is possible to detect changes. There are some 200 stars in the catalogue, including most of the well-known binaries.

The probable errors are given as $2^{\circ}{\cdot}6$, $0''{\cdot}03$ for separations less than $0''{\cdot}5$, and $0^{\circ}{\cdot}9$, $0''{\cdot}07$ for those between $2''$ and $4''$. Wires illuminated by red light were employed. This involves the possibility of small errors through unequal refraction of the images of wire and star in the eyepiece, unless the latter is achromatic. A list is given of the eyepieces, which are either Ramsden or Kellner, with powers varying from 196 to 1540; about 800 was commonly used. A. C. D. C.

Drugs in Commerce: Their Source, Preparation for the Market, and Description. By J. Humphrey. (Pitman's Common Commodities and Industries.) Pp. xi+116. (London: Sir Isaac Pitman and Sons, Ltd., n.d.) 3*s.* net.

MR. HUMPHREY has contrived to include within the moderate compass of 113 pages of text a good account of the drugs of natural origin found in commerce. The information given includes descriptions of the drugs, notes on their constituents and sources of supply, and in most cases some particulars as to their modes of preparation for the market. Great pains have evidently been taken to secure accuracy, but it should have been pointed out that the "henbane" imported from Egypt is not derived from *Hyoscyamus niger*.

The book contains six plates illustrating the more important drugs, *e.g.* cinchona, ergot, opium, and jaborandi, and six more showing scenes in drug warehouses at the London Docks and methods of packing and selecting the spices, such as nutmeg and cinnamon, used in medicine. The book can be cordially recommended to any one desirous of obtaining general information regarding this interesting and little-known group of commercial products.

Memoirs of the Geological Survey: England and Wales. The Water Supply of Cambridgeshire, Huntingdonshire, and Rutland from Underground Sources. By W. Whitaker. Pp. iv+157. (Southampton: Ordnance Survey Office; London: E. Stanford, Ltd., 1922.) 7*s.* net.

THE latest addition to the series on the underground water supplies of England deals with three counties which form a convenient unit. The counties being agricultural rather than industrial or manufacturing, very large water supplies are required in few cases. Supplies are obtained chiefly by means of wells, but some water is obtained from springs, notably the supply of the town of Wisbech, which, however, obtains its water from the county of Norfolk. At least one town of more than 5000 inhabitants seems to have no public supply. Chalk and, to a less extent, lower greensand are the sources of water in these counties. The Oolites and Lias are also of some importance. The value of chalk in this respect in the south-east of England corresponds with that of New Red sandstone in the Midlands. In addition to full details of the wells and springs in the three counties Mr. Whitaker gives some useful indications as regards enlarging and improving existing supplies.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Stature of the Scottish People.

ON the data published in the "Final Report of the Anthropometric Committee" of the British Association (1883), the Scottish people have been regarded as being considerably taller than any other British nationality. The following letter from Dr Aleš Hrdlička, of the United States National Museum, Washington, D.C., shows that, through an error in computation, the Scots have had nearly two-thirds of an inch added to their real stature.

"In preparing my report on the 'Stature of the Old Americans' I had occasion to look up, among other things, the principal records of that nature on the Scotch people. I found quite a number of these and they all showed fairly harmonious results, with one exception. This was the record on the Scotchmen in the 'Final Report of the Anthropometric Committee' of the B.A.A.S., 1883, p. 256. This record gave results that were so much higher than any others that I was finally led to a re-computation of the series. Taking the number of persons measured and the record in inches, in which the measurements were originally recorded, I found to my surprise a different and a very perceptibly lower average. The averages given in the Report were 68·71 in. or 174·6 cm., while I obtained 68·1 in. or 172·97 cm.

"I should be thankful to you if you would bring this matter to the attention of the members of the Anthropological Institute, and have it looked into, and if it should be found that an error has been made, then I think it would be advisable for some one to publish a little note on the subject, for the figures of the Anthropometric Committee have been widely utilised (see Deniker, Martin, etc.)"

I have not checked Dr Hrdlička's estimates, but I have no doubt that they are right. The average stature of the four British nationalities thus amended reads: Scottish, 172·9 cm; Irish, 172·6 cm; English, 171·2 cm; Welsh, 169·4 cm.

ARTHUR KEITH.

Advanced Mathematical Study and Research at Cambridge.

IT has been suggested to me that attention might well be directed through the columns of NATURE to a point in the regulations of the University of Cambridge which prevents many graduates of other universities taking advantage of the opportunities Cambridge offers for advanced mathematical study.

In most universities other than Cambridge our best students of mathematics now usually read for a degree in science. They have passed an entrance examination of a standard far higher, I need scarcely say, than that of the Previous Examination. But neither in their entrance examination nor in their course need they have taken Latin or Greek. They are thus cut off from the privileges of affiliation, which include exemption from the Previous Examination and permission to take their degree on Part II. of the Tripos after a residence of two years.

It is true that graduates of other universities may proceed to the degrees of M.Sc. and Ph.D. at Cambridge by research, without any questions being asked as to the nature of their entrance examination. But in my opinion, at least, few of the graduates of the Scotch universities, the newer English universities, and the universities of the Dominions are ready to devote themselves to research in mathematics immediately after graduation. What they want at that stage is just such advanced instruction as Cambridge now offers in the subjects of Schedule B of Part II. of the Tripos. They should be able to take the Part II. examination easily after six terms. Before the end of that time they may have begun some research. But the man who wishes to become a professional mathematician should continue research work for at least two years after taking Part II. Some of the time would be spent at Cambridge; and one or other of the great schools of mathematics at Paris, Rome, Berlin, or Gottingen should certainly be visited.

Oxford admits to the status of Senior Student any person who has obtained a degree at an approved university after a three-year course, the degree also having been approved by the Hebdomadal Council. If Cambridge would modify its regulations for admission to the privileges of affiliation so that our best graduates in mathematics could take the Cambridge B.A. on Part II. after six terms, I believe its school of mathematics would receive a larger number of brilliant scholars, and there would be more of our mathematicians at home and abroad engaged in research.

H. S. CARSLAW.

The University, Sydney, May 1.

Condition of Electrolytes in the Blood.

ARE the salts present in the blood ionised to an equal extent as similar concentrations of these salts in aqueous solution? Are the ions absorbed by the protein? These are questions that have been attracting the attention of physiologists and biological chemists. Investigators have attempted to answer these questions principally by two methods—compensatory dialysis of the serum (Rona, Michealis, and their co-workers) or filtration with pressure (Starling, Cushny, Richter-Quittner).

It seemed worth while to determine the concentrations of other ions by electromotive force measurements, as is done in the case of the hydrogen-ion. Accordingly, a 0·2 per cent. sodium amalgam that is but slowly decomposed was used as a sodium electrode. After measuring the E.M.F. of this electrode against known concentrations of sodium chloride of known degree of ionisation, the normal potential of this amalgam electrode was obtained. The E.M.F. of samples of serum and plasma were then measured. When from these readings the total concentrations of Na present were recalculated on the basis that the degree of ionisation of the sodium salts was the same as in an aqueous solution, the calculated Na concentration and that found by analysis were in very good agreement. For example in two samples the calculated values of sodium were 3·51 and 3·67 grams; the values found were 3·46 and 3·65 grams per litre. Thus the conclusions of the aforementioned workers that Na is not bound in the serum, because it can be dialysed and filtered *in toto*, has been confirmed.

To determine the concentration of Cl-ions, an Ag/AgCl electrode was used. By calculations similar to those outlined in the case of sodium, it was found that the quantities of Cl present calculated from E.M.F. measurements of serum and plasma, on the assumption that we were dealing with an aqueous

solution of sodium chloride, were in good agreement with those found by analysis. Thus in two samples, for example, the totals for chlorine calculated as NaCl were 6·443 and 6·541; the totals found were 6·535 and 6·61 grams. Chlorine likewise is apparently as free as in an aqueous solution.

The writer is at present developing a calcium electrode to determine the state of calcium in the blood.

BENJAMIN S. NEUHAUSEN.

Johns Hopkins University, Baltimore, Maryland.

The Dimensions of Area.

IN my "Physics," pp. 423-426, it is maintained that it is incorrect to attribute to area (or volume) the dimensions L^2 (or L^3); but no example of an error arising from such attribution could be given. It has since occurred to me that an excellent and important example is provided by Child's high vacuum current law, according to which σ, the current density, is proportional to $\left(\frac{e}{m}\right)^{\frac{1}{2}}\frac{V^{\frac{3}{2}}}{l^2}$.

The laws assumed in the deduction of this relation are (1) $\frac{V}{l} . A = \alpha . e$ (Poisson's equation), (2) $\sigma . l . A = \beta . e . v$, (3) $m . v^2 = \gamma . e . V$, where A and v are area and velocity, and α, β, γ formal constants or no-dimensional magnitudes. If in place of A we write l^2, we find that $\sigma^2 l^3 m \left(\frac{l}{e}\right)^n V^{n-4}$ is no-dimensional for all values of n. The solution is ambiguous and the Child relation is not deducible by dimensional argument, as it clearly ought to be. If, on the other hand, we retain A, $\sigma^2 l^4 \left(\frac{m}{e}\right) V^{-3}$ is the only no-dimensional magnitude independent of A and v, we obtain a unique and correct result.

The removal of the ambiguity must be due to the introduction of some additional law. This additional law is that the ratio of the area in (1) to the area in (2) is independent of l, or that l is perpendicular to A in both cases, or that the electrons follow the lines of force. If we omit the important magnitude shape in stating the dimensions of A, this law cannot be introduced into the dimensional argument, because there remains no magnitude to measure direction.

The additional law is not quite strictly true because of the inertia of the electrons. It follows, therefore, that if the electrodes are arranged so that the curvature of the lines of force is very great, small departures from the Child relation are to be anticipated. But so long as the curvature is small, the relation will hold if the systems compared are geometrically similar, differing only in their size l. So far as I know, the relation has hitherto been proved only for parallel plane and concentric cylindrical electrodes; experimentally it is known to be true over a much wider range.

NORMAN R. CAMPBELL.

19 Holland Park, W.11, June 4.

The Resonance Theory of Hearing.

MR. ACKERMANN (NATURE, May 20, p. 649) is probably correct when he states that the first incoming sound wave sets all the resonators of the ear temporarily in vibration, and also, that as the sound waves continue the vibrating resonators decrease in number until only those are left in motion that are executing either sympathetic or forced vibration in time with the incoming sound waves. But surely he has left out of account the probable amplitude of the motion performed by the resonators, and the probable physiological properties of the mechanism, when he judges the intensity of the sound stimuli sent along the auditory nerve to the brain to be directly proportional to the number of resonators that are swinging at any moment?

At the present time we have practically no information concerning the type of response given by the auditory nerve. It may, like certain motor nerve fibres, obey the all-or-nothing law, or it may conduct with a decrement, or it may be graded in its response. But in all these cases the amplitude will be an important factor in deciding the response given by any one hair cell and nerve fibre. But there are, I think, other physiological factors which Mr. Ackermann has overlooked. For although we cannot directly stimulate the hair cells of the cochlea electrically and ascertain the approximate relationship between strength of stimulus and strength of response, so that we can demonstrate clearly that the auditory mechanisms have such physiological properties as threshold, latent period, simultaneous and successive contrast (as we can, for example, in the case of the skin end organs), yet we have sufficient evidence that these properties are exhibited also by the auditory mechanism as by the other organs of special sense. Reconsidering now the case that Mr. Ackermann has taken, and assuming as a basis for calculation—

(a) that the sound wave energy entering the ear in unit time is constant,

(b) that the pitch is constant,

(c) that the mean amplitude of all the resonators in vibration at any one time is inversely proportional to the number in vibration; and

(d) that the energy available for distribution is proportional to the length of time during which the sound waves have been arriving, i.e. that none of the energy entering the cochlea has been lost in eddies, friction, etc.;

the following table shows the number of oscillators in vibration and their mean amplitude:

No. of Sound Waves from Common Cement	No. of Resonators in Vibration	Mean Amplitude.
1	6000	·003
2	1000	·03
3	600	·08
4	450	·13
5	350	·21
6	290	·31
7	240	·44
8	200	·60
9	170	·80
10	150	1·00

It will be seen that after one sound wave 6000 resonators are in vibration with an amplitude of 0·003, whereas after 10 sound waves 150 resonators only are swinging with an amplitude of 1. The table shows that there is a rapid increase in the mean amplitude of the vibrating resonators at the commencement of a tone.

There is no pretence of any exactness in the above values. They merely illustrate the kind of results to be expected. It should be noted further that at any instant those resonators approximately "in tune" with the incoming sound waves will have amplitudes considerably greater than the mean value, others nearest to those which are coming to rest will have amplitudes less than the mean value.

Therefore, even after one complete sound wave there will be already a clearly marked selection of the "in-tune" group of resonators.

Taking now the physiological effects into consideration, the threshold factor will definitely rule out all amplitudes below a certain value, so that after a certain number of sound waves have entered the ear the amplitude of the "in-tune" resonators will be the first to rise above the threshold and will cause impulses to pass up the auditory nerve. A little later a larger number of resonators will have reached amplitudes above the threshold, so that there should be a gradual increase in the number of resonators in active response, until the full steady value is reached. Calculation shows that the "in-tune" resonator should attain 90 per cent. of its final amplitude in eight vibrations. On the resonance theory one would therefore expect a gradual rise in the sound intensity occurring in a time interval of the order of 10-20 vibrations of the incoming sound waves (*i.e.* 1/25-1/12 sec. for middle C), and not a fall as Mr. Ackermann has suggested in his letter. It would seem that this effect is responsible for the absence of roughness at the commencement of a tone due to the imperception of the transient vibrations of "out-of-tune" resonators.

Now if the rise of sound intensity is a gradual one, what, it may be asked, is the mode of perception of a tone which starts with large amplitude and gradually diminishes as it goes on—*e.g.* a piano note? In such a case it would seem that after a very few vibrations, the swings of the resonators must reach such an amplitude that their motion is perceived. In this case, then, the vibration of "out-of-tune" resonators makes itself perceived because the auditory nerve fibres are taking up responses before there have been sufficient incoming sound waves to damp out the "out-of-tune" resonators. It would seem to be this effect which gives the transient harshness to the commencement of a piano note, causing it to sound to the ear as if it started with a consonant.

H. HARTRIDGE

King's College, Cambridge.

An Experimental Towing-tank used by Benjamin Franklin.

IN the "Calendar of Industrial Pioneers" in NATURE, May 6, p. 598, relative to the anniversary of William Froude, your correspondent says: "His (Froude) work led to the construction by the Admiralty of the experimental tank at Torquay, the first of its kind ever built."

It will be doubtless interesting to readers of NATURE to have it brought to their attention that Benjamin Franklin in his many and varied investigations in philosophical subjects investigated, to some extent, the difference of navigation in shoal and deep water. In a letter written to Dr. John Pringle, May 10, 1768, he gives the results of experiments made along these lines. The letter tells of how, during a trip with Dr. Pringle in Holland, it was brought to their attention that the *treckschuyt* in one of its trips went slower than usual, due, as the boatmen explained, to the water in the canal being low. After his return to England, not being entirely satisfied with the boatman's explanation, Franklin questioned the Thames river watermen and found them all agreeing as to fact, but differing widely in expressing the quantity of the difference. He, therefore, designed the following experiment, which in its nature is a forerunner of the modern towing-tank. I quote from his letter:

"I provided a trough of planed boards fourteen feet long, six inches wide, and six inches deep in the clear, filled with water within half an inch of the edge, to represent a canal. I had a loose board, of nearly the same length and breadth, that, being put into the water, might be sunk to any depth, and fixed by little wedges where I would choose to have it stay, in order to make different depths of water, leaving the surface at the same height with regard to the sides of the trough. I had a little boat in form of a lighter or boat of burden, six inches long, two inches and a quarter wide, and one inch and a quarter deep. When swimming, it drew one inch water. To give motion to the boat, I fixed one end of a long silk thread to its bow, just even with the water's edge; the other end passed over a well-made brass pulley of about an inch diameter, turning freely on a small axis; and a shilling was the weight. Then, placing the boat at one end of the trough, the weight would draw it through the water to the other.

'Not having a watch that shows seconds, in order to measure the time taken up by the boat in passing from end to end, I counted as fast as I could count to ten repeatedly, keeping an account of the number of tens on my fingers. And as much as possible to correct any little inequalities in my counting, I repeated the experiment a number of times at each depth of water, that I might take the medium. And the following are the results:

	Water $1\frac{1}{2}$ inches deep.	2 inches.	$4\frac{1}{2}$ inches.

An Experimental Confirmation of the Kinetic and Molecular Theories of Magnetism.

CURIE'S law states that ferromagnetics above the critical temperature behave in such a way that the susceptibility (k) is inversely proportional to the absolute temperature (T), in short, that the product $k \cdot T$ is a constant. The physical meaning of this law is that when the molecular magnets have complete freedom of rotational movements, the energy of magnetisation is then only opposed by the energy of thermal agitation and, consequently, any given state is a state of equilibrium.

Below the critical temperature complications introduced by the mutual magnetic actions of the molecules, one on the other, and by the approach to a saturation limit have obscured any such simple law. It is, however, possible to eliminate, or allow for, the effects of these disturbing factors and to make experiments, under hysteresis-free conditions, upon the variation of susceptibility with temperature. Experiments of this kind have been carried out on

iron and nickel, and the reduction of the observations has now been completed, with the result that the Curie law, with certain limitations, is found to apply to the ferromagnetic state, and the relation $\kappa . T =$ a constant is approximately satisfied, but the constant now is of a very different magnitude from the former one. There is, however, this simple and important relation between the constants in the two states—their ratio is *the kinetic energy per unit of temperature per gram of two degrees of freedom*, and is thus immediately connected with the gas constant R. This result is of importance because it shows that the change from the ferromagnetic to the paramagnetic state is quantitatively explicable as due to the acquisition of the kinetic energy per unit temperature required for the two degrees of rotational freedom which are effective in controlling magnetic susceptibility.

Thus there is proof from magnetic data alone, independently of thermal data, that the change at the critical temperature from ferro- to paramagnetism is due to the gain of energy associated with two degrees of freedom.

This acquisition of energy-content makes itself evident in the increase of specific heat which ferromagnetics show at and above the critical temperature, and is quantitatively in agreement with the magnetic result.

It is no longer necessary now to assume, as has been done, that an immense intrinsic *magnetic* field is the cause of ferromagnetism, although it may be convenient to introduce a fictitious magnetic field such that it will give rise to energy effects equivalent to the energy of two degrees of freedom.

The results which have been discussed above are also a confirmation of the simple view advanced by Ewing in his earlier papers on the molecular theory of magnetism, in which he suggests that the loss of ferromagnetic qualities may be caused by the oscillations of the molecular magnets which become wider and wider up to the critical temperature, at which point they pass from vibration to rotation.

May 30.

Molecular Ælotropy in Liquids.

A VERY remarkable feature shown by many liquids in experiments on the molecular scattering of light is that the scattered beam in a direction transverse to the primary rays shows a large admixture of *unpolarised* light, the proportion of this to polarised light in the scattered beam being several times greater than in the case of the same substance in the condition of vapour at atmospheric pressure. This fact seemed at first very puzzling, an explanation is, however, now forthcoming. A theory of the phenomenon has been worked out by the writer which not only explains the facts in a simple and quantitative manner, but has also pointed out the way to further fruitful research. It may be briefly indicated as follows:

The polarised and unpolarised parts of molecularly scattered light may be conceived as arising in two distinct ways; the former is a *mass-effect* arising from the thermal fluctuations of density in the fluid, and its magnitude is given by the Einstein-Smoluchowski formula

$$\frac{\pi^2}{18} \cdot \frac{RT\beta}{N\lambda^4} \cdot (\mu^2 - 1)^2(\mu^2 + 2)^2,$$

and as we pass from the condition of vapour to that of liquid in which the molecules are more closely packed together, it increases much less than in proportion to the increased density. The *unpolarised* part of the scattered light is, on the other hand, a *molecular* effect, and its magnitude increases simply in proportion to the number of molecules per unit volume. The ratio of unpolarised to polarised part of the scattered light should therefore be considerably enhanced. This is exactly what is observed. If I_1 and $2I_2$ are respectively the polarised and unpolarised parts of the transversely scattered light, the ratio $I_2/(I_1+I_2)$ may be determined experimentally by analysis with the aid of a double-image prism and a nicol. The Table below shows in the second column the value of this ratio as determined by Lord Rayleigh for certain substances in the state of vapour, in the third column the value of the ratio for the liquid state at ordinary temperature as calculated from the writer's theory, and in the fourth column the value as determined by Mr. K. Seshagiri Rao in the present writer's laboratory. The agreement is significant.

RATIO OF COMPONENTS OF POLARISATION

Substance	Observed, Vapour	Calculated, Liquid.	Observed, Liquid.
	Per cent.	Per cent.	Per cent.
Ethyl Ether	1·7	10·9	8·2
Benzene	6·0	39·8	39·8
Chloroform	3·0	18·2	15·5

We may also view the matter in another way. When a substance is in the state of vapour under small pressures, both the positions and orientations of its molecules are absolutely at random, and assuming the molecules to be ælotropic, the degree of imperfection of polarisation of the light scattered by it may easily be calculated, as has been done by the late Lord Rayleigh. On the other hand, in the liquid state, the packing of the molecules is so close that their ordering in space is no longer at random; but we may still, at least in the case of ordinary liquids, consider the orientations to be arbitrary without serious error. If we take this into account in determining the resultant effect of the waves scattered by the individual molecules, we should be led to the same result as has been indicated above.

The theory put forward has other notable successes to its credit. The Einstein-Smoluchowski formula indicates that though the density of a liquid diminishes with rise of temperature, its scattering power should increase and become very large as the critical temperature is approached. Similarly, as the temperature is increased, the scattering power of the saturated vapour should increase much more rapidly than in proportion to its density. Accordingly, in both cases, we should expect the polarisation of the scattered light to improve steadily with rise of temperature and become practically complete as the critical temperature of the liquid is approached. Experiments with benzene liquid and vapour made by Mr. K. R. Ramanathan have quantitatively confirmed this prediction. A similar improvement in polarisation has also been observed by Mr. V. S. Tamma in experiments on the scattering of light in *binary liquid mixtures* as the critical temperature for separation into two phases is approached.

Recent Investigations of the Lake Dwellings of Switzerland.

By Prof. EUGÈNE PITTARD, University of Geneva.

AS a result of the persistent drought at the beginning of 1921, the level of the Swiss lakes fell considerably, and hitherto-unsuspected depths were brought to light. This phenomenon was particularly marked in the three lakes of Neuchâtel, Bienne, and Morat, in which important areas had already been laid bare by the regulation of the waters of the Jura. Long stretches of beach which, until that time, had not been accessible to the inhabitants of the shore, completely modified the aspect of these lakes.

During the early months of 1921, in those districts in which the men of the polished stone age had built their dwellings, a large number of piles gradually emerged which the present generation had seen only under several feet of water. It was a revocation of vanished ages which appealed to the emotions. It enabled the imagination to reconstruct more readily a picture of those who, thousands of years ago, were the authors of the greatest of social changes when they introduced the cultivation of cereals, the domestication of animals, and the like. From day to day more and more of the substructure of these cities of the lake was uncovered, and from all parts travellers came to look upon this impressive spectacle, which perhaps we shall never see again.

FIG. 1.—Part of the site at Greng, Lake of Morat.

It will be readily understood that such exceptional conditions encouraged Swiss men of science to undertake fresh investigations on several of the lacustrine sites.

The numerous finds which have been made since 1854 in all the lakes which were at one time inhabited by men of the stone age and the bronze age have enabled us to reconstruct, in great part, the material culture of these ancient populations. We have obtained, to some extent, an insight into their mode of life; we can frame hypotheses as to their race; but there are still many problems which require elucidation. I will indicate here a few of these problems which relate to the neolithic period.

1. We do not yet know with certainty to which ethnological group to assign the builders of the lake dwellings and their successors up to the end of the bronze age. It has been held, on the evidence of bones recovered from among the piles, that this type of habitation was invented or introduced by brachycephals—until that time unknown in Western Europe. Further, that this race held its own on the Swiss lakes until the end of the neolithic age, when dolichocephals begin to appear in the lake-dwelling sites, coming, perhaps, from the north. (Their ethnical affinities also are still to be determined. Will our hypotheses stand?)

2. The dispositions of lake-dwelling sites, their town planning, if one may use the phrase, is, in essentials, unknown. Even the extent of the ground they covered in many cases has not been determined exactly.

What exactly was the topographical plan of each site? Were the sites, that is, those of the same epoch and situated on the same lake, arranged on a specific plan, identical throughout, or was a free rein given to the fancy of the builders in each case? In other words, was there a type of lake village, and, if so, what was it? Was the lacustrine city an organic whole, with the houses grouped on one frontage, or was it composed of a series of small islands, and, in that case, what were the dimensions and dispositions

of these islands? Did they communicate with one another by bridges or by navigable canals? If so, what were the measurements and arrangement of these bridges or canals?

What was the form of the dwellings? Those authors who have attempted to reconstruct groups of lake dwellings have differed remarkably in their attempts. These diversities show how little solid basis there is for our knowledge in this matter, notwithstanding the evidence from sites such as Schüssenried, Robenhausen, Niederwil, etc. Was the settlement protected against the waves caused by prevailing winds by some projecting construction—it may be assumed, a stockade of piles?

3. Do the most important of the articles in daily use by the inhabitants of the lake dwellings in the neolithic period date from the beginning of lake settlements? Were the various types of objects which are exhibited in the cases of our museums invented at different ages in accordance with the growth of needs, or were they in use in the earliest period? This question can be settled finally only by stratigraphical study.

4. Were the five domesticated animals of the neolithic period (the ox, the dog, the pig, the goat, and the sheep) present in the earliest period of the lake dwellings, or may we accept the suggestions put forward by various authors that these domestic animals were introduced gradually during the age of polished stone?

These are a few of the questions which still await an answer, notwithstanding the numerous investigations which have been undertaken since the memorable winter of 1853–54. The solution of these problems is naturally very difficult owing to the nature of the ground upon which investigations have to be carried out. It is not easy to make stratigraphical observations on sites which are always submerged. The diving bell alone can be used. It is for this reason that the persistent drought at the beginning of the year 1921 has proved so favourable to research.

Let us now consider the results which were obtained in the course of recent investigation.

Very few human skeletal remains of neolithic age were found; but an important discovery was made at St. Aubin. In the lowest stratum of this site, which is the oldest of the Swiss neolithic lake-dwellings, M Vouga found a human cranium, which was sent to me. It is unquestionably dolichocephalic. This is the first piece of definite evidence of this character. Does it affect previous hypotheses as to the race of the builders of the lake-dwellings? I do not think on such slender evidence we can maintain that it does. The skull in question is feminine, from which fact we may conclude that it belonged to an inhabitant of the site at St. Aubin and not to a foreigner, whose head might perhaps have been brought home as a trophy of war. The discovery, however, is of importance, because it was made in the course of investigations on stratigraphical lines. It is not a skull unearthed at hazard from the mud or sand. It was *in situ*.

In the course of the spring and the summer of 1921, two detailed topographical surveys were made—one, at my suggestion, at Greng in the Lake of Morat (Figs. 1 and 2) by MM. Le Royer and Winkler, the other on the foreshore of Geneva. This is the first time that any work of this character has been undertaken in Switzerland. The station at Greng was not completely surveyed. A record was made of the position of those piles only which were left uncovered by the fall of the lake and of those which were in shallow water. At Geneva, work of considerable extent was undertaken

FIG. 2.—Part of the Neolithic site at Greng, Lake of Morat.

by MM. Le Royer and Blondel. It has recently been completed (April 1922). Among the conclusions which emerge, it is now clear that the inhabitants of the lake-dwellings in the polished stone age had constructed stockades facing the open water, for protection against the waves raised by the prevailing northerly wind. These breakwaters must have afforded the dwellings relatively smooth water. From these investigations it may also be concluded that the lake-dwelling sites of Geneva were of considerable size. Unfortunately of these there remain to-day only some thousands of piles implanted in the bed of the lake.

Geneva is thus one of the most ancient cities of the world, since man has lived on this site continuously ever since the neolithic period.

The stratigraphical investigations undertaken by M. Vouga enable us to establish with certainty the succession of the types of industrial objects throughout the neolithic period of the lake-dwellings. Several of our *a priori* conceptions based on typology must be abandoned. Thus the pottery of the earliest period is more refined, more beautiful, more highly burnished than that of later periods. In technique it approaches more nearly the pottery of the bronze age than that of the middle and upper neolithic.

Thanks to a careful study of the stratification of objects found at Auvernier, M. Vouga has been able to plot out the progressive modification of several objects in daily use, such as the axe-hafting sockets of stag horn, flint arrow-heads, and the like.[1]

In many cases, however, stratigraphical study has only slightly modified classifications, such as those of Ischer, based upon the typology of lake-dwelling sites which have been investigated with minute care.

Other observations of importance for the history of culture have also been made by M. Vouga:--

The lowest stratum (IV.) has not yet yielded any of the spindle whorls which are necessary for weaving. The art of drilling stone would appear to begin in Stratum III., but only in the triangular axe hammer-head. The true perforated axe hammer-head appears much later—in Stratum I.

In Stratum I.—the latest—appear flint flakes of Grand-Pressigny type. Relations between Switzerland and western France are thus clearly established.

For the first time *all* bones found in the excavation of a lake-dwelling site have been preserved. My assistant, Dr. Reverdin, and myself have examined more than 4000 mammalian bones from the station of St. Aubin. Our conclusions, which are valid only in respect of the material obtained and for this site, may be summarised as follows:—In the neolithic period corresponding with the earliest lacustrine sites, the horse was not domesticated. It was not even hunted, or, if it was an object of the chase, its flesh was not brought back to the lake-dwelling. If this were the case, would it not be permissible to suggest a taboo as the reason? The five domesticated animals of the neolithic period were represented in the lake-dwellings from the earliest times. Accordingly, the suggestion that domestic animals appear at different stages cannot be accepted. It is true that these five animals are not represented in equal abundance. At the beginning of the period of domestication, the goat and the sheep are much more rare than the ox, the dog, and the pig.

For a considerable time man continued to rely for his food-supply on wild animals, especially the stag; but the proportion of domestic animals rapidly becomes preponderant.

As regards their culinary tastes, the neolithic lake-dwellers seem to show a preference for certain of the domestic animals. The species of which they ate most abundantly were the ox and the pig; next come the dog (though it is not certain that the dog was eaten), the sheep, and the goat. What is the reason for this order of preference? Does it depend upon a special taste for any particular meat? Would they not in that case rear in large numbers only those species which they appreciated most?

The lake-dwellers in the stone age ate the domestic animals when they were full grown, except in the case of the pig. This animal was frequently eaten while it was young, and even when it was still a sucking pig. The ox and the goat were never eaten when quite young. The distinction was dictated, without doubt, by the desire to use the milk-giving qualities of the cow and the goat, and also, perhaps, the sheep, as long as possible, but this explanation does not affect the males of these species.

It thus appears that the exceptionally low water in the Swiss lakes in 1921 has not been without interest to science. Thanks to this phenomenon, some new and important facts have been recorded in the history of the culture of the neolithic lake-dwellers and, at the same time, of all the neolithic peoples.

[1] I would refer the reader to the reports published by M Vouga in "Indications d'Antiquités suisses" in the *Arch. suisses d'Anthrop Gén*, Geneva, 1921 and 1922.

Vitamin Problems.[1]

By Prof. A. Harden, F.R.S.

THE existence of three vitamins, termed A, B, and C, has now been firmly established and a general idea has been obtained of their distribution among animal and vegetable organisms. Hitherto, comparatively little quantitative work has been done in this direction, and further progress must depend on a more general adoption of quantitative methods. These are at present tedious and not very accurate. In the case of each of the vitamins the requirements of the special animal employed serve as the unit of comparison and these vary considerably from individual to individual, so that many observations are necessary if any, even moderate, degree of accuracy is to be attained. Thus in the estimation of the antiscorbutic potency of food materials, by the method worked out by Miss Chick and her colleagues at the Lister Institute, it has seldom been possible to achieve a greater accuracy than about 25-50 per cent. This obviously imposes a very serious limitation on any attempts to study variations in potency unless these are of a very gross order. Another great difficulty inherent in this kind of observation is that when the

[1] Abridged from a Discourse delivered at the Royal Institution on Friday, April 28.

potency is low, the necessary dose of the material to be tested is correspondingly high, and soon transcends what is permissible without interference with other necessary conditions of the diet, such as protein content, etc. Very much the same conditions hold with regard to Vitamin B, especially when this is estimated by the effect of the material on the growth of rats; and, as a matter of fact, the great bulk of the work carried out in America by this method is not strictly quantitative, but simply leads to the result that a certain ration does, or does not, suffice for the growth of a young rat.

As regards Vitamin A the method of Zilva and Miura promises to yield moderately accurate and consistent results. This is attained by keeping the experimental animals (young rats) on a diet totally deficient in Vitamin A until they have ceased to grow, and then ascertaining the minimum dose of the material to be tested which will induce definite and steady growth for four weeks. Animals which do not cease to grow in three weeks are rejected, greater uniformity in the results being thus attained. The test material is, whenever possible, administered quantitatively to the animal and not, as was formerly the practice, mixed with the ration in a known proportion. One of the immediate results of the application of this method has been the discovery that cod-liver oil, formerly classed with butter as a good source of Vitamin A, is in reality 200-250 times as potent as butter and is, along with similar fish-liver oils, by far the richest in this material of all the substances which have so far been examined.

A further piece of information, which is essential for the detailed study of these substances, is their behaviour towards heat, oxidation, etc. In this respect some progress has been made, and it may be stated with some confidence that both Vitamins A and C are moderately stable towards rise of temperature, provided that air be excluded, whereas in the presence of air they are rapidly inactivated. Whether the effect of air is reversible or not has not yet been ascertained. Vitamin B, on the other hand, appears not to be affected by air and is also moderately stable towards rise of temperature. None of the three vitamins is easily inactivated by hydrolysis under anaerobic conditions, and this fact has led to the interesting observation that Vitamin A, although usually associated, in the animal organism, with fat, is not itself a fat but remains in the unsaponifiable residue with almost unabated potency. This indicates how small a weight of the vitamin itself is necessary for the daily ration of a young rat. In some cases as little as 1·5 milligram of the oil is sufficient to permit of definite growth, and of this only 1-2 per cent. is unsaponifiable, while, as is well known, the chief constituent of the unsaponifiable matter is cholesterol, which has itself no vitaminic potency. The actual requirement of the vitamin itself must therefore be of the order of 1/500 milligram per diem. The other two vitamins have not been obtained in so concentrated a form, but it appears highly probable that they too are present in foodstuffs only in infinitesimal amounts.

The origin of all three vitamins is to be sought in the vegetable kingdom. The production of Vitamin A has been followed (Coward and Drummond) from the seed, and it has been found that it does not appear until the photosynthetic processes begin. Thus sunflower seeds are almost devoid of it, and so are the etiolated seedlings formed when these seeds germinate in the dark. In the light, on the other hand, the green seedlings, grown in a medium free from the vitamin, produce it freely. This vitamin is often closely associated with the carotene and xanthophyll of plants; so intimately, indeed, that it was at one time thought that it might be closely related to, if not identical with, one of them. The association, however, although very frequent, is not essential, and no definite relation can be shown to exist between the two. Vitamin C is either absent from seeds or only present in them in very minute amount, but appears when the seed germinates and before any green parts are formed. Nothing is, however, known of the inactive pro-vitamin or of the process by which it is rendered active.

Concerning the origin of Vitamin B a considerable amount of discussion has taken place. Its presence in a large proportion in yeast points to the probability that it can be produced without the intervention of light, and both in America and in this country it has been found that yeast can actually produce the vitamin when grown in a "synthetic medium" comprising only substances of known composition and free from the vitamin in question. Recently, however, Eijkman, in Holland, has obtained a contrary result, so that this question remains at the moment open.

The animal organism appears to be unable, in normal circumstances, to produce any of these principles for itself, and hence the amounts found in animal products depend ultimately on the diet of the animal. This opens up, among many other problems, the important question of the vitaminic properties of milk, and there seems to be no doubt, from experimental work, both here and in America, that these properties are profoundly affected by the diet of the cow. Milk obtained in winter when the animals are stall-fed has been shown to be markedly deficient in Vitamin A, and there is also great danger of a deficiency of Vitamin C. One of the pressing requirements of the moment is the careful quantitative examination of foodstuffs available for the feeding of cattle, so that a rational system of winter feeding can be adopted which will produce milk as good as that given in summer. Such an examination would seem naturally to fall within the purview of the Board of Agriculture.

The evil results of a deficiency of Vitamins B and C, especially in the diet of children, are well known—beri-beri and scurvy, latent or patent—but the effect of a lack of Vitamin A is not so well recognised or so universally acknowledged. One school considers that a deficiency of this vitamin is at least a prominent factor in the causation, if not, as they formerly held, the sole cause of rickets. Others consider rickets to be a disease brought on by non-hygienic surroundings, lack of fresh air and exercise, etc. The latest experimental results show that rickets (in rats) can infallibly be produced by dietetic changes, but that the lack of Vitamin A does not of itself lead to the disease unless at the same time the diet is faulty as regards the supply of calcium or phosphorus. This faulty mineral supply

does not usually lead to true rickets if sufficient Vitamin A be present, although the bone formation under these circumstances is not quite normal. This explains the well-known curative effect of cod-liver oil in rickets. So marked is the effect of this remedy, that McCollum, not appreciating the relatively enormous concentration of Vitamin A present in it compared with that in butter, as proved by Zilva, has suggested that cod-liver oil contains some other specific substance absent from butter, to which its great superiority is due. The difference, however, seems to be merely quantitative, and the further complication suggested by McCollum appears to be unnecessary.

These experiments on rickets have led to what promises to be a discovery of far-reaching importance. Rats on a diet, which in the laboratory will infallibly produce rickets, do not acquire the disease if they are exposed to sunlight in the open air or to ultra-violet radiation, and rats which have acquired the disease can be cured by either of these treatments, just as they can be cured by the administration of cod-liver oil. Sunlight and ultra-violet radiation have also been found to be effective cures or preventives of rickets in children. The cures by light and by cod-liver oil seem to proceed in precisely the same way, and the idea naturally suggests itself, especially to the mind of a chemist, that the light actually brings about the synthesis of the Vitamin in the animal body just as it does in the plant. This idea still awaits experimental verification or disproof; but there is no doubt that the discovery of this function of light will lead to profoundly important developments in our knowledge.

Obituary.

Prof. W. Gowland, F.R.S.

PROF. WILLIAM GOWLAND died on June 10 in his eightieth year. He had originally intended to enter the medical profession and actually worked with a medical man in Sheffield for two or three years. Afterwards he became a student at the Royal College of Chemistry, from which he passed in 1868 to the Royal School of Mines. Two years later he obtained the associateship both in mining and metallurgy. He was awarded the Murchison medal in geology and the De la Beche medal in mining.

His first post was that of chemist and metallurgist to the Broughton Copper Company, Manchester. Two years later he went out to the Imperial Mint at Osaka, Japan, and held the post of chemist and metallurgist there for six years. During the next eleven years he acted as assayer, metallurgist, and chief of the foreign staff at Osaka, and was for some time adviser to the Imperial Arsenal. His work was of a decidedly varied nature, and he did much to introduce Western metallurgical and chemical methods into the departments with which he was associated. It was during this period that he acquired the knowledge of Japanese methods of extracting, refining, and working metals for which he afterwards became so famous. He carried out exploration work in Korea on behalf of the Japanese Government, in the course of which his expedition had some lively skirmishes with the natives.

As a young man Prof. Gowland was a keen oarsman, and was the first to introduce rowing into Japan. He had two modern "eights" built to encourage boat-racing among the staff of the mint, but they found these craft too unstable for their liking. Eventually they decided to choose their own boats and presented two for his inspection. He found they had selected a pair of "cutters" and had fitted each with port and starboard lights. He was also the first to initiate the Japanese into the use of the wheelbarrow. He had occasion to do this in connexion with some excavation work in the copper mint, and provided the labourers with barrows. The next morning he was astonished to find that the wheels had been removed and the sturdy Japanese were carrying the loaded wheelbarrows. On leaving Japan in 1889, the order of "Chevalier of the Imperial Order of the Rising Sun" was conferred on him personally by H.I.M. the Emperor of Japan. During his residence there he gradually built up a very fine Japanese art collection, which included some valuable kakemonas.

Returning to England, Prof. Gowland acted as chief metallurgist to the Broughton Copper Company for some years, and in 1902 was appointed professor of metallurgy at the Royal School of Mines, in succession to the late Sir William Roberts-Austen. This post he held for seven years and retired in 1909.

So far as metallurgy is concerned, his chief interest lay in the non-ferrous metals, principally copper, silver, gold, lead, and their alloys. His knowledge, in particular, of the metallurgy of copper was unique, based as it was upon experience of the best methods in vogue, both in the East and West. In 1914 he published a textbook on the metallurgy of the non-ferrous metals which quickly became recognised as an authoritative work on the subject, and is now in its third edition. He also contributed various papers to the Institution of Mining and Metallurgy, the Chemical Society, and the Society of Chemical Industry. He was an original member of the Institute of Metals, its third president, and its first May lecturer. In 1907 he was elected president of the Institution of Mining and Metallurgy, and in 1909 was awarded the institution's gold medal.

There was, however, another side to his intellectual interests, as shown by his membership of the Society of Antiquaries, the Royal Anthropological Institute, and the Numismatic Society. His publications under these heads were numerous and varied, dealing with, *e.g.*, the early metallurgy of silver and lead, the remains of a Roman silver refinery at Silchester, the burial mounds and dolmens of the early Emperors of Japan, and silver in pre-historic and proto-historic times. From 1905 to 1907 he acted as president of the Royal Anthropological Institute.

Prof. Gowland was a man of great personal charm and distinction. He was extremely thorough in all he undertook, and never spared himself in the execution of his duty. His lectures were very carefully prepared and well delivered. The geniality of his disposition made him a general favourite with his colleagues and students, and he will always be affectionately remembered at the Royal School of Mines.

H. C. H. C.

E. W. L. HOLT.

IT is with deep regret that we record the death in London on June 10, at the age of fifty-seven, of Mr. Ernest William Lyons Holt, Chief Inspector of Irish Fisheries. Educated at Eton, where he won the Biological Prize, he entered the Army through Sandhurst and joined the Duke of Cornwall's Light Infantry, with whom he served in the Nile Campaign of 1884–5 and afterwards in the Burmah War 1886–7, during which his health broke down and he was invalided home.

Retiring from the Army, Holt took up the study of natural history, in which he had always been interested. His first zoological research was carried out at the St. Andrews Marine Laboratory, and resulted in a paper on the morphology of the brain of fishes, especially of the herring, which was communicated in 1890 to the Royal Society of London. In the same year he was appointed assistant-naturalist for the survey of fishing grounds on the west coast of Ireland, which was being carried out by the Royal Dublin Society. As the result of cruises carried out in 1890 and 1891 a valuable series of papers was published, the most important of which dealt with the eggs and larvæ of fishes, while in others the economic aspects of scientific fishery investigation were ably dealt with.

In 1892 Mr. Holt was appointed by the Marine Biological Association to take charge of a laboratory which was opened near Grimsby for the purpose of studying the fishery problems of the North Sea. Here for three years he successfully carried out investigations dealing with all aspects of fish life in their relation to commercial fisheries, paying special attention to the destruction of immature fish by trawling, a question which was thought at that time to be of the greatest practical importance. On leaving Grimsby, he spent some time in the south of France, where he resumed his studies on eggs and larval stages, publishing a finely illustrated memoir on this aspect of the natural history of Mediterranean fishes. Following this, three years were spent at the Plymouth Marine Laboratory, where he not only continued and extended his work on fishes, but took up the study of several groups of invertebrates which are largely used as food by fishes.

In 1900 Mr. Holt returned to Ireland, where he became scientific adviser to the fisheries branch of the Department of Agriculture and Technical Instruction, succeeding the Rev. W. Spotswood Green as chief inspector of fisheries in 1914. Under his direction an important survey of the fishing grounds, especially to the west and south-west of Ireland, was organised and carried on for a number of years, the deep water of the Atlantic slope receiving a large share of attention. Mr. Holt gathered around him a brilliant staff of young naturalists, and an excellent series of reports was published. He continued to devote himself personally to the study of fishes, and included fresh-water fishes, especially the salmon, in his studies. His personal knowledge of fish life in all its aspects was probably greater than that of any other British naturalist, and at the same time he was a keen student of the literature of the subject. In his earlier years he had great facility as a draughtsman, and his papers were beautifully illustrated with his own drawings. He possessed an acute and critical intellect, a sound sense of proportion, and a quick eye for the things that really mattered in connexion with any question he took up. His work was greatly helped by a gift of rapid literary expression, accompanied by a quiet humour, which always made his writings interesting. His mind was essentially honest, he suffered from no illusions, and did his best to destroy what he thought were illusions in others.

E. J. A.

WE much regret to announce the death, on June 26, at the age of seventy-three years, of Albert, Prince of Monaco, well known for his oceanographical research work.

WE regret to see the announcement of the death, on June 22, of Sir Alexander M'Robert, at the age of sixty-eight years. After acting for a time as a lecturer in experimental physics and in chemistry, in Aberdeen, Sir Alexander went to India, where he passed the greater part of his life, closely associated with technical education. He was made a fellow of the University of Allahabad in the Faculty of Science, served on the committee of management of the Government Engineering College, Roorkee, and also as governor of the Agricultural College, Cawnpore. Sir Alexander had travelled extensively in many parts of the world, and received knighthood for his services in 1910, being created K.B.E. in 1919.

Current Topics and Events.

THE Council of the Zoological Society of London has approved a scheme for the establishment of an aquarium at the Zoological Gardens in Regent's Park The aquarium is to be built under the Mappin Terraces, but so installed as to be invisible from the front, and will not interfere with the panorama of the Terraces. It will consist of a crescentic gallery, 400 ft. long, lined with tanks on both sides. Those on the outer curve will have both daylight and electric illumination, while those on the inner curve will be lighted by electricity only, a method used at the Berlin Aquarium with complete success. The gallery will be divided into three parts—fresh water, marine, and tropical aquaria—with special ponds for seals, diving birds, and trout. The tanks are to be constructed with the bottoms, sides, and backs of slate, and the fronts of polished plate glass set in a framework of white marble They will be provided with rock-work arranged to suit the needs of their inhabitants. The water will be kept constantly circulating, flowing into the tanks from high-level reservoirs and thence through a series of underground filter-beds, on the plan of those in use at the New York Aquarium, to low-level reservoirs, from which it will be pumped by electric pumps to the high-level reservoirs again. Special arrangements are to be installed for heating

the tanks and for regulating the temperature of the water in the different aquaria. The plans for the gallery have been prepared by Messrs. Belcher and Joass, and the circulation, electric plant, and the heating, lighting, and ventilating systems have been designed by Sir Alexander Gibb. The scheme will cost about 50,000*l*., and should provide London with the best-equipped and most carefully arranged aquarium in Europe.

A THIRD attempt to reach the summit of Mount Everest began on June 3 The monsoon being due to arrive early in June, it was clear that this must be the last attempt this season. The *Times* gives an account by Capt. Finch of his ascent with Capt. Bruce to 27,300 ft. in the previous attempt. The oxygen apparatus did not prove satisfactory and only one in ten was fit for use, but by reassembling the sound parts four serviceable sets were obtained By the help of oxygen the climbers reached the North Col perfectly fresh and camped at 25,500 ft. A heavy gale with snow set in and lasted for two days, making progress impossible. When a start was made the Gurkha with the party collapsed and had to be sent back. Eventually, after five hours' diagonal climbing, Messrs. Finch and Bruce reached an altitude of 27,300 ft. The wind and cold were then so severe that they were compelled to turn, and reached No. 3 Camp thoroughly exhausted. A telegram from Jangkok, Sikkim, dated June 22, states that Dr Longstaff, Major Morshead, Colonel Strutt, and Captain Finch have arrived there on their return from Tibet.

THE growing interest in metallography is well illustrated by the establishment of the Metallografiska Institutet of Stockholm, the formal opening of which has recently taken place The new Institute is under the direction of Dr. Carl Benedicks, whose work on the physical chemistry of metals is well known. An inaugural address was delivered by Prof. Arrhenius, who referred to the international character of scientific research, as shown by the presence of foreign representatives at the ceremony, and by the review of the history of metallography contained in the address of Dr. Benedicks. Beginning with the work of Sorby in Sheffield, and continued by many workers, among whom the French worker, Osmond, was prominent, metallographic research has always preserved an international character. It was announced that Sir Robert Hadfield, who has himself made many important contributions to this branch of study, had presented to the Institute an annual sum of 150*l*. for two years, to form a scholarship for a research worker, Englishmen having a preference. In his statement regarding this foundation, Sir Robert Hadfield directs attention to the remarkable contributions made by Sweden to chemistry, and especially to the chemistry of metals. The metals used in the manufacture of alloy steels, such as nickel, cobalt, tungsten, molybdenum, and vanadium, were discovered by Swedish chemists, while direct contributions to metallurgy have been made by many of their compatriots, from Swedenborg and Bergman to Akerman and Brinell. The recent important work of Dr. Westgren on the space lattice of the allotropic modifications of iron, as determined by means of X-rays (NATURE, June 24, p. 817), is an addition to the record of which Sweden may be proud. It must not be forgotten, also, that the Sheffield steel industry owes its existence to the use of the pure Swedish irons obtained from native ores.

THE *Quest* arrived at Cape Town on June 18 from South Georgia *via* Tristan da Cunha and Gough Island. The *Times* announces that, in view of the low power and small size of the ship, it has been decided to abandon the proposed cruise in search of lost islands in the Southern Ocean and to return home. Landings were made at Tristan da Cunha, Inaccessible, Nightingale, and Gough Islands. At the last of these islands several days seem to have been spent ashore, during which some biological collections were made. The visit of the *Scotia* in 1904 showed that Gough Island has a most interesting fauna and flora, particularly worthy of study because the nearest land, with the exception of the Tristan da Cunha group, is South Africa, which is some 1500 miles distant. Details of the *Quest's* deep-sea soundings are not given, but they should be of great interest, since between South Georgia and Tristan da Cunha she traversed an area of the ocean in which practically no soundings have previously been taken.

NEWS from Mr. Knud Rasmussen, published in the *Times*, gives some account of his work in Melville Peninsula and Fox Basin until the middle of last January. The autumn was spent around Lyon Inlet, which offered scope not only for biological work, but also for researches into Eskimo archæology. During the winter, Mr. P. Freuchen was engaged in charting the western coast of Baffin Land against Fox Basin, which was imperfectly known. Mr. Rasmussen himself went south to Chesterfield Inlet near the mouth of Baffin Bay. To the west of this inlet two tribes of inland Eskimo are reported to live. This is of interest because all other tribes of Eskimo are coast dwellers. This autumn Messrs. Rasmussen and Freuchen hope to start on their long journey to the west across the Barren Lands through the area inhabited by the Kinipetu tribe, in an attempt to investigate the original routes of migration of the Eskimo, and to throw light on their origin.

DR. CHARLES D WALCOTT, secretary of the Smithsonian Institution, has left Washington to continue his geological explorations in the Canadian Rocky Mountains Dr. Walcott's work in previous seasons has done much towards clearing up the geological formations of this interesting region, and many thousands of fossil specimens have been brought back to add to the completeness of the exhibition and study series of the U.S. National Museum. One of the important results several years ago was the discovery of fossil bacteria in the pre-Cambrian rocks, probably the earliest form of life on the earth. The section to be studied this year will take in several localities north and south of the Bow Valley between

Banff and Lake Louise on the Canadian Pacific railroad. The particular problems to be attacked are connected with the growth of certain formations and the sequence of marine life in the rocks composing them. It is expected that many photographs of glaciers, mountains, and forests will be obtained.

AT the meeting of the Royal Society of Edinburgh on June 19, the Keith Prize (1919–1921) was presented to Prof. R. A. Sampson for his astronomical researches, including the papers, "Studies in Clocks and Time Keeping: No. 1, Theory of the Maintenance of Motion; No. 2, Tables of the Circular Equation," published in the Proceedings of the Society within the period of the award; and the Neill Prize (1919–1921) was presented to Sir Edward Sharpey Schafer, for his recent contributions to our knowledge of physiology, and in recognition of his published work, extending over a period of fifty years.

WE have received an intimation that the Italian Royal Committee for Scientific Marine Investigations has assumed charge of the Zoological Station at Rovigno, Istria, which was formerly under German administration, and that the station is now in active work, with Prof. Raffaele Issel as Director.

THE second lecture of the series on physics in industry, arranged by the Institute of Physics, will be given on Tuesday, July 4, at 5.30 p.m., in the hall of the Institution of Electrical Engineers, Victoria Embankment, W.C.2, by Sir J. Alfred Ewing, whose subject will be "The Physicist in Engineering Practice, with Special Reference to Applications of Thermodynamics." The chair will be taken by Sir Charles A. Parsons, vice-president of the Institute.

THE fifth international Neo-Malthusian and Birth Control conference will be held in London on July 11–14, under the presidency of Dr. C. V. Drysdale. Many delegates from abroad are expected and the discussions have been arranged to take place in several sections. A visit to Dorking is arranged for July 15. This was the birthplace of the Rev. T. R. Malthus, author of the famous essay on the Principle of Population.

The American Geologist, which in 1905 was merged with *Economic Geology*, now resumes independence as *The Pan-American Geologist*. This monthly journal, devoted to speculative geology, constructive geological criticism, and geological record, is edited by Dr. Charles Keyes, Des Moines, Iowa. The associated editors are Edward W. Berry, Baltimore, Md.; Eliot Blackwelder, Cambridge, Mass.; Henry S. Washington, Washington, D.C.; and Gilbert D. Harris, Ithaca, N.Y. The first issue, volume xxxvii. No. 1, appeared in February last.

RECTANGULAR glass jars suitable for the exhibition of museum specimens were, before the war, generally obtained from Germany. Recently some attempt has been made to draw again on that source, but the difficulties remain considerable. For many years the Museums Association has sought to rouse British manufacturers to the desirability of meeting the ever-increasing need, but it is only now that any satisfactory result has been attained. We understand that there are at least two firms willing and able to meet the demand. The June number of the *Museums Journal* publishes a list of the sizes that can readily be made and asks curators to state their needs without delay. We regret to learn that Dr. Tattersall, the secretary of the Association, to whom this development is due, is at present ill, but letters may be addressed to the Secretary of the Museums Association, care of E. E. Lowe, The Museum, Leicester.

THE Journal of the Society of Glass Technology of May contains papers on the melting of glass, the action of analytical reagents on glass, methods used in determining the durability of glass, Zulkowski's theory of the relation between the composition and durability of glasses, and other subjects. It is clear from the contents of various issues of this journal which have been received that research on glass and matters relating thereto is proceeding in a very satisfactory manner, and the great improvements which must result from this scientific investigation may be expected to have a most beneficial effect on the British glass industry. It is satisfactory to note that the Journal is acquiring an international status, since one paper in the present issue comes from the Geophysical Laboratory of the Carnegie Institution of Washington, although many of the best papers owe their inception to the work of Prof. Turner, of the Department of Glass Technology of the University of Sheffield.

ON Wednesday June 7, a lecture was given by Prof. A. F. Holleman, of Amsterdam, at the Imperial College of Science and Technology, under the auspices of the University of London, entitled "Recent Researches on Substitution in the Benzene Nucleus." After a brief statement of the position of the subject at the time (1910) of the publication of his book, "Die direkt Einfuhrung von Substituenten in den Benzolkern," Prof. Holleman dealt with the qualitative and quantitative investigations which have since been carried out in the laboratories at Amsterdam. Considering the matter in the light of his own and Boeseken's theory as to the mechanism of substitution (involving primary addition to one or other of the Kekulé double bonds), it was shown that in many complex instances the extent to which substituents enter the different positions can be predicted with fair accuracy from the general rules which have emerged from the experimental study of the simpler cases. Full emphasis was laid on the exceptions and unforeseen results. Indeed the whole discourse was highly critical and gave an illuminating insight into the methods by which, under Prof. Holleman's direction, the workers at Amsterdam are gradually reducing to ordered measure the whole chemistry of benzene substitution.

IN the editorial remarks in the opening pages of the Journal of the British Science Guild for May, attention is directed to a departure, namely, the inclusion of matter going beyond the actual records of the work of the Guild. No doubt the wider scope

thus afforded in emphasising the benefits of applied science will be appreciated by readers. Interesting light is shed on two incidents during the war—the Coronel sea-battle and the German advance in 1914—both illustrating the importance of accurate information regarding warfare on land and sea. Among other matters that are the subject of editorial comment may be mentioned "The Science of Sailing," "The Bases of Politics," and "The Need for a Scientific Missionary Journal." Much of the issue is naturally devoted to the annual report of the Guild and the annual meeting. Special interest attaches to the address of Sir Richard Gregory explaining the origin of the appeal to be conducted by Commdr. L. C. Bernacchi for funds to consolidate and extend the Guild's activities. Among other important steps may be mentioned the establishment of local branches of the Guild and the completion of the catalogue of scientific books, comprising over 6000 entries—in itself a remarkable piece of work that justifies the Guild's existence. A summary is given of Sir Leslie Mackenzie's address at the Edinburgh meeting of the British Association on "Science and Citizenship," and a tribute is paid to the memory of Sir Ernest Shackleton, whose passing away on the *Quest* at the commencement of this year will be fresh in the minds of readers, and whose achievements in the field of polar exploration will not soon be forgotten.

A NEW catalogue (No. 94) of second-hand works on Zoology, Botany, and Agriculture has been issued by Messrs. Dulau & Co., Ltd., 34 Margaret Street, W.1. Among the 1400 volumes listed are two of especial interest, namely, a nearly complete set of *Curtis's Botanical Magazine*, formerly the property of Sir Joseph Hooker, with MS. corrections in nomenclature by Sir W. J. and Sir J. D. Hooker, and an unusual French Herbal, entitled "Recueil des plantes les plus usuelles peintes d'après Nature," in 12 vols. containing nearly 5000 illustrations drawn and coloured by hand, with manuscript descriptions.

MESSRS. W. HEFFER & SONS, Ltd., Cambridge, have just issued a list (No. 213) of some 600 works in new condition which they offer at greatly reduced prices. Many of the books listed deal with scientific subjects. The catalogue is obtainable from the publishers upon request.

A REPORT of the address given by Mr. F. W. Sanderson to the National Union of Scientific Workers, just before his death, is to be published shortly. Copies may be obtained from Maj. A. G. Church, General Secretary, 25 Victoria Street, S.W.1.

THE firm of Mr. T. Fisher Unwin, Ltd., 1 Adelphi Terrace, London, W.C.2, is arranging for the publication of the memoirs of Sir William Crookes, edited by Dr Fournier d'Albe. Any letters and information likely to be useful to the editor will be gratefully received and carefully preserved and returned.

Our Astronomical Column.

SKJELLERUP'S COMET, 1922 *b*.—This proves to be a short-period comet of the Jupiter comet-family. The following elliptical orbit has been derived from observations on May 20, 31, June 12, the third being by Dr. W. H. Steavenson at Norwood:

$$T = 1922, \text{ May } 15, 0\cdot0325 \text{ G.M.T.}$$
$$\left.\begin{aligned} \omega &= 354^\circ\ 47'\cdot20 \\ \Omega &= 215^\circ\ 43'\cdot31 \\ i &= 17^\circ\ \ 23\ \ 36 \\ \phi &= 43^\circ\ \ \ 9'\cdot00 \end{aligned}\right\} 1922\cdot0$$
$$\log a = 0\cdot44930.$$
$$\log q = 9\cdot94904.$$
$$\text{Period} = 4\cdot7201 \text{ years.}$$

These elements indicate a much closer approach to the earth than the parabolic elements did. Prof. Leuschner has pointed out that the comet is probably identical with 1902 II, discovered by Mr John Grigg in New Zealand, and followed by him for 11 days. No one else saw it, and the observations were too rough to give a good orbit. If the period of less than 5 years is confirmed it will be the second shortest cometary period known, that of Encke, 3·3 years, being the shortest.

SOLAR ATMOSPHERIC CHANGES.—In the current number of the Monthly Notices of the Royal Astronomical Society (April) there are three communications relative to solar activity. The first is by Dr. William J. S. Lockyer, and deals with the relationship between solar prominences and the corona. In 1903 Dr. Lockyer published a paper on the same subject, concluding that the various forms of the corona, as photographed during eclipses, were dependent on the positions and intensities of the zones of prominence activity. In the present paper, using quite independent prominence and corona data, the former extending over the period 1890–1920 and thus including three sunspot maxima and minima, he points out that the previous conclusion is well endorsed by these new observations. Mr. A. M. Newbegin publishes the results of his solar prominence observations for the year 1921 and gives curves showing mean areas and mean numbers. He shows that the main zones of prominences were situated in latitudes 40° N. and 55° S., and a much lesser zone of activity in latitudes 10° N. and 25° S. These zones are in conformity with the curves of latitudes of prominences illustrated in Dr. Lockyer's paper referred to above, the higher latitude zones being the commencement of a new zone of activity which will gradually move polewards.

Mr. C. P. Butler communicates a first paper on the systematic distribution of Solar calcium flocculi, this contribution dealing with inclination of elongated groups. Several observers have previously shown that the mean inclinations of the axes of sunspot groups were found to vary from 0° to 11°, and that the amount of inclination increases with the solar latitude of the group. Mr. Butler has investigated the case of the areas of calcium flocculi as determined from measures taken from photographs secured with the spectroheliograph. He concludes that the inclinations range in general from 0° to 40°, with a few cases of specially high inclination. The range is therefore much greater than that found for spot-groups. In the above range there are maximum frequencies at certain latitudes, namely, 15°, 21°, and 28°–32°. Other more detailed results are given.

Research Items.

PROBLEMS OF RACE AND NATIONALITY IN SOUTH AFRICA.—The problems of race and nationality are discussed in the presidential address delivered before the South African Association for the Advancement of Science by the president, Dr. J. E. Duerden. He gives an instructive survey of the social condition of the Bantu races and of the European immigrants. The hereditary attributes of all the people of colour are markedly inferior to the white in all that pertains to the requirements of modern civilisation, and there is every reason to expect that they will remain so in the future, "for in considerations of this nature the teachings of zoology are overwhelmingly in favour of the unchangeableness of the germ plasm" He goes on to say that the Nordic race, represented by the English and Dutch, stands at the head of the human genus, and "it is in the daily competition with those that the Bantu, Indian, and Malay are to lead their lives. In the commingling of these races in South Africa there can be no question as to which will be dominant. In his hereditary endowments the white is far more gifted than the coloured, and must lead Dominance, however, is not arrogance, nor does superiority necessarily carry with it harshness or unfairness."

SECRET SOCIETIES IN THE SOUTHERN SUDAN.—The spread of secret societies among the Sudanese is a question of some political importance, and the reports of several correspondents on the subject are summarised in *Sudan Notes and Records* (vol iv No. 4). The baneful influence of such associations has attracted the attention of the Government, which has recently revised "The Unlawful Societies' Ordinance" in order to bring them under control The authorities emphasise their evil influence through terrorism, debauch, and robbery, and it is suggested that they are mainly the work of unscrupulous persons who exploit the fears of primitive man for their own nefarious ends. But, as is the case with similar organisations among tribes of the lower culture elsewhere, it is believed that the use of "fetish" or other magical objects in their rites implies a religious side to the practices of these societies which deserves to be more closely studied It would be interesting to learn whether these cults are regarded as supplementary or antagonistic to the traditional beliefs and rites of the uninitiated members of the community, and whether their influence depends on the transitory prestige of some particular leader, or is deeply rooted in the official religion of the tribe

GEOLOGY OF MESOPOTAMIA.—An interesting memoir just issued by the Geological Survey of India (Memoirs, vol. xlviii, 1922) embodies the results of Dr. E. H. Pascoe's reconnaissance of the part of Mesopotamia lying mainly to the east of the Tigris from about the latitude of Baghdad to that of the Great Zab river just below Mosul Excluding the recent alluvium and the pleistocene conglomerates, the rock groups described are all of Tertiary age and fall naturally into two divisions—(a) a lower, marine, gypsiferous series corresponding to a part of Dr. Pilgrim's Fars series of the Persian Gulf region; and (b) a younger fluviatile series, which is provisionally named the Kurd series and corresponds generally with the beds distinguished by Dr Pilgrim as the Bakhtiyari series in Persia. The older, marine, gypsiferous beds were laid down in a relatively shallow gulf, which became silted up and finally gave place to fluviatile conditions after an intermediate stage of salt lagoons. Local erosion naturally occurred during this transition stage, but there is no general or widespread unconformity dividing the marine from the later freshwater formations by which the former were covered. Folding of the sediments commenced in Fars times and became accentuated during the subsequent Kurd period, persisting into recent times; this is indicated by the marked steepening of the dips noticeable in passing from the upper to the lower series, while there is in general a marked contrast between the compressed condition of the anticlines and the open disposition of the alternating synclinal folds, which Dr. Pascoe ascribes to the circumstance that the rising anticlinal saddles became eroded and consequently weakened, thus yielding more readily to compressional earth-movements Petroleum is of outstanding importance among the minerals of economic value, and the conditions for its occurrence are so favourable that Dr Pascoe regards Mesopotamia as a possible rival of Persia, outclassing Burma altogether in oil resources Associated with the oil are small quantities of pitch and bitumen, while sulphuretted hydrogen is evolved in such large quantities that its recovery as a source of sulphur (or alternatively as sulphuric acid) is recommended as commercially feasible.

AMERICAN CRETACEOUS DINOSAURS.—The first of a series of preliminary notices on the Cretaceous dinosaurs, obtained in Alberta from 1910 to 1915 by parties sent out by the American Museum of Natural History under Mr. Barnum Brown, has been issued. The article in question, by W. D. Matthew and B. Brown (Bull. Amer. Mus. Nat. Hist., vol. xlvi.) treats of "The family Deinodontidæ." This family name was introduced by Cope in 1866, under what is now considered the more correct rendering for the Greek, as Dinodontidæ, but the authors of the present brochure have altered it, presumably because the type genus, when founded by Leidy in 1856, was rendered, as then customary, as Deinodon. But if Leidy's original is to be scrupulously adhered to, why not Cope's? The authors discuss the group and give a most valuable "Chronological list of American Cretaceous Deinodonts and Ornithomids." Appended is a description of *Dromæosaurus albertensis*, n. gen. et sp, from the Cretaceous of Alberta, and the conclusion is reached that it should be placed in a distinct subfamily, Dromæosaurinæ

ENTELODONTS FROM THE OLIGOCENE OF SOUTH DAKOTA.—W J Sinclair describes the "Entelodonts from the Big Badlands of South Dakota in the Geological Museum of Princeton University" (Proc. Amer Phil Soc., vol lx), some of which had been previously inadequately determined, and had even figured in literature under other names. The new forms include two new species of Archæotherium and *Scaptohyus altidens*, n gen. et sp The origin of the group as a whole is uncertain. Apart from the digging proclivities of Scaptohyus, one of the most clearly indicated "habits" of the entelodonts, according to the author, judging from lesions in the preserved remains, appears to have been their pugnacity; but surely the argument is equally allowable that the injuries were due to attacks by powerful enemies.

PETROLEUM IN THE PHILIPPINES.—In the *Philippine Journal of Science* of January last, Dr. Warren D. Smith gives a detailed account of his geological reconnaissance of the Pidatan Oilfield, Cotabato Province, Mindanao, the second largest island of the Philippine group. The occurrence of petroleum in the Philippine Islands has been known for some years, surface indications existing in Luzon, Mindoro,

Panay, Cebu, and Leyte; those of the Cotabato district in Mindanao, in particular the Pidatan seepage, are of more recent discovery, Pidatan not receiving detailed geological attention until the expedition of 1921, of which this paper is a report. The Pidatan field is about 60 kilometres north of Fort Pikit, Cotabato Province, the basin of the Rio Grande de Cotabato, practically in the centre of the island. The topography is mountainous and the country is exceedingly difficult. Geologically, the formations present consist principally of Tertiary limestones, sandstones, and shales pierced by basaltic and andesitic intrusions. The sediments are of recent, Pleistocene, Pliocene, and Miocene ages, many horizons yielding fossil evidence. The structures, however, appear to be very complex, owing to the regional earth movements and the igneous activity manifested. In fact, the faulting and folding has so disturbed the oilfield region that Dr. Smith does not hesitate to condemn the area from the economic point of view. On the other hand, the presence of the seepage and the nature of the oil involved at Pidatan suggest that petroleum certainly occurs in central Mindanao, possibly over an extensive region, and the advisability of intensive geological exploration over a wider area is clearly indicated. Analysis of the oil from the occurrence at Pidatan shows that it has a specific gravity of 0·9297 and is of paraffin base; no light fraction was obtained (under 150° C.), kerosene and heavy oil representing 45 per cent. and 49·5 per cent. of the sample respectively (by volume). Results of other tests indicate that the oil is much inspissated, as would be expected considering the geological circumstances, and is most suitable for use as a Diesel engine fuel. The author concludes his paper with a commendable caution to those controlling oil companies against belittling the value of sound geological work as a necessary preliminary to oil exploration; while not detracting from the value of the "practical" man's work, he makes it quite clear that success is achieved only where both driller and geologist work in harmony, a conclusion deserving of serious consideration by many of the would-be "wild-cat" oil explorers in our own colonies.

The Geology of the Mount Everest District.—The Mount Everest expedition of last year included among its staff Dr. A. M. Heron, who contributes to the *Geographical Journal* of June an account of his geological investigations, accompanied by a geological map. The mapping is virtually a westward continuation of Sir H. Hayden's investigations during the Tibet Expedition of 1903–4. Dr. Heron's task was one of unusual difficulty. Over much of the area examined his work had to proceed in advance of surveys, while the movements of the expedition were generally unfavourable to detailed work. Close and prolonged examination, moreover, was considered inadvisable, since it aroused the suspicions of the Tibetans. Dr. Heron claims that his work must be looked on only as a reconnaissance. The area examined covers more than 8000 square miles, and consists in the main of the Tibetan portion of the drainage area of the Arun river above Kharta. Two geological divisions can be recognised: a Tibetan area of sedimentary rocks which consists chiefly of east and west folds of Jurassic slates, and the crystalline Himalayan region to the south. The contrasts in topography clearly illustrate the differences in the underlying structure. On one hand are the somewhat tame rounded ranges, with broad valleys, of Tibet, and on the other the high, steep, and rugged Himalayas.

Recovery of Sugar from Beet Molasses.—Beet molasses is a substance of almost constant composition, containing 50 per cent. of sugar, 10 per cent. of ash, 15 per cent. of other organic substances, and 25 per cent. of water. The sugar cannot be separated from it by direct means, and among the methods employed for recovering the sugar is precipitation by one of the alkali earths. Until the present lime and strontia have chiefly been used. In the year 1838, however, Peligot found that baryta forms a very sparingly soluble saccharate. The use of baryta for the purpose of separating sugar was never carried out to any great extent for two reasons; (*a*) its cost, and (*b*) the poisonous nature of barium compounds. The cost of baryta should now be considerably reduced by the discovery of two French chemists, MM. Camille Deguide and Paul Baud (*Comptes rendus*, May 1), who find that when barium carbonate is heated with silica at a temperature of 150°-200° C., and the mixture subsequently lixiviated with water, the carbonate is to the extent of more than 90 per cent. converted into hydroxide. This process should therefore render baryta available for the desaccharification of molasses. It is, however, very doubtful whether any Government will permit its use on account of the toxic character of traces of barium compounds.

Pyrex Glass.—The *Chemiker Zeitung* of May 25 contains an analysis of the "Pyrex glass" manufactured in America and used for cooking vessels. This glass is an astonishing resistant to changes of temperature, and may be used over an open fire. The chemical composition was found to be, in percentages: silica, 80·71; boric anhydride (B_2O_3), 10·47; alumina, 3·55; lime, 0·70; magnesia, 0·57; soda (Na_2O), 4·14. The low alkali content is noteworthy. Experiments showed that ordinary heating is not sufficient to melt the materials for such a glass, and special furnaces, possibly with surface-combustion heating, are assumed.

Safety Devices in Wireless Equipment.—The American Bureau of Standards has given its approval to the recommendations of a committee of the National Fire Protection Association proposing the addition of some new safety rules to the National Electric Code relating to wireless telegraph installations. The proposed regulations provide for the protection of receiving and transmitting equipment against lightning effects, avoidance of risk of contact with neighbouring electric light and power circuits, and protection from effects of high potential surges in the lines supplying power to the equipment, as well as the ordinary requirements of sound construction. It is needless to detail all the proposals, but it may be remarked that, in the case of receiving equipments, a lightning arrester is required where the leading-in wire enters a building and, on account of the larger size of the ordinary transmitting aerial, which is more likely to be subject to damage from lightning, and the high voltages produced in the apparatus, the provision is recommended in transmitting stations of a double-throw switch for connecting the aerial either to the transmitting apparatus or to earth. The use of this switch makes it possible to disconnect the aerial entirely from the transmitting apparatus. On account also of the difficulty which has been experienced by the induction of voltages in the supply lines of a transmitting station, it is advisable to use a protective device across the power line near its point of entrance. It is noticeable that copper-clad steel wire is recommended throughout as an alternative to copper wire, owing to the fact that these two kinds of wire are practically equivalent in their conductivity for high-frequency current, while the former is stronger mechanically.

Quantum Mechanism in the Atom.

AT a meeting of the Royal Society of Edinburgh on May 8 Prof. E. T. Whittaker read a paper on the quantum mechanism in the atom (since published in Proc. Roy. Soc. Edin., vol. xlii. pp. 129-142).

Prof. Whittaker shows that it is possible to explain quantum phenomena satisfactorily in terms of the classical electrodynamics without postulating any structure in the atom beyond that by which it is customary to explain induced magnetisation. The author considers the effect of an approaching electron in producing a "magnetic current" in the atom; up to a certain velocity of approach the electron does not get beyond the atom but suffers an "elastic impact" which repels it without loss of energy. When, however, the velocity of approach exceeds this critical value the electron passes through the magnetic atom and gives to it energy of exactly that amount or quantum which corresponds with the critical velocity. The transformation of this energy into radiant energy can be explained by generalising the conception; thus the magnetic current becomes equivalent to a charged condenser, partaking of the nature of a Hertzian oscillator. By a simple mathematical process, combined with the assumption that the oscillators in the atoms are similar to each other in structure and differ only in scale, the equation $h\nu = U$ can be established, giving Planck's relation connecting the frequency, ν, of the emitted radiation with the amount of kinetic energy U, absorbed from the bombarding electron. A more definite form to the quantum mechanism is given by linking a conducting circuit with the magnetic structure. Photo-electric phenomena can be interpreted on the basis of this theory, and Bohr's theory of series-spectra likewise finds an explanation.

Sir Alfred Ewing suggested that instead of following Prof. Whittaker in leaving the magnetic atomic model at a certain point there is perhaps an advantage in not dropping the model, especially as it seems to give an immediate explanation of the manner in which oscillations are set up as the electron parts with its quantum of energy. In the Ewing magnetic model the central magnetic system or wheel is controlled by an outer system or ring. When an electron passes through and escapes it gives an impulse producing relative angular displacement of inner wheel and outer ring, and the mutual magnetic forces tend to restore the original configuration. Oscillations are set up which expend their energy in emitted radiation. Conversely, in an atom in which oscillations are going on, an electron may be ejected (photo-electric effect). In being ejected it exerts an angular impulse which stops the oscillation and deprives the atom of the quantum of energy originally absorbed through resonance.

Dr. H. S. Allen directed attention to the fact that in Prof. Whittaker's "calamoids," or four-dimensional tubes of electromagnetic force, as well as in the Ewing magnetic model, magnetic forces rank on an equality with electrostatic forces. The number of magnetic tubes associated with Prof. Whittaker's magneton must be an integral number of times the unit quantum tube of magnetic induction. More satisfactory is a modified form of the quantum mechanism, in which two ring electrons are placed near together on the same axis, the electromagnetic force between them being repulsive. Such models cannot, in Dr. Allen's opinion, "reconcile" quantum dynamics with classical dynamics.

Dr R A Houstoun suggested the advisability of testing Prof. Whittaker's theory by an appeal to numerical calculation, introducing, for example, definite values of the frequency and calculating the corresponding size of the molecule. The results appear to be satisfactory considering the simple nature of the assumptions made. It seems that the reciprocity which exists between electric and magnetic quantities in the electromagnetic wave must be extended to atomic structure

Prof Peddie remarked that the value of Prof. Whittaker's idea does not lie in its being an "only possible" one, for other possibilities exist. Its importance rests on the fact that the idea is a new one, giving for the first time an action on an electron which is not reversed in direction when the electron passes through an atom A "perfectly elastic" collision seems to be attainable only by implicitly denying collisional radiation, which leaves part of the essential mechanism undescribed. The interactions of the atomic charges, ether and the "magnetic currents," may perhaps introduce difficulty regarding atomic subjection to the Newtonian first law of motion.

The Second Royal Society Conversazione.

THE second conversazione of the Royal Society this year was held in the rooms of the Society at Burlington House on the evening of June 20, when the president, Sir Charles Sherrington, with Lady Sherrington, and the officers of the Society, received a large number of fellows and guests Many interesting scientific instruments and specimens were shown, several of which were exhibited at the first conversazione held on May 17, and some were briefly described in NATURE of May 27, p. 693. Below are brief descriptions of other noteworthy exhibits.

Some selections from the contents of large prehistoric cooking-places at Buckenham, Tofts Park, Norfolk, were shown by Miss Nina F. Layard. The specimens were found by Miss Layard and Miss M. F. Outram in 1921–1922, and they include hearth-stones, heating-stones, bones and teeth of animals, fragments of pottery, flint flakes and implements. Mrs. Clayton exhibited a Roman bronze measure of capacity, made under Domitian, which was found during draining works in the vicinity of the Roman Wall, three miles east of Gilsland, Northumberland.

A simple form of respiration meter was exhibited by Mr. H. F. Pierce. Two bellows are mounted on a vertical shaft, one of which measures the volume of inspired air, the other the volume of expired air. The latter is measured at a temperature of 37·2° C. to avoid error due to condensation of contained moisture. Respiration is recorded quantitatively upon a smoked drum. The moving parts are made very light and valves are operated electrically.

Mr. G C. Robson had an exhibit showing that a highly differentiated character which appears discontinuously in the parthenogenetic gastropod, *Paludestrina jenkinsi*, does not reappear in two generations bred from parents showing this character. There is evidence that this character cannot be compared with an ordinary "fluctuating" variation.

The Royal Botanic Gardens, Kew, showed a double coconut, or Coco de Mer, from the Seychelles, which

was germinating. The massive cotyledonary tube emerges from the nut, carrying the plumule and radicle out of the seed, and later the plumule pushes through the tube and grows up into the air. Specimens of the tubers of Ecanda rubber (*Raphionacme utilis*, Brown and Stapf) from Angola, which sometimes weigh as much as 15 lbs., and contain valuable rubber, were also shown.

Mr. W. Barlow exhibited some models of organic substances which are based on the law of valency-volumes and are in harmony with the Bragg structure found in the diamond. The valency-volume unit-cell appropriate for the carbon compounds is a rhombic-dodecahedron. The fundamental valency of carbon is expressed by a close tetrahedral group formed of four of the cells—that of nitrogen by three cells triangularly arranged, that of oxygen by two cells in face-contact, and that of hydrogen by a single cell. By fitting together appropriate numbers of these cells representing the composition and constitution of various compounds, structures can be made representing molecules which present internal symmetry closely corresponding with that of the crystal forms of these organic substances.

The Research Department, Woolwich, had an exhibit showing the time reaction in the colour change of Congo red in organic solvents. The change from red to blue which occurs during titration is associated with its flocculation from the colloidal condition and forms a time reaction related to the concentration of H ions and other properties of the solvent. There were also exhibits from the Air Ministry (Instrument Section), among which was a radiator temperature outfit designed to determine the temperature distribution at different points on an aero-engine radiator and its connecting pipes. A six-junction thermocouple is used, and each set of junctions measures the temperature relative to that of the atmosphere. Another exhibit was a Filon aneroid dial for indicating to the pilot the height of an aeroplane above the ground. The scale is coiled into a spiral groove so that it can be adjusted to meet daily changes in temperature and barometric pressure. A metallic oxygen container was also shown in which a small quantity of silica-gel has been used successfully for cleaning up residual gases.

Mr. A. A. Campbell Swinton demonstrated the recording of wireless telegraphic messages. A short aerial on the roof of the building was connected through a tuner to a thermionic three valve amplifier, which in turn was connected to a 1 to 9 valve note magnifier. A moving coil siphon recorder was used, connected to the note-magnifier, either through a Brown relay, or through a very low frequency thermionic amplifier tuned to respond to the frequency of Morse signals. For the reception of continuous wave signals a separate thermionic heterodyne oscillator is employed which renders the high frequency signals audible by means of musical "beats."

Dr. H. E. Hurst and Mr. D. A. Watt exhibited an interesting model, on a scale of 1 : 50, of the sluice of Aswan dam which is used for calibration purposes. The relation between Q, the discharge of the actual sluice, and q the discharge of the model is given very closely by $Q/q = n^{5/2}$, where n is the scale ratio.

Psychical Monism.

THE Journal of the Washington Academy of Sciences of March 19 contains a communication from Mr. L. T. Troland of Harvard University entitled "Psychophysics as the Key to the Mysteries of Physics and Metaphysics." The article is interesting as a revival of the once famous theory of mind-stuff put forward by W. K. Clifford in his lecture on "The Nature of Things in Themselves." Mr. Troland connects it with several recent philosophical theories of psychical monism and brings it forward with particular reference to the consequences of adopting the principle of relativity and the quantum theory in physics, both of which, he contends, demand the recognition of the ultimate psychical nature of physical reality.

The essence of the mind-stuff theory is that it supposes mind to be constituted and articulated, not merely on the analogy of physical reality but on one and the same principle, so that a parallelism runs throughout the universe between mind and matter. Every electron or proton has not only a psychical aspect but in its ultimate nature is a constituent of mind, a bit of mind-stuff. Just as the unit of physics, the electric charge, enters into combination in atoms, molecules, and their more or less stable compounds, acquiring thereby the various physical and chemical properties of things, so in mind-stuff combines to acquire the various sensations, emotional, and intellectual properties of personality.

Mr. Troland's argument is interesting but scarcely convincing. He thinks by the theory to get rid of Berkeley's difficulty that no qualities of the primary or secondary, are independent of the observing individual. The new realists, though they have recently attacked Berkeley, have not, he thinks, succeeded as yet in developing an explanation of the universe which is either simple or plausible.

The difficulty of Mr Troland's theory, however, if offered as a support of Einstein, would seem to be that it misses the essential difference between the activity of the observer co-ordinating events in space-time systems and the intersecting world-lines which present the events co-ordinated. The theory of knowledge we are waiting for in science as well as in philosophy is one which will give full meaning to the subjective and objective factors without sacrificing either to the other. Psychical monism seems to be no more successful than physical monism as a key to the mysteries of physics and metaphysics, but we commend Mr. Troland's argument, which includes in its scope recent physiological research as well as the new physical theories.

Technical Education.

THE annual conference of the Association of Teachers in Technical Institutions was held on June 5-7 in London, and in the course of his presidential address, Mr. J. Paley Yorke claimed very strongly that technical education is definitely education and is as essential as any other branch of educational activity. He said that technical education is essentially scientific education, and urged that the advance of scientific knowledge and the development of the applications of science to industry and manufacture have been so tremendous that the time has arrived when a special committee of inquiry should be appointed to investigate the whole field of technical education in relation to industry and to education generally. It is now forty years since there has been any national inquiry on technical

education, and during that time it has developed beyond the recognition of many of those who imagined themselves to be its guardians.

Mr. Paley Yorke protested against the charge of soullessness that is sometimes levelled at scientific education, and argued that it gives an extended vision and develops both imagination and that too rare gift of being able to marvel at the wonders of nature and to appreciate the beauties of life. It cannot be admitted that a good general education can be obtained only by the study of certain subjects in certain ways or that education and culture must be associated necessarily with bygone civilisations.

Reference was made to the fact that opportunity for contact with industry and for research is scant, and it was urged that directors of industry might submit some of their research problems to local Education Authorities and through them to the scientific and technical staffs of the various technical institutions in the area. It is realised, of course, that all problems would not arrive that way because of the publicity involved, but some useful work may be done.

Attention was also directed to the proposed reduction of grants for scientific research and to the reduction in the number of national scholarships for higher education It was pointed out that not only do these reductions gravely imperil scientific and industrial development, but also that the percentage reduction in the estimates for these items is much greater than that for corresponding items in other branches of educational work.

Lord Burnham said that technical education is slowly gaining its right place in the assessment of national values This country, with its superiority in industrial matters during the greater part of the nineteenth century, looked with supreme self-confidence upon the efforts of other nations to compete with us in industrial production. When the advance of scientific discovery showed that mere manual dexterity was not sufficient the necessity for technical education was admitted. Lord Burnham doubted whether there is any other class of teacher upon which the future prosperity of the nation depended so much. Technical teachers are striving to shape education for the public good and for the welfare of the generations which are coming to manhood

Resolutions asking for the appointment of a committee of inquiry to investigate the whole field of technical education in relation to education generally and to industry, and expressing alarm at the reduction in the number and value of scholarships available for higher education, were carried unanimously.

University and Educational Intelligence.

BRISTOL.—The J. S Fry and Sons, Ltd, Colston Research Fellowship, which provides for payment of fees and a maintenance allowance of 150*l.* a year, has been awarded to Mr. F B. Wrightson, a student in the Faculty of Engineering.

CAMBRIDGE.—Mr. W. B. R King, fellow of Jesus College, has been elected to be fellow and lecturer in natural sciences at Magdalene College, Mr P M S. Blackett to be Charles Kingsley Bye fellow of Magdalene College; Mr. L. E. Bayliss, Trinity College, to be Michael Foster student in physiology; Mr. F. Lavington and Mr. J. Line, to be fellows of Emmanuel College; and Mr. J. A. Carroll to be fellow of Sidney Sussex College.

GLASGOW.—Mr. A. D. Lindsay has been appointed to the chair of moral philosophy in succession to the late Sir Henry Jones. Mr. Lindsay was formerly Shaw Fellow of the University of Edinburgh, and lecturer in philosophy at the old Victoria University. In 1906 he was elected Fellow of Balliol College, Oxford, and was appointed classical tutor and Jowett lecturer in philosophy.

LEEDS.—The Council has appointed Dr. W. T. David to be professor of civil and mechanical engineering in succession to Prof. J. Goodman, who retires in October next. Dr. David, who is at present professor of engineering at the University College of South Wales, was educated at Cardiff and Cambridge. He served as demonstrator in engineering under Prof. Bertram Hopkinson at Cambridge for two years, and later was appointed H.M. Inspector of Technical Colleges under the Board of Education. His research work has been concerned mostly with internal combustion engines

The handsome gift received some little time ago from Col Sir Edward Brotherton of 20,000*l.* has enabled the University to make an important development in the work of the department of pathology and bacteriology. Sir Edward's intention was that his gift should be devoted to the furtherance of the study of bacteriology with special reference to public health, and as a step in this direction the Council has instituted a new professorship to be called "The Sir Edward Brotherton Chair of Bacteriology." Dr. J. W McLeod has been elected as the first holder of this chair. Dr McLeod graduated with commendation at Glasgow University in the summer of 1908, and after acting as house physician at the Glasgow Royal Infirmary and house surgeon at the Glasgow Western Infirmary, gained the Coats research scholarship and worked for a year under Prof. R. Muir. Later he was appointed assistant lecturer and demonstrator in pathology at the Medical School of the Charing Cross Hospital, and afterwards lecturer in bacteriology at the University of Leeds. Dr. McLeod has carried out important research work in the field of bacteriology, and has published numerous papers dealing more especially with the bacteriology of influenza, dysentery, pneumonia, and the streptococcal infections

LONDON.—At a meeting of the Senate on June 21, Mr. H J Waring, Dean of the Faculty of Medicine and vice-president of St. Bartholomew's Hospital Medical College, was elected Vice-Chancellor for 1922-23, in succession to Sir Sydney Russell-Wells. A cordial vote of thanks was passed to Sir Sydney Russell-Wells for the services which he had rendered to the University as Vice-Chancellor since December 1919

Mr. J. H. Woodger was appointed to the University readership in biology tenable at Middlesex Hospital Medical School. Mr. Woodger was educated at University College, whence he graduated in zoology, and was awarded the Derby Research Scholarship In 1917 he was appointed protozoologist to the Central Clinical Laboratory in Amarah, and in 1919 assistant in zoology at University College.

Sir Charles W. C Oman, Chichele professor of modern history in the University of Oxford, was appointed Creighton lecturer for the year 1922-23. The subject of his lecture will be "Historical Perspective."

The Lindley studentship for 1922, of the value of 120*l.* and tenable in the Physiological Laboratory, has been awarded to Miss M. J. Wilson-Smith of Royal Holloway College; and the University studentship in physiology for 1922-23, of the value of 50*l.* and tenable in the Physiological Laboratory of the University or of one of its Schools, to Miss M. M. A. Murray of Bedford College.

MANCHESTER.—Mr. E. D. Telford, lecturer in practical surgery in the University, and a member of the Honorary Staff of the Manchester Royal Infirmary, has been appointed professor of systematic surgery.

BY the will of the late Sir William Lorimer, who died on April 9 last, the Court of the University of Glasgow will receive the sum of 10,000*l*.

IT is announced in *Science* that, by the will of the late Amos F. Eno, Columbia University, New York, will receive a bequest of about four million dollars.

THE Beaney Scholarship in Materia Medica at Guy's Hospital Medical School is vacant. It is of the yearly value of about 50*l*. and tenable for three years. It is open to candidates who have received at least part of their medical education at Guy's Hospital. The latest date for receiving applications is July 7. They should be sent to the Dean of the School, S.E. 1.

THE Gull studentship in pathology and allied subjects, of the annual value of about 250*l*. and tenable for three years, is being offered by Guy's Hospital Medical School. The studentship is open to candidates under 35 years of age who have studied in the school. Applications must reach the Secretary to the Board of Electors, Guy's Hospital Medical School, S.E.1, by, at latest, July 7.

THE summer meeting of the Association of Technical Institutions will be held at Oxford on Friday and Saturday, July 7 and 8. The sessions on Friday and Saturday mornings will commence at 10 30 o'clock, when the president, The Right Hon Walter Runciman, will occupy the chair The Rev. L R Phelps, Provost of Oriel College and Pro-Vice-Chancellor, will welcome, on behalf of the University, the members of the association at the opening of the conference Papers will be read by Rev. W Hardy Harwood (Chairman of the Council) and Principal J F Hudson (Huddersfield) on "The Relation of Technical Education to the Question of General Education." Principal J. Quick, on "Central Schools and their part in the Preparation of Scholars for Higher Technical and Junior Technical Schools," and by Mr. E. C. Kyte, Secretary of the Library Association, on "Technical Libraries—How to Start and Develop them."

THE annual report of the Livesey Professor, Prof. John W. Cobb, at the University of Leeds, gives an account of the work done in the department of coal gas and fuel industries (with metallurgy) for the session 1920–21. The number of students (41) reached the highest figure in the history of the department, one third (14) taking the fuel and metallurgy course, the remainder (27) the course in fuel and gas engineering. The special evening classes included courses on the distribution of gas (Mr. Walter Hole), coke oven practice (Mr. W. Greaves), steaming in vertical retorts (Dr. A. Parker), and metallurgy (Mr. P. F. Summers). These courses were attended by 49 external students in addition to the full-time registered students. Researches were carried out on the liberation of nitrogen from coal and coke as ammonia, the structures of cokes prepared at different temperatures, the losses of ammonia in coke oven practice, a laboratory apparatus for coal distillation, the expansion of refractory materials, the trustworthiness of recording gas calorimeters, and the efficiency of production of blue water gas. The endowment funds of the department have benefited by substantial donations from the South Metropolitan Gas Company, the South Suburban Gas Company, and from Mr. A. G. Glasgow.

Societies and Academies.

LONDON.

Royal Society, June 15.—Sir Charles Sherrington, president, in the chair.—H. M. **Evans**: The defensive spines of fishes, living and fossil, and the glandular construction in connexion therewith, and observations on the nature of fish venoms. The gland in the groove of the spine of the sting-ray (*Trygon pastinaca*) consists of two portions—the deepest part of the groove contains an alveolar-connective tissue structure, which is separated from the true glandular epithelium by a pigmented capillary layer. The dorsal fin-spines of the spiny dog-fish Acanthias are grooved, and the groove is occupied by a gland with definite follicles. Cestracion also has a well-developed gland at the base of the dorsal fin spines. The spines of Chimæra and of the Pleuracanthidæ show structures which suggest a specialised function. The nature and properties of Weever venom are described; the filtration of venom profoundly affects its hæmolytic properties. Experiments are described on the native use of abrin as an antidote to fish venoms.—D. W **Cutler**, L. M **Crump**, and H. **Sandon**: A quantitative investigation of the bacterial and protozoan population of the soil: with an account of the protozoan fauna. The results of 365 consecutive daily counts of the numbers of bacteria and of six species of protozoa in a natural field soil are given Large fluctuations occur which cannot be correlated with meteorological conditions. Fourteen-day averages of the daily numbers show marked seasonal changes superimposed on the daily variations in numbers. In general, both bacteria and protozoa are most abundant at the end of November, and fewest during February. The changes are not directly influenced by temperature or rainfall. An inverse relationship is found between the numbers of bacteria and certain amœbæ, and a two-day periodicity obtains for the numbers of the flagellate *Oicomonas termo* which are active.—D W **Devanesen**: The development of the calcareous parts of the lantern of Aristotle in *Echinus miliaris*. All the calcareous elements of the lantern of Aristotle, with the exception of the teeth, are deposited as triradiate spicules. A "compass" arises from two rudimentary spicules It is the only element of the lantern absent in the "echinus-rudiment." A tooth is a paired structure in consequence of its composition of a double row of lamellæ. A pair of lamellæ is its ultimate unit. A remarkable stage in the consolidation of these lamellæ is the cone-in-cone arrangement. The carina is formed by the beaks of the serially fitting cones The ossicles of the lantern are compared with those of the mouth-frame of star-fish.—A. **Lipschütz**, C. **Wagner**, R. **Tamm**, and F. **Bormann**: Further experimental investigations on the hypertrophy of the sexual glands.

Zoological Society, June 13.—Prof. E W. MacBride, vice-president, in the chair.—Miss J. B. **Procter**: A study of the remarkable tortoise *Testudo loveridgii* Blgr., and the morphogeny of the Chelonian carapace.—J. T. **Carter**: A microscopical examination of the teeth of the primates.—H. G. **Jackson**: A revision of the isopod genus Ligia, Fabricius.—W. R B **Oliver**: A review of the Cetacea of the New Zealand seas.—F. Wood **Jones**: On the dental characters of certain Australian rats.

Linnean Society, June 15.—Dr. A. Smith Woodward, president, in the chair.—A. B. **Rendle**: Seedlings of horse-chestnut from which the terminal bud had been removed by cutting through the epicotyledonary stem. Minute buds appeared on the cut surface corresponding in position with the cambium-

layer in the stem. A new shoot was also produced in the axil of each of the cotyledons.—Sir Arthur Shipley: *Furia infernalis.* Linnæus was probably stung by a virulent insect which may have conveyed to his system some pathogenic germs unknown at that time.—T. A. Sprague: The identification of *Sison Ammi*, Linn. *Sison Ammi* is an umbelliferous plant published by Linnæus in the first edition of the "Species Plantarum" in 1753. The type-specimens in the Linnean Herbarium and the British Museum show that it is *Carum copticum*, a medicinal plant which yields the Ajowan seeds and Ajowan oil, from which thymol is obtained. The history of the drug Ammi goes back to Dioscorides, who lived in the first century of the Christian era, he described it as having a minute seed with the flavour of marjoram. Various plants have been described as the Ammi, but in the plates of Umbelliferæ published by Rivinius at the end of the seventeenth century, the officinal Ammi is *Carum copticum*. The geographical source of the drug supports this conclusion. The best quality of Ammi was imported from Alexandria, but was actually grown in Arabia, where *Carum copticum* is still cultivated It has never been found in a wild state.—E. A. Newell **Arber**: Critical studies of coal-measure plant impressions The British Upper Carboniferous species of the genus Lepidostrobus, Brongn, preserved as incrustations, and other impressions were discussed.—J. **Burtt-Davy**: A revision of the South African species of Dianthus. Thunberg's specimen of *D. incurvus*, Thunb., does not match any South African material at Kew or the British Museum. Thunberg himself identifies it on the sheet with *D. albens*, Ait, but the specimen does not agree with the type of *D. albens* in the British Museum. In the "Flora Capensis," Sonder recognised nine species of Dianthus. Of these, seven only are valid, and to them must be added four species not recognised by Sonder Six additional species and three varieties are now described, bringing the total number up to seventeen species and three varieties

Royal Meteorological Society, June 21—Dr. C Chree, president, in the chair—J. E. **Clark**, H. B **Adames**, and I. D. **Margary**: Report on the phenological observations for the year 1921. After mid-December the mildness until late March was extreme, which gave premature fruit blossom and its usual concomitant of poor fruit crops, except apples The four early spring flowers were more than 18 days earlier than the 30 years' mean, April and May, 14 days, June, 10, and July, 6 days Grain-cutting was very early. The warm thrush along the Bristol Channel, and up the Severn and Dee valleys to include the Wirral Peninsula, was almost identical with the isophenal trend and values for 1920. In the north-east of Norfolk there was a recurrence of the cold area so well marked in the years 1919 and 1920, spreading southward from the North Sea, and curving south-eastward by Norwich to include Bungay, and also of the long tongue stretching from the Scottish border southward to include Leicestershire and Rutland. The northerly bulge of warmth just north of the Isle of Wight was again very definite. High ground is, as before, indicated on the maps by relatively late isophenal areas. Among exceptional effects were the brief blooming period of the summer flowers and the earliness of the autumn flowers, especially the Michaelmas daisies; the dormant or destroyed seed-sowing experiences; the frequency of second blossom after the August rains, typically the horse-chestnut; the early departure of the swallows; the dearth of tortoiseshell and allied butterflies, apparently from lack of nettles. October had a week of unparalleled heat, while November opened with severe frosts. After a partial fall in late July, trees had retained their foliage to an unusually late date, and those frosts had the effect of making many of the leaves brown and shrivelled as if from excess of heat. Planes and elms kept their green leaves almost or quite until December.—L. F. **Richardson**, A. **Wagner**, and R. **Dietzius**: An observational test of the geostrophic approximation in the stratosphere. Wind velocity, at points not too near the earth's surface or the equator, may be found with an accuracy of about 5 per cent. from the horizontal pressure gradient and the rotation of the earth. A test of the error involved in neglecting other considerations is obtained by inserting the "geostrophic" velocities in the equation for the accumulation of mass. Thus a theoretical equality, valid in the stratosphere, between certain derivatives of wind and temperature is obtained. From observations collected by Wagner and Dietzius, the quantities which this theory makes equal have a positive correlation of about four-tenths.

EDINBURGH.

Royal Society, May 8.—Prof. W. Peddie, vice-president, in the chair.—Prof. E. T. **Whittaker**: The quantum mechanism in the atom (see p. 23).—A. R **Forsyth**: Differential invariants and other concomitants of quadratic differential forms in four variables. The method is that of Lie's continuous groups, and is thus entirely different from the Christoffel method usually expounded. It provides new results which the Christoffel method did not even suggest It can be applied to obtain Einstein's critical form in the relativity theory of gravitation; on one hand, some of his conditions were covered by others, and on the other hand his form satisfied one equation more than the set he initially postulated.—T. R **MacRobert**: The asymptotic expansion of the confluent hypergeometric function, and the Fourier-Bessel expansion.

PARIS.

Academy of Sciences, June 6.—M. Emile Bertin in the chair.—Ch **Boulanger** and G. **Urbain**: The composition and chemical characters of thortveitite from Madagascar. Five complete analyses of this mineral are given. The proportion of yttrium earths does not exceed 0·5 per cent., while the Norwegian mineral contains 4-18 per cent. Of this group only yttrium, neoytterbium, and lutecium could be detected—MM. **d'Arsonval**, **Bordas**, and **Touplain**. Study of the glacier waters of Argentière and Bossons. There are marked differences in the electrical conductivity and chemical composition of the waters from these two sources.—Carl **Størmer**: Determination of the external magnetic field of the sun by the structure of the solar corona and the constants of the aurora borealis.—Louis **Roy**: Electromagnetic actions in an isotropic system.—G **Reboul**: A new radiation and its application to the study of the ultraviolet of Millikan and Lyman.—A. **Tian**: Thermostats with multiple jackets. The copper vessel containing the liquid to be maintained at a constant temperature, is surrounded with felt and placed in one or more boxes, also of copper, which are isolated in the same manner. The external jacket is heated, and a uniform, steady temperature can be thus maintained without stirring. The advantages claimed for this system are that the thermal oscillations due to the regulator are almost entirely eliminated. The temperature of the inside bath is practically independent of variations in the room temperature, and stirring is not required.—Léon and Eugène **Bloch**: Spark spectra in water.

The photography of spectra of sparks under water, by the automatic separation into arc lines and spark lines and by the differences in the appearance of the lines, appears to be valuable in detecting spectral regularities.—M. de **Bellescize**: Damping the oscillations of resonators in wireless telegraphy.—A. **Recoura**: Some new properties of the green sulphate of chromium. Green sulphate of chromium forms complex compounds with potassium sulphate, and the resulting solutions give reactions with benzidine compounds or with barium chloride, indicating that SO_4 ions are absent or present in small proportions only. Results are given of a study of the effects of temperature, dilution, and time on these complexes.—Paul **Riou**: The velocity of absorption of carbon dioxide by alkaline solutions.—Mlle. **Wurmser**: The preparation of ammonium nitrate. An extension of earlier work by M. Rengade on the formation of ammonium nitrate by the interaction of sodium nitrate and ammonium chloride.—Mlle. N. **Wolff**: Furfural-α-methylcyclohexanone and some of its derivatives. Mono- and difurfuralcyclohexanones.—E **Berger**: A formal lamp. A detailed account, with diagrams, of the construction of a new lamp for burning methyl alcohol to formaldehyde. With copper oxide as a catalyst the yield is 25-30 per cent. with silvered asbestos, 35-45 per cent. of the alcohol used is obtained as formaldehyde. Results of the application of the lamp to practical disinfection of rooms are given.—H. **Joly**: The tectonic direction of the Cretaceous and Tertiary deposits in the neighbourhood of Haro (Logroño, Spain).—P. **Lory**. The glacial stages and a valley recording these stages (Bédinat, Chaîne de Belledonne).—P. L. **Mercanton**. The glacial system of the Beerenberg of Jan Mayen This extinct volcano was climbed by the author, with J. M. Wordie and T. Lethbridge, in August 1921. From the highest point (about 2500 metres) the structure of the crater was made out, and a detailed account of this and the glacier system is given.—MM. **Pons and Rémy**: The reddish-brown coloration shown in March **1922** by the Briançon snow Specimens of the coloured snow, collected on March 19 at an altitude of 2350 metres, were examined, after melting, chemically and microscopically. There was practically no organic matter, and the microscope showed no remains of microscopic organisms (Algæ, Foraminifera, diatoms), nor were there any vitreous inclusions characteristic of volcanic dust. Chemical analysis showed silica, iron, and alumina The possible origin of the dust is discussed, but no definite conclusion could be arrived at.—P. **Bugnon**: The fibrovascular organisation in Mercurialis. Possible descent from a primitive form.—Gustave **Chauveaud**: The principal variations in the vascular development of the first phyllorhiza of Phanerogams are not determined by intercalary increase.—Louis **Lapicque**: Mechanism of the exchanges between the cell and the surrounding medium The osmotic pressure in the cells of marine Algæ is higher than that of sea water. This is incompatible with the currently accepted view that all exchanges of the cells are determined by the laws of osmosis. The author holds that, on the contrary, the exchanges of the cells are the result of physiological work and that diffusion and osmotic pressure intervene often as resistances only.—Paul **Portier** and Marcel **Duval**: The variation of the osmotic pressure of the blood of the cartilaginous fishes under the influence of modification of the salinity of the surrounding sea water. The dog-fish was used in these experiments, and it was found that the osmotic pressure of the blood was not equal to that of the sea water in which the fish is immersed. There was a tendency for the osmotic pressure of the blood to follow that of the sea water, but the adjustment was very imperfect. The fish supported dilution of sea water better than enrichment with salt.—E. **Fauré-Fremiet** and Mlle. H. **Garrault**: Constitution of the ovarian egg of the carp (*Cyprinus Carpio*).—H. **Vallée** and H. **Carré**: The plurality of the aphthous virus.

Brussels.

Royal Academy of Sciences, June 3.—M. A. Lameere in the chair.—F. **Swarts**: On trifluormethylcyclohexane.—F. **Swarts**: On trifluoracetic acid.—Th. **De Donder**: The electromagnetic field and the gravific field.—A. **Mélant**: The conditions determining the encystment of the infusorian, *Euplotes harpa*.—M. **Philippson**: A new form of electrical resistance of electrolytes.—M **Nuyens**: A change in the variables of M. De Donder.—P. **Bruylants** and J. **Dondeyne**: The determination of the atomic weight of selenium.

Metric and British Measures.

IN view of the vigorous and sustained efforts of the exponents of the metric system, and the eminent names that are to be found among them, it is perhaps not a little surprising that it makes so little progress towards general acceptance in Great Britain. The Weights and Measures Act of 1897 legalised the metric denominations for use in trade, and was expected to lead to its advantages being so generally recognised that the Imperial system would soon disappear. Twenty-five years have now elapsed, and the position is almost unchanged. In fact, the policy of compulsory introduction of the metric system by law, which formerly was always strongly supported, was ruled out by the Metric Committee of the Conjoint Board of Scientific Societies in its Report in 1919, and though the report of this Committee was not adopted by the Board, the subject of compulsion is not likely again to be seriously considered for some time at least. Even the Decimal Association has recognised this position, and now advocates a modification of the Imperial system which will serve as a first step towards facilitating the ultimate end it has in view. A modification of some sort is now being called for with increasing insistence, so that it may be desirable to examine the principal considerations involved.

A fundamental distinction must, at the very outset, be drawn between the importance of stability in the units of quantity and of dimension respectively. The units of mass and capacity, speaking generally, serve simply for determining a certain quantity of goods, and the margin of tolerance is usually fairly large; and even if this margin is greatly exceeded, the loss, to one or the other party to the transaction, is the value represented by the amount of the error alone. An alteration in the magnitude of these units, therefore, if not very large, would pass almost unnoticed. Material weights, and to a certain extent measures also, can be adjusted without any great difficulty, though the recalibration of weighing machines would not be quite so simple. The unit of length is of a different character. Size, which determines the interchangeability of parts and fittings, is not capable of ready adjustment, and an error in dimensions often involves the waste of the whole article. A change from one unit to another, not commensurable with it, must therefore introduce serious difficulty, in that apparatus designed to suit one unit cannot easily be adapted to be of service under the other. The only kind of change which could be accepted without much inconvenience would be one which left the new unit expressible, in the terms of the old, by a simple ratio, the absolute change of magnitude being of minor

importance. It was this point which went far towards determining the general trend of the Report of the Committee of the Conjoint Board.

The present policy of the Decimal Association must be examined with this difference in mind. The Association suggests a step-by-step transition, leading to a gradual familiarisation of the country with metric units, until the opposition is so far reduced that a compulsory metric system Act becomes possible. As a first step, the pound avoirdupois is to be readjusted so as to become exactly equal to half a kilogram—an increase of about 10 per cent. The official policy of the Association is to alter the ounce, dram, and grain similarly, retaining their present ratios. Dr. Guillaume prefers, if there is to be a "piecemeal" policy, to make the new pound (500 grams), contain 20 ounces, 250 drams, and 10,000 grains, the percentage changes in magnitude being of about the same order, but not all in the same direction.

It will be seen that, in itself, a change of this sort could probably be made without serious difficulty, if it were thought to be necessary. That is to say, if a deliberate and agreed decision had been come to that the metric system exclusively was to be employed in Great Britain, the transition might well have been begun in this way. In the absence of such a decision, the position is less clear. A certain amount of inconvenience must inevitably arise, particularly in the introduction of a new series of weights and measures in retail trade; and although the ultimate introduction of the metric system might be facilitated by the proposed modification, it is scarcely likely that those who are opposed to the end in view will offer any less opposition to the means employed. Faced with the ultimate proposal, that the inch should be altered to constitute one-fortieth of a metre - and this is probably the least objectionable line of action open—no concession is to be expected from opponents in favour of a first step, which does not, in itself, present very obvious advantages. It is probably far too seldom realised that the great objection to the metric system is based upon the incommensurability of the British and metric units of length. The real battle lies between the inch and the centimetre. If the alteration of either, to make it commensurable with the other, could be admitted, then its ultimate abolition could follow without much difficulty.

The view is quite widely held that the Imperial units are, as magnitudes, more suitable for commercial purposes than the metric. There is, therefore, at least a possibility that the solution of the metric controversy may be found in the development of a system based upon the British units, but so modified as to be capable of treatment on pure decimal lines. The Report of the Committee of the Conjoint Board suggests that the possibilities of such a solution should be explored, and one experiment in this direction has already been tried with success. The troy pound was abolished in 1878, but the troy ounce was too firmly established to be dismissed entirely. Trade in the precious metals, however, is now carried on in terms of troy ounces only, and bullion weights are made up solely in decimal multiples and sub-multiples of that unit. There has certainly been some activity in this direction in recent years, and should a really logical system upon a decimal basis be devised and secure general acceptance in the countries now using Imperial units, it may be found that these units are, after all, destined to survive.

Influenza.

Influenza: Essays by several Authors. Edited by F. G. Crookshank. Pp. xii+529. (London: W. Heinemann (Medical Books), Ltd., 1922.) 30s. net.

A VALUABLE series of essays is given in this volume, bringing our knowledge of this devastating disease up-to-date, and at the same time demonstrating the nebulous character of this knowledge and our impotence in face of its recurring pandemics. From the wider point of view the contributions of Drs. Crookshank and W. H. Hamer are especially valuable. The seven chapters contributed by Dr. Crookshank would have been even more valuable than they now are, had he condensed them and treated his subject more systematically. They bear evidence of previous separate publication, with considerable repetition and occasional laxness in sequence of matter.

The rest of the volume is occupied by chapters on the clinical and therapeutic aspects of influenza, which need not detain us, and by a chapter of 175 pages dealing with the bacteriology of influenza, which would have gained greatly by severe condensation.

The chief interest of the volume, however, consists in a full statement of the special views respecting influenza which the lucid and skilful writing of Dr. Hamer, ably seconded by Dr. Crookshank, has rendered important; and every one wishing to study the epidemiology of influenza, and to learn another view than that apparently favoured in the official report of the Ministry of Health, will need to study these chapters carefully.

The question at issue is whether influenza, in the various forms which are usually recognised as this disease, is a single specific disease, due to a special contagium, which may or may not be the Pfeiffer bacillus; or whether the same virus may not also be the cause of "phases" of influenza, including cases

in which the nervous centres are seriously affected, and in which the varieties of disease included in the Heine-Medin symptom complex occur.

Dr. Hamer evidently looks to a filter-passing organism as the likely key to the position, and avers that "most of the 'causal organisms' of bacteriology can be shown to be mere upstart associated organisms or secondary invaders." Using Dr. Crookshank's conception that three fundamental factors are concerned, namely, the disease, the epidemic, and the epidemic constitution, Dr. Hamer advocates the hypothesis that *the* cause of the disease, of the epidemic, and of the epidemic constitution "is the mutating *vera causa* or primary influence," which may be some ultra-visible organism. Much stress is laid on the epidemics which commonly precede and follow, or are associated with, typical influenza. Dr. Hamer evidently thinks that much of the trench fever in the recent war was influenza. This may be so, in a proportion of the cases in which an error of diagnosis was made; but this would not apply to the cases of true trench fever, the communicability of which by body lice has been demonstrated. A reference to Malta fever is similarly confusing; for if this is to be regarded as belonging to the large influenzoid group, it is remarkable that it should be entirely preventible by boiling all goat's milk which is consumed by human beings. In Dr. Hamer's words, "in thickly inhabited areas of the globe a kind of law of coincidence or of overlapping of cerebro-spinal fever and poliomyelitis and pandemic influenza" is visible. This relationship it is maintained is "not simply and solely one of concurrence, but of regulated development in definite sequence," and Creighton, our leading historical epidemiologist, is quoted in favour of the contention that we must keep in mind "gradations, modifications, affinities," and be "careless of symmetry, of definitions or clear-cut nosological ideas, or the dividing lines of a classification."

With this general proposition we are in accord, and we may agree also that fixity of type of epidemic diseases and their causal organisms is not to be assumed; but, taking the three diseases just named, it requires much imagination even to assume that they can all be due to variants of a common infection. Our knowledge of the infecting agent in poliomyelitis is now considerable; and although the proof that the meningococcus is the cause of cerebro-spinal fever is not absolutely complete, the converging evidence of bacteriology and vaccinal treatment is strongly in favour of this conclusion. Without adequate reason, to assume that the contagia of diseases which are commonly associated are variants of a common contagium is a retrograde scientific step; it appears much more probable that the true explanation of the frequent association or sequence of influenza, poliomyelitis, encephalitis lethargica, and cerebro-spinal fever is that the "epidemic constitution" in these years favours the whole group of infections and not merely one of them—influenza. There is close analogy between this view and the view which explains the coincidences and sequences in seasonal and pandemic occurrence of scarlet fever, puerperal fever, rheumatic fever, diphtheria, to which attention has been directed in investigations by Longstaff and Newsholme. It can scarcely be contended that all these diseases are manifestations of a common infecting agency.

The view just stated appears to be confirmed in the article in the present volume by Dr. Dwight Lewis of Newhaven, U.S.A. Classical influenza, in his view, is caused by the Pfeiffer bacillus, but "the various waves of the so-called pandemic of influenza were caused by consecutive and increasing prevalences of correlated diseases due to the activation of carriers of the organisms of these diseases, whether by the influenza bacillus or by the streptococcus." There is no difficulty in believing in what we may call a first-cousinship of diseases, in the influence of one or other of these in increasing the virulence of another, and especially in believing in the death-dealing quality of their combined operation, as, for example, that of the organism of influenza and of the *Streptococcus hæmolyticus*.

The criticisms in the last chapter of the Government report on influenza are interesting. There is just enough truth in the statement that "what is not recorded, or is not known to be recorded, does not officially happen," to give it tang.

Dr. Crookshank appears to differ gently from Dr. Hamer in the description of the intercurrent maladies as "phases of influenza," and suggests that these "specialised" epidemics should be described as *influenzoid*. With considerable imagination, he suggests that the recognition of these would be the first step towards the foretelling of the imminence of pandemic influenza. If this ever become practicable, it will constitute an important advance in our knowledge; but meanwhile we are all familiar with sporadic cases of these diseases which are not followed by epidemic influenza.

In short, this contribution to the subject is provocative of thought; and we hope also that it will lead to more exact epidemiological as well as bacteriological investigation. It presents a better philosophy of epidemicity than is usual; and Dr. Crookshank's contributions on this aspect of the problem will repay study. We rather think, however, that he is somewhat astray in apparently thinking that the importance of "epidemic constitution"—as a factor in producing pandemicity—is not generally recognised. This is the

mystery of mysteries, and we have not yet approached its solution. But we must approach it; for recurring pandemics of influenza like the recent one are more serious to civilised mankind than even the Great War.

History of Electrotherapy.

An Essay on the History of Electrotherapy and Diagnosis. By Hector A. Colwell. Pp. xv+180. (London: W. Heinemann (Medical Books) Ltd., 1922) 17s. 6d. net.

AN essay of 171 pages indicates a healthy respect for the subject treated and this is handed on to the reader who peruses it. Dr. Colwell has in some ways been fortunate in his subject, because it is one which yields to historical treatment when approached by a scholar. Of the evidences of this latter quality there is plenty of proof throughout this essay; there is a happy blending of historical accuracy, judgment in selection of facts, and a sense of the real importance of the subject of electrotherapy. The parent subject is now rather apt to be somewhat eclipsed by the more youthful one of radio-therapy, yet the benefit derived from electro-therapeutic measures in diagnosis and in the treatment of many diseases is a matter which need not be laboured.

Perhaps more than in any other branch of the healing art, the scientific advance of the subject to its present position has been one long series of spasmodic efforts interspersed between long periods of quiescence and indeed neglect. The neglect was probably the rational outcome of the conditions of quackery which often showed itself in the application of electricity to the ills of the human body. It is probably not very far from the truth to correlate this halting progress of the subject with the parallel state of affairs in the study and researches of a physical character into the nature of electricity itself.

It is interesting to read that a professor of physics, one Jallabert of Genoa, is to be regarded as the first scientific electrotherapist, for it is a matter of history that, in 1747, in collaboration with the surgeon Guyot, the electrical current was employed by him to produce muscular contractions in injured limbs, thus giving them the exercise necessary for the restoration of their normal functions. Though this is the case, the founding of modern electrotherapy occurred almost a century later as a result of the work of Duchenne of Boulogne.

The essay traces the growth of the subject to the present day. The last forty pages are devoted to the subject of radiology, but perhaps the lapse of time since the discovery of X-rays has been insufficient for a successful treatment of the subject on historical lines. Four pages of notes and an index complete a volume which is very well produced and illustrated by a number of plates of great individual interest.

The auther is to be congratulated on an essay which marks out so clearly the milestones which have been passed and the obstructions which have been met in the journey of electrotherapy to its present-day status.

Mustard Gas Poisoning.

The Medical Aspects of Mustard Gas Poisoning. By Prof. A. S. Martin and Dr. C. V. Weller. Pp. 267. (London: Henry Kimpton, 1919.) 42s. net.

THIS volume is a belated account of investigations carried out at Michigan during the war; in 1917 it would have been eagerly welcomed, at the date of publication which it bears it would have been decidedly interesting, at the present time it will only be so to specialists and historians. It tells, with a wealth of detail which seems needless, of the effects of β-β-dichlorethyl sulphide, or mustard "gas," on various animals and on men accidentally gassed with it at factories in America where the substance was manufactured for gas offensive purposes during the war.

The substance is a general protoplasmic poison, readily penetrating the epidermis and other tissues; once inside the cells it is probably hydrolysed, and the extensive damage is due to local liberation of hydrochloric acid. The chief effects are therefore a destruction of all the cells with which the substance comes into contact; the eyes, lungs, and skin are the most likely to be affected, and the danger lies chiefly in the fact that the substance has but little smell, so that dangerous concentrations may be encountered without arousing suspicions in those unacquainted with the properties. As the substance is a liquid of high boiling-point, soil or other materials which have been fouled with it may remain a source of danger for days.

Treatment of the affected parts is directed chiefly to the alleviation of symptoms; chlorine destroys the substance, so that local application of hypochlorites is useful in the treatment of skin burns, which are the most troublesome effects likely to be met with in men whose eyes and lungs are protected by the wearing of respirators.

The reviewer himself worked out the chief physiological effects of this substance on animals in the spring of 1916, at the suggestion of his colleague Dr. H. W. Dudley; the results were reported through the proper channels, but were not published. The Germans first used the substance some fifteen months afterwards.

The work before us is the most complete and accurate

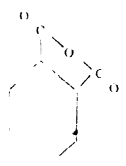
account of the subject of mustard gas poisoning extant. Let us hope that it will be long before such a book is needed again; should there be another big war in our time, this work will provide a complete account of the properties of a substance which, had it been used earlier in the recent war, would almost certainly have proved a deciding factor.

C. LOVATT EVANS.

Tinctorial Chemistry and Histology.

Untersuchungen uber Echtfarbung der Zellkerne mit künstlichen Beizenfarbstoffen und die Theorie des histologischen Farbeprozesses mit gelosten Lacken. Von Prof. Dr. Siegfried Becher. Pp. xx+318. (Berlin: Gebruder Borntraeger, 1921.) 10s. 6d.

THERE have been several attempts to evolve a scientific basis of the staining processes which are used in histology, but nothing as comprehensive as the book under review has so far been produced. It is the outcome of more than twenty years of research on the application of tinctorial chemistry to histology. The book contains a remarkable amount of sound chemistry, and one cannot but wonder how a professor of zoology and comparative anatomy could have found the time to acquire such profound knowledge of a subject so removed from his special lines of thought and study. Dr. Becher has been very successful in the manner in which he has combined histology with chemistry, and even the few peculiarities in his chemical terminology and chemical formulæ, such as, for example, his eccentric formula:



for phthalic anhydride, only add to the peculiar charm of the book. They vouch, at least, for the fact that the author has not blindly copied his chemical matter, which is too often the case when biologists develop chemical tendencies.

That the rituals of histology will have to give place to chemical common sense is evident from Becher's researches, which show conclusively that successful staining depends on one factor only, namely a well selected "triple-alliance" (a *bon mot* presumably chosen by Dr. Becher before the War) of tissue, mordant, and stain. Careful considerations of the individual and combined chemical properties of these three factors lead to success, their neglect spells failure. This is the *leit-motif* of the whole research, which is abundantly supported by more than 2000 experiments. Becher's researches lead him also to the following generalisations, namely (1) the solubility of the "lakes" (metallic compounds of organic colouring matters) is of great importance, for good staining depends not on the solubility of the dye, but on that of the "lake," and (2) that all "lakes" of the hydroxy-anthraquinones are of general use for nuclear staining. The hydroxy-anthraquinones have been specially studied by Becher and the attention of histologists may be directed to pp. 271-275, which give a practical summary of these results.

However, not only histologists, but also chemists will find much in this book that will be of interest to them. There is too much belief in the infallibility of Grubler's stains in histological circles and the British dye industry would, perhaps, be well advised to pay some attention to this particular aspect of tinctorial chemistry. That not only Germany but also other countries manufacture dyes which give good histological results is again also evident from the work under review, since Dr. Becher has successfully used French, Swiss, Dutch, Belgian, and British dyes.

Reference might, perhaps, be made to a few minor errors, such as the statement on p. 121 that ellagic acid was synthesised by Georgievic in 1913, whereas it was actually synthesised by Perkin and Nierenstein in 1905. Such slight defects, however, detract little or nothing from the value of the book, which is certainly the best of its kind so far published.

M. NIERENSTEIN.

Mineral Resources of Yugoslavia.

The Geology and Mineral Resources of the Serb-Croat-Slovene State. Being the Report of the Geologist attached to the British Economic Mission to Serbia. By D. A. Wray. (Department of Overseas Trade. Ref. No. F.E. 383). Pp. 111. (London: H.M. Stationery Office, 1921) 3s. 6d. net.

THE Department of Overseas Trade has rendered a distinct service to economic geologists in publishing an account of the mineral resources of Yugoslavia, because our knowledge of this subject has hitherto been decidedly fragmentary. A few of the mineral deposits have long been well known, such as the mercury mines of Idrija, the copper mines of Majdanpek and the iron mines of Vares, but systematic information was lacking and this has now been supplied by the painstaking work of Mr. D. A. Wray.

After a brief introduction dealing with the more important general and economic features of the new

state of Yugoslavia, we have first a brief but clear account of the geological structure of the region under discussion; it is greatly to be regretted that this part of the work was not illustrated by a geological map of some kind, even though it were only a small sketch map, as this would have been extremely helpful for a proper understanding of the somewhat complex geology. The various mineral deposits are next described in much detail, this constituting the principal and indeed the most valuable portion of the work. Under the heading of coal it is shown that true bituminous coal is very scarce, but that there are considerable reserves of lignites, which amount probably to about 1900 millions of tons, whilst the possible reserves are even greater. With the exceptions of some of the smaller beds of Liassic and Cretaceous coal in Serbia, all the coals are of Tertiary age and are for the most part of inferior quality, their calorific power lying usually between 4000 and 5000 calories. They can, however, be used successfully on railways, for steam raising and for domestic purposes, but are not suited for metallurgical operations or other work where high temperatures are required. Apparently the coal resources of the State would cover satisfactorily the great majority of its requirements, were it not for the grave lack of means of communication, which also has hindered in no small degree the development of the various coal-fields.

There are quite a number of deposits of iron ore; according to Dr. Katzer, the Government geologist, the more or less known reserves of iron ore amount to some 22 million tons, of which 15 millions are limonite. Mr. Wray is of opinion that "the total reserve tonnage may safely be computed at 30 to 40 million metric tons." The iron industry is, however, quite insignificant; there are a few small blast-furnaces, chiefly in the Vares district, charcoal being apparently the only fuel used; one of these furnaces, situated at Krapuli, 2 kilometres south of Vares, is said to have a daily output of more than 100 tons of pig iron, probably the largest ever obtained from a charcoal furnace. Owing to the want of good coking coals and the defective means of transport, there seems at present little probability that this industry can attain dimensions of any importance.

There are well-known copper mines at Majdanpek, which have been worked since Roman times; the output from 1870 to 1890 is stated to have totalled about 2500 tons of copper. Another important group of mines is that of Bor, now being worked by a French company; the production is said to have gone up to the high figure of 7575 metric tons of copper in the year 1911–12. The famous quicksilver mines of Idria have been worked ever since the fifteenth century, the annual output since 1900 having been of the order of 500 tons.

Among the other minerals that have been or are being worked may be named iron pyrites, manganese ore, chrome ore, antimony ore, gold, lead ore, zinc ore, bauxite, meerschaum and rock-salt.

It will be clear that Mr. Wray has done his work extremely well and has collected a great bulk of very valuable information. It is, however, to be regretted that he did not submit his proofs for revision to some competent metallurgist, as several blunders forming serious blemishes in the report would in this way have been detected. For instance, Mr. Wray states that there are at Majdanpek "three furnaces of the 'Knudsen' type (Sulitelma and Co., Norway)," whereas the Knudsen process is conducted in a special form of converter, and was worked out by the inventor at the well-known Sulitelma mines. Again, his description of the "Majdan" furnaces, evidently a primitive form of blast-furnace, is quite unintelligible; he writes: "The pig-iron came out in part with the scoriæ, and in part remained in the bottom of the furnace. The latter product was much preferred, as by the continual action of swiftly-moving hammers (driven by water-power) it lent itself directly to treatment." It is obvious that if this material was pig-iron, it could not have been worked under the hammer, and we are left in doubt whether it was malleable iron or steel, or whether it really was pig-iron which was converted into malleable iron in some kind of a finery; either of these might be the correct explanation, whereas the statement as it stands is obviously incorrect.

H. L.

Hydraulics.

Hydraulics with Working Tables. By E. S. Bellasis. Third Edition. Pp. viii + 348. (London: Chapman and Hall, Ltd., 1920.) Price 18*s.* net.

HYDRAULICS is largely an empirical science and as experience accumulates it is to be expected that the formulæ expressing the flow of water in particular conditions will be modified either in form or by a change in the experimental coefficients. The author of the book before us has had considerable experience in the irrigation department of India, and it might have been expected, therefore, that new data confirming or modifying generally accepted formulæ would have been incorporated; particularly additions to knowledge in those cases in which the experimental work has been small might have been forthcoming in this work. We look in vain, however, for such new data; the author has been content to discuss certain principles, to accept the generally accepted formulæ and to illus-

trate their applications in connexion with important practical problems. To determine the flow in pipes and channels the author adheres to the old Chezy formula and gives tables of values of the coefficient C. He not unreasonably points out that this formula has the advantage of simplicity over the logarithmic formulæ, but he does not adduce evidence from his experience as to the comparative accuracy of the results they give. Thus the serious student of hydraulics can scarcely be satisfied with the treatment.

The chapter dealing with variable flow in open channels is of considerable interest and importance, and contains valuable suggestions to those who deal with such channels, especially when the streams are dammed by weirs and barrages. The correct form of the surface up stream from such barrages is, however, not satisfactorily discussed; the problem is admittedly a difficult one, but of importance, and needs more adequate treatment than that given by the author.

The brief chapter on unsteady flow deals with the time of emptying vessels and with waves in open channels; there are also brief remarks on the effects of waves and floods assisting in scouring or causing deposits. The work concludes by a brief chapter on the dynamic effect of flowing water.

The student will find this work suitable for reading in conjunction with some work on hydraulics which deals with the subject from the fundamental rather than from the practical engineer's point of view. The development in the volume under notice is not sufficiently logical for the student desirous of understanding thoroughly the fundamentals of the subject, but he as well as the practising engineer will find it both useful and interesting. F. C. L.

Our Bookshelf.

Applied Entomology: An Introductory Text-book of Insects in their Relations to Man. By Prof. H. T. Fernald. (Agricultural and Biological Publications.) Pp. xiv + 386. (New York and London: McGraw-Hill Book Co., Inc., 1921.) 21s. net.

TEXT-BOOKS of applied entomology are usually compiled according to one of two methods. In one type of book the various injurious insects are classified and enumerated under their respective orders and in the other type they are dealt with under the crops or other objects with which they are associated. The first method, which is the one adopted by Prof. Fernald, is unquestionably the better way of presenting the subject to the elementary student. The alternative method is more adapted to the needs of a practical reference book, in which the primary consideration is to render the information available by means of the most convenient, although not necessarily the most scientific, manner of presentation.

Prof. Fernald has carried out his task with conspicuous ability, and the book is certainly worthy of the Massachusetts school of entomology. Within a compass of less than 400 pages he manages to give the essential facts concerning the biology and control of all the more important insects affecting man, either directly or indirectly, in the United States. The general introductory chapters are perhaps a little too much abbreviated; nevertheless, they contain the essential elementary facts concerning the structure and metamorphoses of insects, and the principles of control commonly in vogue. Twenty-four orders of insects are recognised, and each is dealt with in turn, whether it contains injurious species or not. The student is thus enabled to view the class Insecta more or less as a whole, and appreciate the place of each order in the scheme of nature. The work is adequately illustrated and well printed. A few misprints are noticeable in the explanatory text relating to eight or nine of the illustrations, but they are not sufficiently serious to detract from the value of the book. A. D. IMMS.

Exploration of Air: Out of the World North of Nigeria. By A. Buchanan. Pp. xxiv + 258. (London: John Murray, 1921.) 16s. net.

THE journey which Mr. Buchanan describes in this volume was undertaken at the instance of Lord Rothschild. Its object was to link up the chain of zoological geography across the country lying between Algeria and Nigeria. Starting from Kano in Northern Nigeria, the author traversed the French Territoire Militaire du Niger of the Western Sudan and reached the mountainous region of Air, which had not been visited by any European since Dr. Barth passed through it seventy years ago. Mr. Buchanan's style is vivid and his narrative racy; he touches but lightly on the hardships he had to endure in this arid section of the African continent. He is at his best when he describes the vicissitudes of tracking down some much coveted specimen. His accounts of the natives with whom he came into contact, although not sufficiently detailed to be of much value to the ethnologist, will give the general reader a very good idea of the character of these peoples. He devotes a chapter to the Touaregs of Air, in which he gives a very fair account of the more salient elements of their culture and of their costume, of which the veil worn by the men is the most characteristic feature. It is to be regretted, however, that he has not given a more detailed description of a people so little known.

The Principles of Radiography. By Dr. J. A. Crowther. Pp. vii + 138. (London: J. and A. Churchill, 1922.) 7s. 6d. net.

DR. CROWTHER'S book is intended primarily for those beginning the study and practice of medical radiology, to whom it should be of considerable service. The author gives in a lucid and practical manner an account of the principles involved in the production of a skiagram and the mode of construction and action of the apparatus used. The subject-matter of the book forms part of a series of lectures given by the author to candidates for the Diploma in Medical Radiology and Electrology at Cambridge University.

The elementary principles receive full treatment, nearly fifty pages being devoted to their consideration. After a description of the properties of X-rays and the peculiarities of X-ray tubes, the production of high-tension currents is treated. The remaining chapters are devoted to the various parts of an X-ray installation, the actual taking of skiagrams, and the localisation of foreign bodies.

The description given to Fig. 25 will no doubt be altered in a future edition and the X-ray tube depicted in Fig. 26 be given terminals of different signs. Though written by a physicist, it is evident that the writer has had some practical experience in the radiography of the human subject, which enhances the value of the book.

The Principles of Mechanical Refrigeration. (A Study Course for Operating Engineers.) By Prof. H. J. MacIntire. Pp. viii+252. (New York and London: McGraw-Hill Book Co., Inc., 1922.) 12*s*. 6*d*.

THE engineering courses at our Universities and Technical Schools deal as a rule much more thoroughly with the conversion of heat into work than with the conversion of work into heat, or rather, into the absence of heat. This holds to a considerable extent for American universities and colleges, and it is for engineers so trained that the present volume is intended. Attention is directed chiefly to the details in which refrigerating machinery differs from the machinery with which the average engineer is familiar. It is probably due to the simplicity of the new problems which the ammonia refrigerating plant brings before the mechanical engineer that ammonia owes its popularity. The actual cost of producing a given amount of refrigeration is almost the same by the three or four methods at present in use, and the author of the present work thinks that the carbonic acid has many advantages over the ammonia method. Ethyl chloride used with a rotary compressor is extensively used in the American Marine, and much more information on the use of this material would be welcomed by refrigerating engineers in this country. The book contains tables of the properties of refrigerants compiled from Bureau of Standards reports, which are more up-to-date than any with which we are acquainted in books published in this country.

The Stagery of Shakespeare. By R. Crompton Rhodes. Pp. xii+102. (Birmingham: Cornish Bros., Ltd., 1922.) 4*s*. 6*d*. net.

MR. RHODES's little book is an important contribution to the study of the stage-craft of Shakespeare and his contemporaries. His method has been to compare closely the stage directions of the quarto editions of the plays and those of the First Folio. He finds that in the quartos which are generally recognised as pirated, the stage directions have the character of observations rather than of instructions, as might be expected from the circumstances of their origin. As a result of the comparison, Mr. Rhodes is able to offer a number of suggestions as to the use of the curtains to provide a recess on the stage and the use of the balcony covering the three terms used by Shakespeare, "aloft," "above," and "at a window." His deduction that in those cases in the First Folio, where there are no stage directions or very few—"The Two Gentlemen of Verona," "The Merry Wives of Windsor," "Measure for Measure," "The Winter's Tale," and "King John," —we are dealing with a text assembled from the players' parts, deserves attention in the consideration of a difficult problem, for the solution of which Sir Sydney Lee's theory of transcripts in private hands does not appear entirely convincing.

Twenty-Five Years in East Africa. By Rev. John Roscoe. Pp. xvi+288+xix Plates. (Cambridge: At the University Press, 1921.) 25*s*. net.

IN this volume, Mr. Roscoe has given an account of some of his experiences and observations of the manners and customs of the natives of East Africa during his twenty-five years' service as a missionary in that area. In particular his aim has been to describe the condition of the country and the natives when first he took up his work. From this point of view, his book forms a useful pendant to the more strictly ethnographical works he has already published dealing with the Baganda and other Bantu tribes. The connected narrative adds colour to these analytical studies. When Mr. Roscoe first arrived in the country the Uganda railway, of course, was not in existence, and he gives a vivid picture of the difficulties encountered by the traveller, arising both from the character of the country and the untrustworthiness of the native carrier, the only means of transport. To many of his readers the most interesting section of the book will be that dealing with the events, of which he was an eye-witness, leading to our assumption of the Protectorate over Uganda. In this account, curiously enough, Sir Frederick Lugard is mentioned only incidentally.

Joseph Glanvill and Psychical Research in the Seventeenth Century. By H. Stanley Redgrove and I. M. L. Redgrove. Pp. 94. (London: William Rider and Son, Ltd., 1921.) 2*s*. 6*d*. net.

JOSEPH GLANVILL is no doubt best known to the modern reader as the source of inspiration of Matthew Arnold's well-known poem, and secondly as author of a treatise on witchcraft which W. E. H. Lecky described as "probably the ablest book ever published in defence of the superstition." It is not so generally known that Glanvill was an ardent advocate of the experimental method and a sturdy opponent of dogmatism. He was not only a Fellow of the Royal Society, being elected in 1664, and a friend and admirer of Robert Boyle, but in addition to making three communications to the society which appeared in the Transactions, he was the author of an account of the advances in the various departments of scientific knowledge since the time of the ancients. Incidentally in this work he suggested that the Torricellian vacuum was not an absolute void. In the short account of Glanvill under notice his various activities are noted and his views set forth, for the most part, in his own words. The authors are, however, chiefly interested in his psychic investigations, on account of which he may be considered, legitimately, to be the founder of modern psychical research.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Difference between Series Spectra of Isotopes.

PROF. P. EHRENFEST and Prof. N. Bohr, in their letters to NATURE of June 10, have raised the interesting question of the difference to be expected between the spectra of isotopes. Much confusion, as their letters clearly indicate, exists on the subject, and while not in disagreement with any of their conclusions, I should like to make a few remarks which may tend to elucidate the matter somewhat further.

Prof. Ehrenfest raised the question in relation to the spectra of the isotopes of lithium—the subject of an investigation by Prof. Zeeman—and pointed out that the factor $M/(m+M)$ in the Rydberg constant was only deduced by Bohr and subsequently used by Fowler to obtain the best estimate we have for the ratio m/M, in his Bakerian lecture—for the case of an atom with a *single* electron. He justifiably rejects any conclusions founded on its application to atoms with more than one electron, and Prof. Bohr entirely concurs. Ehrenfest's illustration of an atom in which the mass of the nucleus, on account of symmetry, does not enter into the spectrum at all, is perhaps a sufficient indication of the difficulty of the problem, if such symmetrical atoms can exist, a matter which appears improbable.

The spectra of the lithium isotopes are at present peculiarly interesting since the announcement that Prof. M'Lennan has isolated them and found a difference which is greater than that calculated by the Bohr formula, and in fact three times this value, while 3 is the accepted atomic number of lithium. The quantum theory is unable to explain this large separation, and its exponents must doubt the fact that M'Lennan's new series is the spectrum of an isotope. There are two alternatives—it may be a combination series or a spark series. In an investigation which the present writer made a year ago, on some of the simpler possible orbits in a lithium atom with only two electrons, a specially simple class of orbits was found. Although the work is not yet published, it is possible to state that its result gave, as the principal spark-line of lithium, a value very close to $\lambda 6708$, the red line shown in the ordinary spectrum. This line had already been suspected, by several spectroscopists, to have a spark component.

In these simple orbits of a lithium atom positively charged, the two electrons are behaving very differently. The orbit of one of them is only about $\frac{1}{10}$ the linear dimensions of that of the other, so that the Bohr formula for one electron is nearly applicable. In fact, the orbits are very closely analogous to those now generally accepted for the neutral helium atom, which can take two forms, in both of which the orbit of one electron is very small compared with that of the other; the orbits differ mainly in the fact that in ortho-helium they are practically coplanar, and in parhelium practically perpendicular.

I have found it possible by a choice of the simpler orbits, and by the supposition made by Sommerfeld and others as to the invariability of the energy W for all possible orbits, to show that the inner orbit has a radius only about $\frac{1}{10}$ of that of the outer. Thus the Bohr formula is again nearly true, and the Rydberg constant in the ordinary helium series is not very different from its value in the Pickering series. Such results are suggestive, and appear to indicate that when there are many electrons in an atom, a ratio roughly of order $\frac{1}{10}$ exists between the orbital radii of the two outer consecutive electrons. An immediate consequence is that the Bohr formula would never be very far wrong in its use for a rough determination of the separation to be looked for in the spectra of isotopes. If the correspondence with these results does not, however, extend to heavier atoms, we are precluded from making any prediction without the knowledge of the general position—on the average—of the centre of mass of an atom. In a problem of this nature no general treatment is possible, and no general simple law of separation down the Periodic Table is to be expected.

J. W. NICHOLSON.

A Possible Reconciliation of the Atomic Models of Bohr and of Lewis and Langmuir.

BROADLY speaking, the merits of Bohr's atomic model lie in its very accurate explanation of the reaction of atoms and molecules with radiation, while those of the Lewis-Langmuir model lie in its very satisfactory representation of the mechanism of chemical combination, but the merits of either model are lacking in the other. Both must therefore possess properties which are accurate representations of the truth, and the problem remains to devise a third model which will incorporate those properties in its structure. The following considerations lead to a modification of the Lewis-Langmuir model, which appears to be a satisfactory solution of the problem—so far as I am aware it is new.

Consider first the well-known Lewis-Langmuir model for any atom. It is built up of the central nucleus and its surrounding electrons the mean positions of which are fixed with respect to one another and to the position of the nucleus. Now in order to account for the reaction between the atom and radiant energy it is necessary to assume that these electrons possess acceleration of some kind. The particular kind most agreeable with the results of experiment is the orbital acceleration assumed by Bohr. But since the electrons are fixed (or can be assumed to move but very slightly from their fixed mean positions) in the Lewis-Langmuir model, orbital acceleration is impossible.

Now, apparently, a way out of this difficulty is to assume that the electron shells are fixed and the nucleus rotates on an axis.

By the Theory of Relativity it is immaterial whether—viewing a given atom—we regard the electrons as describing orbits around a fixed nucleus (not fixed in position only) or whether we regard the nucleus as rotating inside the electron shell or shells with each electron fixed relatively to the others. That is, the nucleus possesses acceleration with respect to the electrons, or what is the same thing, the electrons possess acceleration with respect to the nucleus in spite of the fact that they are fixed relatively to outside systems such as other electron shells. Therefore this model when viewed with respect to the electron shells is precisely the same as the Lewis-Langmuir model, and, furthermore, with respect to the whole atom it possesses all the merits of Bohr's model. That is, it appears to be a satisfactory reconciliation of the two atomic models.

Furthermore, the proposed model possesses the further merit that by its aid we can predict the existence of isotopes. Thus if the nucleus of a given atom possesses more than one stable axis of rotation with respect to itself, or to its surrounding shells of elec-

trons, or to both, and these axes are associated different amounts of energy, it is possible for the mass of the atom to be different for the different positions of the nuclear axis, since by the Theory of Relativity energy possesses mass. That is, the model proposed predicts the existence of isotopy. If the direction of the nuclear axis as described above is determined by the structure of the outer shell of electrons, we should expect the existence of different axes in the same atom to be favoured in those atoms the outer shells of which are complete (inert gases), nearly complete (halogens), or just forming (alkali metals). An inspection of Aston's list of isotopic elements shows that it is in the neighbourhood of the inert gases that the phenomenon of isotopy chiefly occurs

The Intensity of X-ray Reflection from Powdered Crystals.

In the May number of the *Philosophical Magazine* which has just reached us, Mr C G Darwin has presented a most valuable discussion of the reflection of X-rays from imperfect crystals He shows that, on account of the difficulty in determining the effective extinction coefficient of the X-rays in such crystals, it is very difficult to calculate with accuracy the intensity of the reflected beam Hence he is unable to make a satisfactory comparison between the theoretical formulæ and the existing experiments on the intensity of X-ray reflection This result is in general agreement with the conclusion reached by one of us (*Physical Review*, July 1917) on the basis of somewhat similar considerations

Mr Darwin concludes that a more satisfactory test might be made on powdered crystals, since in this case the only factor contributing appreciably to the extinction is the ordinary absorption of the X-rays in the powder, which can be measured directly. We had arrived at the same conclusion, and have made quantitative measurements of the intensity of the X-rays scattered by powdered crystals

In our most recent experiments, the $K\alpha$ line from molybdenum ($\lambda + 0{\cdot}708$ Å), after reflection from a crystal of rock-salt, was allowed to fall upon a plate of powdered sodium chloride The first order reflection from the [100] faces of the powdered crystals then entered the ionisation chamber The method was thus similar to that employed by W. H Bragg (Proc. Phys. Soc, Lond, 33, 222, 1921) except that the primary rays were homogeneous. The ratio of the energy reflected into the ionisation chamber due to this first order line to that incident upon the plate was $2{\cdot}94 \times 10^{-4}$, with a probable error of about 10 per cent The theoretical intensity of the line was calculated from a formula identical in significance with Darwin's formula (10·4) (*loc cit.*), except that correction was made for the absorption of the X-rays in the crystal mass We thus obtained the value $2{\cdot}7 \times 10^{-4}$, which is in satisfactory agreement with the experimental measurement Thus, at least to a close degree of approximation, the theory of X-ray reflection based upon the classical electrical theory gives accurate results

This comparison of theory with experiment may be viewed in another manner Any formula for the intensity of X-ray reflection must depend upon the value of a function ψ, the magnitude of which is determined by the distribution of the electrons in the atoms. The theoretical value $2{\cdot}7 \times 10^{-4}$ mentioned above is based upon the value $\psi^2 = 0{\cdot}59$, i.e. upon the assumption that the intensity is 59 per cent. as great as it would be if all the electrons in sodium and chlorine were grouped together at the centres of their respective atoms. This value was estimated by one of us (*loc. cit.*) on the basis of some of W. H. Bragg's measurements of the relative intensity of the different orders of X-ray reflection from rock-salt. The corresponding value of ψ^2 as determined by the measurements of W. L. Bragg, James and Bosanquet is 0·43 (*Phil. Mag.*, July 1921) To obtain our experimental value $2{\cdot}9 \times 10^{-4}$ for the intensity of reflection from powdered crystals, the value of ψ^2 must, however, be 0·64 The difference between the latter two values of ψ^2 supports Darwin's suggestion that the method employed by Bragg, James, and Bosanquet for studying the intensity of X-ray reflection is not wholly trustworthy.

We hope in the near future to be able to report experimental results of a considerably higher degree of accuracy than those described above.

Discoveries in Tropical Medicine.

I am much astonished to learn, for the first time, from Dr. L. W. Sambon's letter in Nature of May 27, that during the whole period of my work in India (from April 1895 to February 1899) he "was almost daily at Manson's house" and was allowed to read my private letters to Manson and to "discuss every detail" Are we to understand by this that his almost daily visits to Manson's house continued for all this period, and that during it he read all my letters to Manson, numbering 110, and averaging a thousand words each in length; or merely that he read a few of the letters which Manson showed to him from time to time? Dr. Sambon would appear to claim the former interpretation of his words, because he proceeds to suggest that he is intimately acquainted, in consequence of his knowledge of these letters of mine, with all details concerning the relations between my work and the theories of Manson If so, I can only say that I am amazed and hurt. Many of my letters to Manson were of a very private nature, and it is difficult for me to believe that he would have handed over the whole of this correspondence without reserve to a gentleman who was at the time a stranger to me and was in no way concerned with my affairs.

Moreover, when Manson sent some of my letters to Lord Lister he was, of course, careful to inform me of the fact, but he never mentioned the name of Dr Sambon, so far as I remember, in all the fifty-six letters which he wrote me in reply to mine, as surely he would have done had he decided to submit my letters to a third person without my previous consent. Nor did Sir Patrick Manson ever mention this matter to me during the many years which have elapsed since the correspondence referred to ceased. On the other hand, if Dr. Sambon did not see all my letters to Manson, including the private letters, he cannot possibly have that close knowledge of my work which he seems to believe he possesses.

The remainder of Dr Sambon's communication in Nature referred to makes me still more doubtful regarding the interpretation which is to be placed upon his words, for it seems to me that he does not understand the said relations between my work and the theories of Sir Patrick Manson. May I also take the opportunity to state that I for one can scarcely accept as sound any of the conclusions which he has set forth in your columns in the letter referred to.

Ronald Ross.

The Oldest known Rocks of the Earth's Crust.

MAY I welcome Prof. A. P. Coleman's letter on "Geology and the Nebular Theory" in NATURE for June 17, p. 775? It must be admitted that the achievement of A. C. Lawson at Rainy Lake in 1887, the elucidation by Sederholm of the floor of Finland, and the illuminating work of Canadian geologists, including Coleman, Adams, and Barlow, on the Grenville Series, have been slow in penetrating academic circles in the British Isles. The doorways were almost closed against them, and against the views of French geologists also, by the dead-weight of theories of dynamic metamorphism. Yet our confidence in a fundamental "Lewisian" gneiss was well shaken thirty years ago by Sir A. Geikie's announcement that this rock penetrated a sedimentary series (see A. Geikie, "Text-book of Geology," 4th ed., vol. 2, p. 890); and a more detailed acquaintance with the ground would have led the same observer to withdraw his statement (*ibid.*, p. 895) as to a "violent unconformability" between gneisses and Dalradian sediments in north-west Ireland. Some of us have lost no opportunity of comparing the conditions in our homeland with those of broader Archæan areas. But even in our narrow lands, as I have ventured to urge from 1900 onwards, the teaching of the rocks themselves is unmistakable. The oldest known rocks are sediments, and the streaky structure of our ancient gneisses again and again records the stratification of ordinary sediments invaded by a granite magma.

I have recently put this view before those who may not be geologists in a volume of "unconventional essays," containing a chapter on "The search for the foundation-stones," where Prof. Coleman will find that his expositions have not been thrown away upon those whom he has so kindly guided in the field.

GRENVILLE A. J. COLE.

An Exception to the Principle of Selection in Spectra.

IN a recent communication (*Phil. Mag.*, April 1922) Messrs. Foote, Mohler, and Meggers have described the excitation of a certain type of combination lines in a new form of discharge tube in which the *applied* electrostatic field can exert no influence upon the radiation. Thereby they made it somewhat doubtful whether these and other exceptions to the principle of selection can be attributed to the incipient Stark effect of the applied field, as suggested by Sommerfeld and others. In reply to this, Prof. N. Bohr has pointed out (*Phil. Mag.*, June, 1922) that, "owing to the screening from external forces, the experimental arrangement described would be especially favourable for the accumulation of ions in the region of the discharge tube," and that "the field due to the neighbouring ions and free electrons, to which the emitting atoms have been subject, may be of the order of magnitude claimed by the quantum theory for the appearance of the new lines." Consequently Prof. Bohr thinks that the results of Foote, Mohler, and Meggers do not furnish a sufficient basis for the conclusion they have drawn.

Recently, however, in the course of an investigation on the absorption spectrum of potassium, the results of which will be published shortly, the combination lines $1s-2d$ ($\lambda 4642$) and $1s-3d$ ($\lambda 4649$) have been obtained as absorption lines. The existence of free electrons and the consequent electrostatic field of atomic origin in the absorption tube is highly improbable. The present experiment therefore seems to support the conclusion drawn by Messrs. Foote, Mohler, and Meggers.

The Melbourne University Bill.

IN the issue of NATURE for March 16, which has just reached Australia, there is a leading article on the Melbourne University Bill. That Bill was drafted more than eighteen months ago, and though we have a Government in sympathy with the highest ideals of our University, it is still a Bill and has not yet become an Act of Parliament. In the article in question reference is made to a statement drawn up by the University Association of Teachers, in which the council of the university is criticised for failure adequately to protect the interests of the university and its staff.

It would be unseemly, and probably uninteresting to a large section of your readers, to enter into the merits of a "family quarrel" which is the result of misunderstanding and is, we hope, of a temporary character. A letter was sent by the council to the Minister for Public Instruction immediately after the council was informed that the statement to which you refer had been forwarded to members of the Cabinet by the University Association of Teachers. Let me point out a fact of which you may not be aware, namely, that while the association contains the majority of the teaching staff it does not represent the whole body of professors and lecturers. The statement of the association is crude and contains serious inaccuracies. I shall deal only with the two criticisms of the council which you single out.

(1) It "failed to protect the interests of the university by not raising fees." That is not a mere financial question—it involves a question of general policy. In view of the fact that an important section of our community believes that the university should charge no fees (the University of Western Australia is free), would it not be childish to raise the fees before Parliament has settled what our grant is to be, and till we know definitely whether that grant will enable us to pay adequate salaries without raising them?

(2) The council failed "by asking for an inadequate increase of the State Grant." I wish we could have an increase of the grant for the asking. I think the attitude of the council is clearly indicated by an extract from the letter to the Minister for Public Instruction already referred to. You will there find the following:

"The council is placed in a false position by being obliged to correct these statements, for it does not wish it to be inferred that it thinks the proposed increase of the University Grant sufficient for what are now in 1921 its legitimate needs."

The management of the university council may not satisfy the impatience of some, but no one interested in university education need fear that it will fail for lack of whole-hearted zeal.

J. H. MACFARLAND,
Chancellor.

The University of Melbourne, May 5.

[The two criticisms to which Sir J. H. MacFarland, Chancellor of the University of Melbourne, refers, were made by the University Association of Teachers, and we expressed no opinion upon them, but we remarked, "It is obvious that if a university staff is thoroughly discontented its efficiency is bound to suffer." The suggestions made at the end of our

article were offered in the hope that they would assist in settling the difficulties that had arisen between members of the staff and the council.—EDITOR, NATURE.]

Ball Lightning.

AMONGST the notes in NATURE of August 4, 1921 (vol 107, p 722), is a reference to the occurrence of ball lightning during a thunderstorm at St John's Wood on June 26 The phenomenon, it is added, is of great rarity The following therefore, apparently another instance of this phenomenon, may be worthy of record in NATURE It was communicated at the time to the Meteorological Office in Sydney On the evening of January 13, 1920, a very severe thunderstorm with heavy rain occurred in Sydney. About 9 P M I went out on to the verandah of my house at Neutral Bay, which overlooked the harbour, to watch the progress of the storm This was soon after its beginning, and the lightning was very vivid and frequent and the rain heavy Looking towards Mosman Bay, I saw descending, rather slowly in an oscillating way, a large ball of light, seemingly about the size of a Chinese lantern. This took about two seconds to descend and be lost to sight in the hollow towards which Mosman Bay itself lay. The light seemed to have a violet tinge No rays emanated from it No noise was heard

Ouramoeba

I SHALL be glad to know whether any readers of NATURE interested in the Rhizopoda have met with specimens of Leidy's *Ouramoeba botulicauda*? While examining some squeezings of Sphagnum from Woodbury Common, near Exeter, a few days ago, I found an active individual and had it under observation for some time Fig 14 on Pl IX of Leidy's "Fresh-water Rhizopods of North America" might have been drawn from my specimen

It is now generally conceded that the characteristic jointed appendages are filaments of a parasitic alga, and Archer described amoebae in this condition, from Ireland, in 1866, but I am anxious to ascertain whether similar observations have since been made in other parts of Great Britain? F R ROWLEY

Royal Albert Memorial Museum, Exeter, June 8

DR W. L. POTEAT of Wake Forest College, N C (U.S.A), published in NATURE of May 24, 1894 (vol 50, p 79), a letter recording his finding of Ouramoeba in Wake Forest, N C, and asking for citations of other records To this inquiry Mr Rowley's note furnishes a late reply, for there has been no other (in NATURE) in the interval There is now, however, a good deal of literature on the subject Ouramoeba, as Dr Poteat was the first to demonstrate beyond doubt, is simply Amoeba spp (*A. nobilis* Penard, *proteus* Rosel, *binucleata* Gruber, *villosa* Wallich) infested with fungal spores and filaments. In 1898, Mr. Martin F Woodward of the Royal College of Science sent Dr Poteat drawings of an infested Amoeba presumably found in the neighbourhood of London (*Science*, N S viii., 1898, p. 781). There does not appear to be any other record for England The latest memoir by E. W. Gudger, "On Leidy's Ouramoeba," is in Journ. Elisha Mitchell Sci. Soc., xxxii., 1916, p 24.

The Elliptic Logarithmic Spiral.

WITH reference to Dr. Rowell's letter in NATURE of June 3, p 716, it may be pointed out that his curve, so far from being new, is briefly discussed in Besant's "Dynamics" (Besant and Ramsey, "Treatise on Dynamics," pp 101-2) The equations of the curve may be written

$$\left.\begin{aligned} x &= \alpha\xi + \beta\eta \\ y &= \gamma\xi + \delta\eta \end{aligned}\right\}$$

where (ξ, η) lies on a certain logarithmic spiral The curve is thus obtainable from this spiral by a homogeneous strain, whence, amongst others, it will have the property that its various branches cut a radius vector at the same angle: this angle differing for different radii vectores C E WRIGHT

Seasonal Incidence of the Births of Eminent People.

IN order to find, if possible, the causes which underlie the production of increased numbers of eminent intellects at certain periods (as, for example, the year 1809 and a year or two before and after it), I collected statistics of the dates of birth of more than two hundred eminent persons The list consists chiefly of creative intellects,—poets, literati, musicians, painters, architects, men of science, explorers, and inventors, with a few statesmen and military men. Analysis of the dates shows that the greater number of these persons were born in the colder months of the year, but the distribution of the numbers is somewhat erratic February is distinctly the richest month, having produced a galaxy of eminent persons, December comes next, August and June are the richest among the warm months

Sixty pre-eminent names, chosen for no reason but their pre-eminence, were found to be distributed as follows —In warmer months: April, 4, May, 6, June, 7, July, 2, August, 5, September, 3; total, 27 In colder months October, 4, November, 1, December, 9, January, 5; February, 9, March, 5, total, 33.

The difference is more evident when the months are taken in groups of three, as follows December to February, 23; March to May, 15, June to August, 14; September to November, 8

In order to find whether this distribution corresponds with the ordinary distribution of births through the twelve months, I compared the numbers with the average of twelve years taken at a venture from the Registrar General's Quarterly Returns, namely, the period 1844 55 The figures are too numerous for quotation, but it may suffice to say that I could find no correspondence between the ordinary distribution of births and the distribution of births of eminent persons In the Registrar General's Returns the order of average frequency for the quarter-years was as follows: April to June, July to September, January to March, October to December

Climate can scarcely explain the distribution, (See letter from Dr Robert W. Lawson, NATURE, June 3, p. 716) Cold weather is not unhealthy for children, and in fact the diseases of the hot months are among the most fatal for them I suggest that the reproductive organs, especially the germ cells, are more vigorous at certain seasons, producing offspring of higher quality. The many eminent persons born in the winter months, December to February, were conceived in the spring, the time of increased vigour of most living things; whereas the few born in the autumn months, September to November, were conceived in the winter. Cambridge, June 17, 1922.

The Paris and Liége Meetings of the Institution of Mechanical Engineers.

THE summer meeting of the Institution of Mechanical Engineers was held on June 12-21 in Paris and Liége. In Paris the meetings were held in the Hall of the Société des Ingénieurs Civils de France. At the opening session M. Max Laubeuf, the president of the French society, and the engineer who more than any other has been responsible for the development of the submarine, received the president, Dr. H. S. Hele-Shaw, and members of the Institution of Mechanical Engineers, and addressed a few words of welcome. M. Laubeuf had expected to be away from France at the time of the meeting, and the formal address of welcome was therefore delivered by the vice-president, Prof. Leon Guillet.

The first paper was by Prof. Edouard Sauvage, on feed-water heaters for locomotives, in which various types were described, and the economies that might be expected from their use discussed. The second paper was an important contribution from Sir Vincent Raven on the electric locomotive. Broadly speaking, there are three types of locomotives required for the successful working of railways, namely: shunting, freight or goods, and passenger locomotives. For passenger traffic it is not so easy to standardise locomotives as for the other purposes, and considerable difficulties are met with in designing high-speed locomotives of great power. Particulars of a number of electric locomotives designed by the author and others were given, but the most interesting was an experimental locomotive that had been designed by Sir Vincent Raven, and built by the North Eastern Railway to haul a train of 450 tons, of sufficient power to start from rest on a rising gradient of 1 in 78, to reach a speed of 65 miles an hour on the level, and to run with safety at 90 miles per hour. The paper is an important one, and will arouse considerable interest. The chief engineer of the Paris-Lyon Railway, who is considering the same problems, spoke enthusiastically of Sir Vincent Raven's work. The agreement of these two engineers to compare their experiences is a real example of that *entente cordiale* which such gatherings must of necessity do so much to encourage. Lord Montagu of Beaulieu, in a paper on mechanical vehicles and road surfaces, directed attention to the economic importance of good road surfaces.

The first paper read on the second morning at Paris was a very important contribution by Prof. A. Rateau on the subject of rapid high-altitude flying. The author pointed out that the aeroplane is the only vehicle in which the resistance to travel is independent of the speed, and is directly proportional to the weight for the same angle of incidence. For high speeds, the aeroplane must select a height at which the density of the air is most suitable, and, providing the power of the engine can be maintained, high speeds can most easily be obtained at high altitudes. The rarefaction of the atmosphere at high altitudes makes it impossible without some special device to maintain the power of the engine, and, furthermore, pilots and passengers cannot exist in the rarefied atmosphere without special provision of oxygen, or being in an air-tight chamber to which air can be supplied under pressure. Prof. Rateau has attempted to overcome the former difficulty by using exhaust gases from the engine to drive a turbine compressor which will supply air to the engine at ground-level pressure, and also, it is hoped, to the pilot and passengers in the air-tight chamber. Although in this country, in France, and in Germany a good deal of attention has been paid to supercharging of the engine in order to maintain power, Prof. Rateau's paper is the most serious contribution that has been published on the subject. In certain trials the turbo-compressor was made to revolve at speeds up to 53,000 revolutions per minute, giving a peripheral speed of 670 m. per second at the tips of the compressor. In the gas turbine, speeds were attained which gave stresses due to centrifugal force equal to 123,000 times the weight of the material. Moreover, the turbine is worked at a temperature of from 650° to 750° C., and thus very unusual demands are made upon the material.

Prof. Rateau's paper was followed by one on air-compressors by Mr. W. Reavell, of Ipswich, and this again by a paper on the supersaturated condition as shown by nozzle flow, by Prof. A. L. Mellanby and Mr. W. Kerr. It has been suggested that an explanation of the discharge through a nozzle being greater than that required by theory can be found by the assumption that the rate of change of pressure in a nozzle is so great that supersaturation of the steam takes place. The assumption is apparently justified by Wilson's experiments, but it is difficult to see how the conditions for a Wilson effect could be obtained in a nozzle. Prof. Mellanby's experiments confirm those of other workers in showing that the flow is greater than could possibly obtain if the steam did not become partially supersaturated. In the apparatus used search tubes were placed in the nozzles to determine the drop of pressure along the nozzle, and from an examination of these and the discharge through the nozzles, the condition of the steam was obtained. The experiments show that the flow at and near the dry state is excessive when compared with the theoretical, but that the form of the flow curve over a small range of superheat beyond the initially dry condition is not in agreement with the assumption of complete supersaturation.

The last paper read at Paris was one by Prof. F. C. Lea on the effect of temperature on some of the properties of metals, in which it was shown that the effect of temperature on the elastic properties of metals may be more important than upon the ultimate breaking strengths. The significance of this paper was well illustrated by the difficulties referred to by Prof. Rateau in his paper on turbo-compressors.

An interesting and important public lecture was given by Prof. E. G. Coker, on Recent Photo-Elastic Researches on Engineering Problems. The lecture was illustrated by a number of large scale experiments, showing the stress produced in wheel teeth transmitting power and in material being cut in the lathe in planing machines and in milling machines. The experiments aroused much interest and enthusiasm, and the lecturer is to be very sincerely congratulated upon the success of a lecture necessitating the conveyance to France of so much delicate apparatus.

A distinguished gathering was held at the Hôtel Continental on Thursday, June 15. Prof. Leon

Guillet, responding to the toast of the French engineering society, replied eloquently, recounting the work that had been done concurrently by French engineers and men of science in the many developments that had taken place during the last century.

Following the very successful meetings in Paris, members of the Institution journeyed to Liége to participate with l'Association des Ingénieurs sortis de l'École de Liége in the celebration of the seventy-fifth anniversary of the foundation of the Liége Society, which coincided also with the seventy-fifth anniversary of the foundation of the Institution of Mechanical Engineers. In connexion with this anniversary an international scientific congress and exhibition had been arranged by the Liége Society, and this was opened by the King of the Belgians on June 18. The members of the Institution of Mechanical Engineers received invitations to the opening ceremony. The King in his opening address referred in particular to the importance of the work of men of science and of engineers in developing the resources of the world. On the days following the opening of the exhibition a number of papers were read at various sections of the Congress, and visits were arranged to works in the neighbourhood of Liége. Representatives of the French engineering society journeyed to Liége with the members of the Institution of Mechanical Engineers, and the association of the three societies proved of the greatest interest. It is believed and hoped that the celebrations will do much to bring about that rapprochement between the three peoples which is so essential for the future welfare of Europe and the world.

Absolute Measurements of Sound.[1]

By Dr. ARTHUR GORDON WEBSTER, Professor of Physics, Clark University, Worcester, Mass., U.S.A.

IT is now more than thirty years since it occurred to me to devise an instrument that should be capable of measuring the intensity or loudness of any sound at any point in space, should be self-contained and portable, and should give its indications in absolute measure. By this is meant that the units should be such as do not depend on time, place, or the instrument, so that, though the instrument be destroyed and the observer dead, if his writings were preserved another instrument could be constructed from the specifications and the same sound reproduced a hundred or a thousand years later. The difficulty comes from the fact that the forces and amounts of energy involved in connexion even with very loud sounds are extremely small, as may be gathered from the statement that it would take approximately ten million cornets playing *fortissimo* to emit 1 horse-power of sound.

Before we can measure anything we must have a constant standard. In sound we must construct a standard which emits a sound of the simplest possible character, which we call a pure tone; it will be like that emitted under proper conditions by a tuning-fork, which is described by saying that the graph representing the change of pressure with the time shall be that simple curve known as the sinusoid or curve of sines. From this connexion we say that the pressure is a harmonic function of the time. Unfortunately, the pressure change is so small that at no point in a room, even when a person is speaking in a loud tone, does the pressure vary from the atmospheric pressure by more than a few millionths of an atmosphere. Thus we require a manometer millions of times as sensitive as an ordinary barometer, and, in addition, since the rhythmic changes occur, not once in an hour or day, but hundreds of times per second, if we wish the gauge to follow the rapid changes accurately, we have many mechanical difficulties.

The problem of a standard of emission has been solved by a number of persons, including Prof. Ernst Mach and Prof. Ludwig Boltzmann, and Dr. A. Zernov, of Petrograd, a pupil of the celebrated Peter Lebedeff. The problem of an absolute instrument for the reception and measurement of a pure tone has been also successfully dealt with by a number of investigators, among whom may be mentioned Prof. Max Wien, of wireless fame, the late Lord Rayleigh, and Lebedeff. But there remains a third step in the process, which is as important as the first and the second. Given the invention of the proper standard source of sound, which I have named the "phone," because it is *vox et praeterea nihil*, and of a proper measuring instrument, which should evidently be called a phonometer, there still remains the question of the distribution of the sound in space between the phone and the phonometer. Any measurements made in an enclosed space will be influenced by reflections from the walls, and, even if we had a room of perfectly simple geometrical form, say cubical, and were able to make the instruments of emission and reception work automatically without the disturbing presence of an observer, it would still be impossible to specify the reflecting power of the walls without a great amount of experimentation and complicated theory. Nevertheless, this is exactly what was done by the late Prof. Wallace C. Sabine, of Harvard University, who employed the human ear as the receiving instrument. Those who have made experiments upon the sensitiveness of the human ear for a standard sound will immediately doubt the possibility of making precise measurements by the same ear at different times, and particularly of comparing measurements made by one ear with those made by another. Nevertheless, Sabine attained wonderful success and was able to impart his method to pupils who carried on his work successfully, so that he was able to create the science of architectural acoustics and to introduce a new profession. Still, the skill that required three or four months to attain by Sabine's method may be replaced by a few minutes' work with the phonometer.

In order to avoid the influence of disturbing objects, the observer should take the phonometer to an infinite distance, which is manifestly impossible. The method employed was to get rid of all objects except a reflecting plane covered with a surface the coefficient of reflection of which could be measured. For this purpose the teeing ground of a suitable golf course was used. With the present instrument it can be determined in a few minutes, if there is no wind.

[1] From a Friday evening discourse delivered at the Royal Institution on June 10, 1921.

In 1890 I proposed to use a diaphragm made of paper, which should be placed, shielded on one side, at the point where the sound was to be measured. In order that the effect of the sound should not be distorted, the membrane, instead of having to do any work, as in the case of the diaphragm of the phonograph in digging up the wax, or in that of the microphone in compressing the carbon, was to be perfectly free, but was to carry a small plane mirror cemented on at its centre. In close juxtaposition and parallel with this was the plane side of a lens which, viewed in the light from a sodium flame, was to give Newton's rings, or interference fringes. Of course, when the sound falls upon the diaphragm the fringes vibrate rapidly and disappear from sight.

By the introduction of a Michelson optical interferometer, two of the difficulties of this instrument were overcome, namely, (1) that of adjusting the lens so that it would not strike the vibrating mirror, since the mirrors in the interferometer could be as far apart as one pleased; and (2), more important still, it permitted the use of fringes in white light, so that it was possible to use gas, incandescent, or arc light with excellent effect. A further improvement was introduced by the use of a thin plate of mica for the diaphragm.

To obtain the sensitiveness necessary to measure sounds of ordinary intensity, the property of resonance is employed twice—*i.e.* a system of two degrees of freedom is used. First, the plate resounds to a sound more strongly as it is tuned more nearly to it; and second, a resonator that can also be tuned is put behind the plate. The sound entering by the hole in the resonator is magnified by the tuning, and acts upon the plate, which is also tuned. A graph can be plotted in which one co-ordinate represents the stiffness of the plate, or rather what may be called the mistuning, which is the stiffness lessened by the product of the mass by the square of the frequency. The other co-ordinate represents the corresponding quantity for the resonator, the stiffness of which depends simply on the volume into which the air is compressed, while the

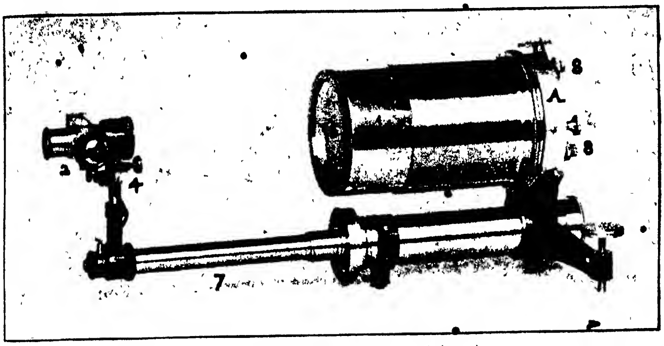

FIG. 1.—Phonometer (Interferometer not shown.)

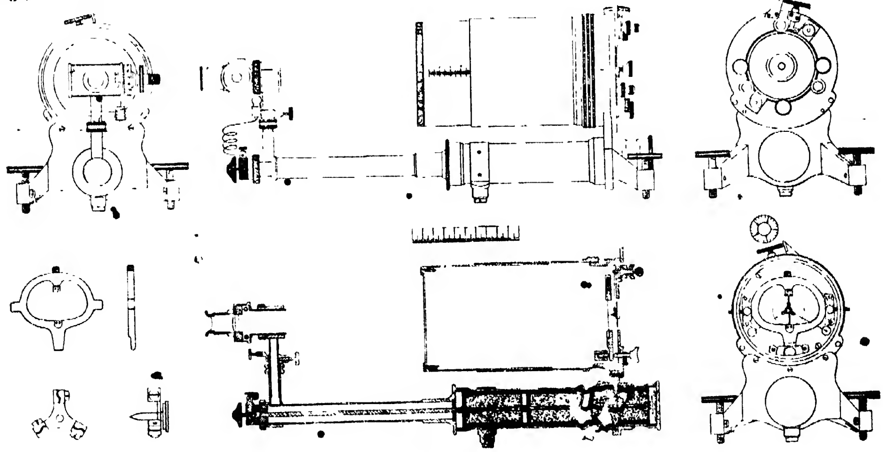

FIG. 2.—Parts of the phonometer.

effective mass depends on the dimensions of the whole, and its damping on the sound radiated from the mouth. It is then found that the tuning should not be such as to make the representative point occur at the middle of the figure, making both mistunings zero, but that both mistunings should be of the same sign and a certain magnitude, depending on the coefficients of damping of the two degrees of freedom of the coupled system. The mathematical theory is precisely that of a wireless receiver. The ultimate sensitiveness depends on the smallness of the damping of the plate.

The apparatus as it was built several years ago was mounted upon a heavy bronze stand, covered at the back by a heavy bronze cover to keep out the sound, while the three shafts turning the screws of the interferometer adjustment protruded through sound-tight fittings. Upon the front of the instrument a properly tuned resonator was attached, and at the side was a

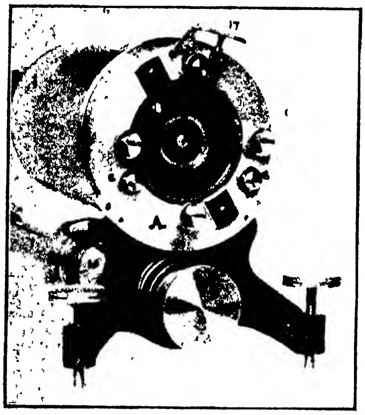

FIG. 3.—Front view of phonometer with annular opening.

small incandescent lamp with a straight, horizontal filament, an image of which was projected by a lens upon the first mirror of the interferometer. Upon this was focussed a telescope, giving in the reticule an image of the horizontal, straight filament, crossed by the vertical interference fringes seen with white light. In order to get these the plate must be in the proper position within a few hundred thousandths of an inch. The objective of the tuning-fork was carried by a tuning-fork which oscillated vertically, tuned to the pitch of the pure tone to be examined, and this, combined with the horizontal motion of the fringes, resulted in a figure of coloured fringes in the form of an ellipse. On slightly mistuning the fork, the ellipse could be made to go through all its phases, and when it was reduced to an inclined straight line its inclination was read off on a tangent scale. The amplitude of the compression of the air in the sound was then directly proportional to the scale-reading.

While the interferometer is still used for calibration, the movement of the diaphragm is recorded for actual measurements by a thin steel torsion strip carrying a concave mirror. A lamp with a vertical, straight filament is viewed through a telescope into which the small mirror focusses the image of the filament on the reticule, and a magnification of from 1200 to 1500 is used, so that the sensitiveness is about the same as with the interferometer.

At first the only method of tuning was the clumsy one of changing the mass of the diaphragm by adding small pieces of wax. This was not capable of continuous variation. Now the diaphragm has been discarded and replaced by a rigid disc supported by three steel wires in tension. The disc is made of mica or aluminium, and is carried by a little steel spider containing three clamps to hold the wire. The tension is regulated by three steel pegs, one of which is controlled by a micrometer screw. The disc is placed in the circular hole through which the sound enters the resonator. This has the advantage of reducing damping very largely, and thus of increasing the sensitiveness enormously. The instrument now competes with the human ear, and can be tuned over two octaves or more.

This sensitiveness can be demonstrated by projecting the coloured interference fringes on a screen and singing faintly in a remote part of the room, when the fringes will disappear. Using the telescope end of the apparatus, the instrument will indicate the sound of a tuning-fork when one can scarcely hear it. It is obvious that the disc may be made the diaphragm of a telephone and thus increase its sensitiveness. In fact, Prof. King has used with great success such a telephone to record wireless messages. He has also invented another sort of tunable diaphragm composed of a stretched steel membrane with compressed air behind it, which enables it to be tuned continuously, but over a smaller range.

I now come to the source of sound—the phone. This has been reduced to a reversed form of the phonometer. The disc is driven by an interrupted or alternating current by means of electromagnets, and tuned like the phonometer. Its excursion is measured by a powerful microscope, and the emission of sound is known in absolute measure. It is now driven by a triode valve tube, in the manner suggested by Prof. W. H. Eccles, of Finsbury Technical College, London, for a tuning-fork. This has been worked out for me by Dr. Eckhardt at the Bureau of Standards in Washington.

The third part of the investigation involves a determination of the coefficient of reflection of the ground. The phone is set at a convenient height, and the phonometer at a convenient distance. Either is then moved along at a constant height and the varying deflections of the phonometer are read while the sound remains the same. Interference sets in between the direct sound and its image reflected in the ground, and the existence of a minimum is obvious to the most naive observer by the ear alone. The reflection of either grass or gravel was found to be about 95 per cent., while, with a most carefully deadened room, the walls of which were covered with thick felt, there was perhaps 20 per cent. reflection. The whole measurement at both ends and the transmission checks up with an accuracy of about 2 per cent.

With this apparatus all sorts of acoustical experiments may be performed. By attaching to the phonometer a long glass tube or antenna, it has been possible to explore all sorts of places such as the

held within a horn, or tube lined with an absorbent substance. The transmission of sound through fabrics, walls, and telephone booths may also be quickly examined. The instrument is used by psychologists and by telephone and acoustic engineers, and is of interest to navigators. An interesting by-product is an instrument for showing the direction of an acoustic signal in the fog. It has been called a phonotrope, on the analogy of heliotrope, which turns to the sun. It consists of two equal horns which bring the sound to the opposite sides of the disc. When the whistle blows, the band of light spreads out, and on turning the instrument it closes to zero when the sound is directly ahead. Thus at several miles the direction is given to within two or three degrees.

Finally, let us consider that mystery of sound, the violin, which has been studied by Prof. Barton of Nottingham, and by Prof. Raman at Calcutta. This may be described by the engineer as a box of curious shape, made of a curious substance, wood, of variable thickness, with two holes of strange figure to let the sound out of the resonating box. The latter is actuated by a curious substance, catgut, made of the intestines of a sheep, and set in vibration by another curious substance, the tail of a horse. Yet from this wonderful box we get the most ravishing sounds, which affect profoundly the emotions of the most civilised. Yet the physicist reduces all musical instruments to combinations of resonators with strings, membranes, bars, plates, and horns. The mathematical theory of strings was given by Euler two hundred years ago, of bars and plates less than a hundred years, of resonators by Helmholtz and Rayleigh, and I have recently added a theory of horns which, while only approximate, works well in practice, and investigations are now being carried out by such methods on vowels and the violin.

Biological Studies in Madeira.

By Dr. MICHAEL GRABHAM.

THE component islands and rocks on the Madeira Archipelago are separate foci of volcanic ejecta in the abysmal oceanic depths, and the level of the Atlantic waters might be lowered 100 fathoms without merging them in a common connexion. Of the 170 forms of Testacea existing in the region, only five species are distributed throughout the Island group, and such evidence is adversely copious and conclusive as to the theory that the Madeiras are a surviving relic of a former continent.

The fossil shells now lifted 1500 ft. above the sea level show an upper Miocene association, but the massive piling up of volcanic matter in countless reiteration of eruption and age-long intermission began long before the fossil shells were living creatures on a Miocene shore.

Examination of a fossil leaf-bed, containing examples of the specific insular flora buried 120 ft. beneath a variety of strata and capped by a thick deposit of white trachyte, shows that the trachyte rock has almost disappeared under the slowly working forces of erosion and disintegration. From this is adduced the enduring quality of the trachyte steps and gateways of Funchal, which have been exposed for two centuries, with little evidence of decay, to the same influences under which the thick leaf-bed cap has vanished. Thus we need set no niggardly limit to the time requirement for the establishment of the specialised forms of life developed and buried ages before the trachyte capped the successive strata in a flowing stream of lava.

The Archipelago came to us 500 years ago, in the dawn of navigation, ready made, already well worn into characteristic scenery, with the local flora stabilised, the discovery being due to the erratic drifting from its course to the West African coast of a crazy vessel of Prince Henry the Navigator. An ancient building is regarded locally as the traditional home of Christopher Columbus, who married the Admiral Perestrello's daughter, and was, no doubt, inspired for his western enterprise by watching the sea currents and the evidence they brought of land and life beyond the horizon.

The agencies of transport and distribution we know; the sea currents are the same; the same winds prevail; the same birds come and go, though it may be difficult to believe that the presence of the Testacea in 170 forms and the Coleoptera in 700 species has been due to fitful and accidental influences. It is difficult, though the rain falls now as formerly, to point to a single rock or ravine as having appreciably lessened or deepened, though the storms of every winter carry thousands of tons of material to the ocean bed.

The completeness with which the natural orders exist in Madeira and the prevalence of specific forms make it less bewildering to believe that these forms of life were brought to us in pots from the Garden of Eden than to trace their descent from primeval forms which no longer survive. The shells can be compared with fossilised ancient types, but the flora has no such satisfactory appeal.

The name "Madeira" is derived from the hard wood known as Materia; Coniferæ are not prominent in the native flora. I have introduced *Pinus Insignis*, *Cupressus Macrocarpa*, and other species, while the seeds of *Persea Indica* have been sent abroad with the view of enlarging the range of the alligator peartree by grafting.

In conformity with other oceanic centres, Madeira has numerous examples of orders with a single genus and of genera with a single species. The striking fruticose echiums illustrate stabilised specific forms, and show how a new bee has effected an important hybridisation by which perennial characters were conferred on a plant of biennial life-limit, the helicoid flowering cymes, normally 2½ inches long, being prolonged into growths 7 or 8 feet high.

The Carniolan bee concerned in this hybridisation at first abstained from fruit eating, but it speedily blended with the local black bee and became a vine-

yard pest. Similarly many attractive flowers have become in Madeira pernicious pests; such are Oxalis, Eupatorium, Scenecio, and *Freezia refracta*.

Madeira could, however, be made a focus for the dissemination of plants of economic value. The gourd, *Sechium Edule*, has remarkable food value, and is very potent in fat utilisation. The plant shows a singular development of the seed-surrounding flesh into the permanent stem growth of the climbing plant. During the stress of war, when German U-boats wantonly destroyed everything and the Island food was restricted to local resources, the potency of the Sechium was realised, and on several occasions the sullen apathy of incipient starvation was awakened into reviving animation under its influence. The gourd was also utilised during the time of construction of the Panama Canal, when the Italian labourers had to be coerced to use a sufficient fat ration in their food in order that they might equal the output of their Canadian fellow-labourers.

Another valuable plant is *Lycopersicum cerasiforme*, which provides an agreeable tomato food with important antiscorbutic qualities. In the Salvage Islets there is also *Monizaa Edulis*, the carrot fern of Madeira, with a species of the apterous Deucalion, otherwise known only on the Madeira rocks, side by side with the Canarian *Samphire astadamya*; this seems to establish a balancing correlation or agreement between the botanic and entomological features of the two island groups.

An interesting illustration of sterility yielding to the introduction of a new pollen is afforded by a species of the Bignoniaceous jacaranda, while the sterility of the banana and the complete loss of fertility in the fruiting *Solanum guatemalense* show, on the other hand, how we are constantly curbing the superabundant seed growth of valued sub-tropical fruits, such as the custard apple and the loquat, which in the fruit-vacant months of Northern Europe should flood British markets both in perfection and profusion.

Many introduced plant pests, such as Peronospera and Oidium, have been brought under control, and even the *Phylloxera vastatrix*, which destroyed the Madeira vineyards before its life-history was made out, has become almost negligible in its depredations; thus the wine of Madeira has returned in adequate and superabundant supply. The Argentine ant may be credited to some extent with restraining the activity of the Phylloxera aphis. In view of the almost certain invasion of the British Islands by this pest, the Board of Agriculture should issue and circulate the American official booklet on the subject, together with a reprint of a paper read by me before the British Association two years ago. No less than 47,000 of these ants have been found engaged in draining a single lemon tree of its vitality; but various agencies of restraint are now employed in the orange and coffee plantations. The common flea and the house-fly do not seem to have abated under the domination of the Iridomyrmex.

The winged ant-queens suffer deälation after mating, and, discarding the cares of motherhood, they issue forth with the workers and found new colonies wherever conditions invite. The intelligent ingenuity of the ant and its tenacity of purpose in the face of obstacles is very remarkable.

As regards oceanic research, organised exploration of the ocean flora and deep-water biology is urgently necessary in the national interest. This investigation is a part of our responsibility in Imperial expansion; a second *Challenger* expedition is long overdue, and could be accomplished at a comparatively small cost.

The fisheries of Madeira provide several novel specimens. The Sherny, *Polyprion Cernier*, freshly brought from the deep sub-tropical water of the Madeira district, is typical of the warmer seas, though occasionally seen farther north. This is the wreck fish of British nomenclature, so known from its association with floating timber logs. The early life of the fish is passed in the sunlit surface waters, but the proper habitat of the full-sized creature, 100 lbs. in weight or more, is in the open sea at the enormous depth of 2000 or 3000 ft.

The fish, when brought to the surface from that profound depth, so distends at the removal from the vast pressure below that it emerges from the water like a cork or bladder, with its stomach forced through the capacious mouth and the eyes protruding in front of their sockets. No explanation is known of the conditions which prompt the fish to descend from the surface warmth into the cold darkness of the abysmal region, where only the larger examples are to be found. That the sea is nowhere azoic is shown by the plump and well-fed condition in which the Sherny comes to the surface. Its dull colouring, which is shared by the Aplurus and *Promethus Atlanticus*, contrasts surprisingly with the brilliant hues of Sebastes, Scorpœna, and Lampris, which also live in the depths, though rarely in close association with their sober-tinted brethren. The Sherny has a large air-bladder firmly attached to the spine, but knowledge of the function of this organ is very imperfect. The regulation of submersibility by a voluntary act of filling, emptying, or compressing is probably only a subordinate physiological function, for the structure of the bladder is suggestive of pulmonary functions, and its firm attachment to the spine and its prolongation upwards to a cerebral connexion with the organ of hearing, seem a sure indication of the use of the organ as a resonator in the interpretation of weak sonorous vibrations. The air-bladder, nevertheless, is totally absent from the Aplurus and many other fishes.

Some of the fishes swimming near the surface are believed to have their air-bladders charged with nitrogen, but extensive observation does not confirm the current idea that in deep water oxygen is the inflating gas. The consumption of oxygen by fish is small, and the standard of respiration in oceanic fish of deep water is low; the heart-beat in the Polyprion will continue many hours after every other sign of life has ceased. Stationary traps are necessary for the investigation of the abysmal forms of life.

The surface plankton is abundant, but the contracted empty stomachs of some of the deep-sea fish is evidence against the idea that much food is dissolved in deep-sea water. The *Aphanopus Carbo* is a voracious monster which abounds in the lesser depths, and ranges freely among the inexhaustible invertebrates of those regions.

During a series of observations on earth-currents in deep-sea cables, strange effects were noted which were

found [illegible] due to a submarine earthquake which broke up many miles of the ocean floor. The occurrence may be compared with a similar commotion which destroyed an important fishery in the sub-tropical waters of the United States.

A full and comprehensive appreciation of sub-tropical ichthyology is necessary to indicate the vast and interesting variety of the fauna and the intrinsic charm of scientific research. It is the duty and interest of the community to discover the potential genius and place him where he can accomplish that for which he is fitted, unfettered by the suppressing restrictions of a false communistic socialism or cramping of individual effort.

Magna opera Domini exquisitae omnes voluntates ejus.

Ten Years of X-ray Crystal Analysis.

By Dr. A. E. H. Tutton, F.R.S.

A SPECIAL number of *Die Naturwissenschaften*, entitled "Zehn Jahre Laue-Diagramm," was issued on April 21, forming Heft 16, 1922, which contains eight articles by authors who have contributed to the subject of X-ray analysis on the continent since its first inception by Dr. M. von Laue, among whom may be mentioned Drs. Friedrich and Knipping, who collaborated with Dr. von Laue in the first discovery, Prof. Debye, and Prof. Niggli. Probably the article of deepest interest to the general reader will prove to be that of Dr. Friedrich, who gives an account of the circumstances in the year 1912 in Munich when the first discovery was made. To the present writer, who was himself in Munich in the summer of that same remarkable year, this memoir is of fascinating interest. It has to be remembered that the scientific coterie at that time forming the professorial staff of the University, Museum, and Institute, included Prof. Röntgen, the generally recognised discoverer of X-rays (although their production had for some time previously been almost a daily occurrence in the private laboratory of the late Sir William Crookes); Prof. von Groth, the founder and editor of the *Zeitschrift fur Krystallographie* and the doyen of crystallographers, whose brilliant lectures on crystal structure and optics attracted students from all over the world; Prof. Sommerfeld, who had carried on the tradition of X-ray physics bequeathed to him by his predecessor Boltzmann and also extended the work of Haga and Wind, and of Walther and Pohl on X-radiograms and the general physics of X-rays; Prof. Ewald, who had studied the behaviour of long electromagnetic waves with space-lattices; and Dr. von Laue, who had specialised largely on the interference phenomena of ordinary optics. It was among this strong combination of crystallographers, X-ray specialists, and diffraction (grating) opticians that the inception of the attack on crystals by X-rays had its birth.

During a conversation between Laue and Ewald, the former raised the question as to how electromagnetic waves would behave which were small compared with the grating constants, and from his optical experience, he suggested that diffraction spectra should be produced. The order of the space-lattice cell dimensions of crystals was already known to be about an Ångström unit (10^{-8} cm.), from the density and molecular weight of the crystal and the mass of a hydrogen atom. The work of Sommerfeld and of Walther and Pohl had led us to expect that the order of dimensions of the wave-length of X-rays would be about one-tenth of this (10^{-9} cm.). Consequently Laue suggested that the conditions should be particularly favourable for the origination of interference phenomena on the passage of X-rays through crystals.

The discussion was continued in the common room, and taken up by the whole, deeply interested coterie, and Friedrich, who was at the time acting as Sommerfeld's assistant, declared himself, with youthful enthusiasm, ready to test the idea practically. He secured the assistance of Knipping, who had more spare time at his disposal, and together they set up the now famous arrangement of X-ray bulb, leaden screens with slits for ensuring the exit of a definite beam of X-rays, simple goniometer carrying the crystal, and photographic plates to receive the expected radiations. At the first attempt the sensitive plates were only arranged parallel to the primary beam of X-rays, as any effect expected appeared likely to be of the character of secondary rays from the crystal, and it was only on repeating the exposure with a photographic plate arranged behind the crystal, perpendicular to the direct beam, that the first Laue radiogram with a crystal of zinc blende was obtained, after several hours of exposure.

Friedrich describes how excited and delighted he was when, alone in his working room at the Institute late that night, he saw the spots appear on the plate under the influence of the developer, due to the deflected X-rays, now known to be reflected from the planes of atoms within the crystal, the planes of the atomic space-lattice. Next morning he went early to show the negative to Knipping, and together they hastened to Laue and Sommerfeld, who were both naturally equally interested and delighted. Prof. Sommerfeld at once excused his assistant from his ordinary duties, so that he might go ahead with further experiments. Both Profs. von Groth and Röntgen, to whom the result of the experiment was at once communicated, supplied materials and gave valuable advice. A much better and more accurate apparatus was erected, including a good goniometer for the exact adjustment of the crystal (which is particularly necessary), and the excellent X-radiograms of zinc blende, quartz, rock-salt, and other crystallised substances, now so well known were obtained as the immediate results.

Dr. Knipping directs special attention in his article to the remarkable work of Siegbahn, who worked with an evacuated apparatus, so as to exclude air absorption of the X-rays, and measured the wave-lengths of the "softer" long wave-length portion of the radiation, eventually discovering and measuring rays as long as ten Ångström units. Compton, it will be remembered, at the other extreme, has measured X-rays (γ-rays

from radium) on the short wave-length side as short as 0·02 Ångström units. Hence, the X-ray spectrum now known comprises waves of all this great range of wave-lengths. It will also be remembered that other researches, such as those of Lyman and Kurth, Mohler and Foote, and Richardson and Bazzoni, have introduced us to rays, termed the K, L, M, and N series, derived by radiations from carbon, oxygen, iron, copper, potassium, sodium, magnesium, and molybdenum, which have wave-lengths ranging to 375 Ångström units, thus bridging over the gap between the shortest ultra-violet rays and X-rays.

Prof. Niggli's contribution offers a survey of the substances the crystal structure of which has now been ascertained by the various X-ray methods of Laue, the Braggs, Debye and Scherrer, and Hull, including a table of the absolute dimensions of the space-lattice cells resulting from the Bragg spectrometric measurements. His concluding remarks are well worth quoting (so far as is possible in translation from the German), especially when it is remembered that Prof. Niggli has now taken over from Prof. von Groth the editorship of the *Zeitschrift für Krystallographie*. "By Laue's discovery crystallography not only obtains a new method of investigation, but experiences a new 'liveliness' in almost every one of its branches. Most especially are we mineralogists glad that our colleagues of the sister sciences now bring to the crystal an entirely new attitude of mind and interest than formerly; for only by the combined and simultaneous labours of all can further research move along right lines."

With these words of Prof. Niggli we must all agree, and it would appear that the sentiment is now so universally accepted and recognised that the future is bright with hope for a progress during the next decade as glorious as that which is now recorded at the termination of ten years of X-ray crystal analysis.

Obituary.

Prof. J. C. Kapteyn, For. Mem., R.S.

JACOBUS CORNELIUS KAPTEYN was born at Barneveld, Holland, on January 19, 1851. He studied at Utrecht from 1869 to 1875, and was then appointed an observer at Leiden Observatory, where he remained for two years. In 1878 he was appointed professor of astronomy and theoretical mechanics at the University of Groningen. He was in the unusual position of an astronomical professor without an observatory, and he immediately applied to the Dutch Government for the means to equip a students' observatory; he mentioned in particular a 6-inch heliometer as desirable. The application, however, was unsuccessful, and for a few years his lectures monopolised his attention. Then, finding that he had time to spare and no instruments, he began to look about for some useful astronomical work of a computational kind that he could carry out. Circumstances soon brought a task well fitted to his tastes.

Photography had been revolutionised by the introduction of the gelatine dry plate about 1880, and its astronomical possibilities were soon exemplified by the successful photographs obtained of the comets of 1881 and 1882. In the latter case Sir David Gill assisted the local photographers by letting them strap their camera to an equatorial, with very successful results; he was impressed by the number of faint stars that were visible on the plates, and the idea of a southern photographic *Durchmusterung* quickly matured in his mind. He found a willing collaborator in Kapteyn, who volunteered to conduct the measurements and reductions at Groningen. Funds were collected from various sources; the Government Grant Committee of the Royal Society voted 300*l.* in each of the years 1885 and 1886; this was, however, stopped in 1887, it is believed from the notion that the Astrographic Catalogue, which was then inaugurated, would obviate the need for the *Durchmusterung*. If that was the idea, subsequent events have proved it to be incorrect. The Astrographic Catalogue is still far from completion, while the *Durchmusterung* has been available as a standard work for a quarter of a century. It might have been made more perfect but for shortage of funds: the plates admitted measurement to seconds of arc, but in practice this was limited to tenths of minutes. Moreover, it was only carried to declination 18° S., instead of to the equator. With a view of shortening the reductions, Kapteyn devised an ingenious measuring instrument, which was practically a small equatorial placed in the position, relatively to the plate, occupied by the centre of the camera lens, the principle being that, since the rays through this point suffered no bending, the star-images, viewed from here, have the same configuration as the stars themselves. Hence right ascension and declination could be read from the circles.

The whole work occupied thirteen years, nearly double the original estimate, but the time was spent ungrudgingly by Kapteyn, and the close examination and discussion of the results brought to light many interesting facts, such as the change of colour-index with galactic latitude, the galactic stars being bluer than the non-galactic ones. It was also found by careful counts that there was no sensible difference in the number of stars recorded at the centres of the plates and near their edges. Several cases of light variation and of rapid proper motion were also found. The question of photographic stellar magnitudes was still in its infancy, but a simple formula was found, mag. = B/(C + diam.), B and C being constants for the plate; as these are printed, it is possible to recover the diameter of each star.

Kapteyn was elected an associate of the Royal Astronomical Society in 1892, and received its Gold Medal in 1902 in appreciation of his work on the *Durchmusterung*. This was, however, only one of the numerous researches that he undertook to investigate the structure of the sidereal universe. He saw the need for increased knowledge of stellar parallaxes. In 1886 he investigated the parallaxes of forty-five stars by the method of meridian transits (since found to be less accurate than the photographic method), and endeavoured to secure that the astrographic plates should each have three exposures at dates of maximum parallactic displacement. This was not

carried out; but Prof. Donner tested the method at Helsingfors, sending the plates to Kapteyn for measurement; he deduced parallaxes for 246 stars, but realised that direct parallax measures were insufficient to gauge more than a small fraction of the universe. He then set to work to deduce distances from the proper motions, incidentally giving a new method of deducing the solar apex by making the sum of the resolved proper motions in the direction of the antapex a maximum, that in the perpendicular direction zero. From this work he deduced formulæ connecting parallax with magnitude and proper motion, which, with some modifications, have been found very serviceable. To the end of his life he entertained a certain distrust for spectroscopic parallaxes, though this scarcely seems to be justified.

In the course of his studies on proper motion Kapteyn made the notable discovery of the two star-drifts, which has played a great part in all subsequent work on stellar motions. It has been interpreted in various ways—as the separate motions of two interpenetrating star-clouds—as radial motions, respectively inward and outward, of stars oscillating through the centre—as rotational movements in opposite directions about the centre. Kapteyn himself favoured the latter view. He saw the necessity of obtaining more statistics about the faint stars, and planned the "Selected Areas" uniformly distributed over the sky; in these restricted regions all available information should be obtained about all the stars down to the faintest visible; from the results statistics for the whole sky could be formed. One of his last wishes was that astronomers should continue to investigate these regions after his death, and his wish will doubtless be realised.

Of late years Kapteyn spent a good deal of time at the great American observatories, and took the keenest interest in the physical investigations there in progress. His last paper on the configuration and motion of the stellar system was published in the *Astrophysical Journal* a few days before his death.

A. C. D. Crommelin.

John Ward.

The National Museum of Wales and the cause of archæology in the Principality have sustained a serious loss by the death, on June 18, of Mr. John Ward. Born in 1856 at Derby, he started in life as a pharmacist, but all his leisure time was devoted to the examination of old buildings and other objects of antiquarian interest. It was this work which in 1893 led to his appointment as curator of the Cardiff Municipal Museum in succession to the late Mr. John Storrie. Here he carried on the same lines of research, which resulted in the publication of several papers in the Transactions of the Cardiff Naturalists' Society and the *Archæologia Cambrensis*, of which probably those on the Roman fort at Gellygaer and the St. Nicholas chambered tumulus were the most important. In addition he wrote for Methuen's series of "Antiquaries' Books" two volumes on "The Roman Era in Britain," and "Romano-British Buildings and Earthworks."

He naturally took a deep interest in the establishment of the National Museum of Wales, and when the Cardiff Museum was absorbed in that Institution he was appointed to the dual post of Keeper of its Archæological Department and Curator of the Cardiff Collections; these duties he discharged with energy and success until failing health necessitated his retirement two years ago.

A conspicuous service which Mr. Ward rendered to the Museum was the accumulation of a large series of obsolete and obsolescent appliances from farms and rural homesteads. These were arranged by him in a temporary "Exhibition of Welsh Byegones," for which he prepared a valuable and interesting handbook. The book found a ready sale and was soon out of print. It was his intention (now, alas, impossible of accomplishment) to prepare an enlarged edition of it, illustrated by drawings from his facile pencil.

One of his striking characteristics was the exquisite finish of every piece of work which left his hands. A conspicuous example of this is the series of models illustrating geological structures, which gained him a silver medal at the Paris Exhibition in 1900.

Mr. Ward had been for many years a Fellow of the Society of Antiquaries, and in 1918 the University of Wales conferred upon him the honorary degree of Master of Arts. Unfortunately the state of his health prevented him from attending the graduation ceremony. He was a keen and enthusiastic student, a man of enlightened views on Museum policy, a loyal colleague, and a warm friend.

W. E. H.

Sir George R. Parkin, K.C.M.G.

Born in New Brunswick in 1846, George Robert Parkin was one of many notable men whom the Maritime Provinces have given to the Empire; but few have had so clear a vision of what Empire means, or have devoted their lives with such ardour to its service. Life in Lower Canada in his early days was strenuous. Farm work, study when body and brain were tired, a meagre living earned by teaching in the common schools, a B.A. degree secured by the practice of severe economy, the Douglas gold medal for proficiency in science. In after days Parkin attributed his intellectual awakening to the influence of a teacher who had been a pupil of Agassiz, although his own bent, after he left the University of New Brunswick, was for the humanities. In 1874–75 he was so fortunate as to spend a year as an unattached student at Oxford, where his eloquence gained for him the office of secretary to the Union at a time when Asquith, Milner, and Thomas Raleigh were its leading speakers. But most notable of the friendships consolidated at Oxford, although it originated through correspondence before he left Canada, was that with Edward Thring, the strength of which is evidenced by the request in Thring's will that Parkin would write his biography. In 1875 he returned to Canada as headmaster of the school at Fredericton.

Parkin was a great talker. His ebullient enthusiasm overflowed in speech; and, just as his enthusiasm was the product of fervid conviction, so also was his talk sincere. He had no conscious mission. His advocacy, in consequence, was irresistible. In 1889 the Imperial Federation League induced him to make a tour through Canada and Australasia. That he should be chosen by the Rhodes Trustees, in 1902, as their first organising secretary, was a proof that it was generally recognised

that, for such a position, his qualifications were unique. Before he resigned this office in 1920 he was able to boast that he had visited every State in the Union and spoken in every University of the Empire. Universities will hold his name in remembrance, not the least of the causes for their gratitude being the paper which he read to the Congress of 1912 on "The Establishment of a Central Bureau; its Constitution and Functions." Re-reading this paper with a knowledge of the developments which have taken place since it was written, one is impressed with the practical character, and even the prescience, of the proposals it contains.

WE note with regret an announcement in the *Chemiker Zeitung* of June 15 that Prof. Wilhelm Wislicenus, director of the Chemical Institute of the University of Tübingen, died on May 8, aged sixty-one years. Prof. Wislicenus was one of the foremost chemists in Germany, and his researches on organic chemistry and stereochemistry are well known.

Current Topics and Events.

AT a meeting of the Council of the Royal Society of Arts on June 29, the president, H R H. the Duke of Connaught and Strathearn, presented the Albert Medal of the Society for the present year to Sir Dugald Clerk, "in recognition of his important contributions, both theoretical and practical, to the development of the Internal Combustion Engine"

THE James Scott Prize of the Royal Society of Edinburgh, established in 1918 for a lecture or essay on the fundamental concepts of natural philosophy, was presented on June 5 to Prof. A. N. Whitehead for his lecture entitled "The Relatedness of Nature."

PROF. L. BAIRSTOW has been elected chairman of the Royal Aeronautical Society for the year 1922–23 in succession to Lieut-Col M. O'Gorman, whose period of office terminates on September 30 next.

AT the annual meeting on June 27 of the Research Defence Society, Sir Walter Fletcher, secretary of the Medical Research Council, gave an address on the work that is being done, by medical research, for the advantage of the life of the nation He took two instances. the study of the vitamins in food, and the action of pituitary extract Both are good examples of work already fruitful, but not yet complete. But they are only two examples, taken almost at random, from a great wealth of material. It would need a big book to describe all that has been done of late years, under the Medical Research Council, for our health and welfare, and it is strange that there should be members of the House of Commons opposed to the spending of public money on this work. The opposition, of course, is to the necessary use of experiments on animals The spirit which goes by the name of anti-vivisection was described as one of the enemies of the people. Happily, in this matter, we have all the help which the Government can give to us.

IT is reported in the *Times* that Mr. T W Bagshawe and Mr. M. C. Lester have returned to England after an adventurous wintering in the Antarctic. Landed at Andvord Bay on the west of Graham Land (lat. 64° 45′ S.) by a Norwegian whaler in December 1920, Messrs. Bagshawe and Lester hoped to be able to undertake some exploration in the interior of Graham Land; but the site of their base was ill-chosen for this purpose, and they were unable to do any survey beyond the immediate locality. Their work amplified the rough surveys of the *Belgica* on this coast in 1898. Meteorological observations were taken throughout the winter. From Mr. Bagshawe's account of the adventure it would appear that he and his companion were most inadequately supplied with stores and equipment for an Antarctic winter, having to improvise a hut from their boat with the help of canvas and packing-cases. For food they wisely relied largely on seals and penguins. Fortunately the west side of Graham Land has a relatively open winter climate. The men were rescued by a Norwegian whaler from Deception Island in December 1921.

AN exhibition of Egyptian ornaments, tools, and carvings belonging to the First Dynasty, and of numerous papyri of different ages, the fruits of a season's work by the British School of Archæology in Egypt, under the direction of Prof. W. M. Flinders Petrie, will be open at University College, Gower Street, until July 29. Admission is free and without ticket.

THE twentieth session of the International Congress of Americanists will be held in Rio de Janeiro on August 20-30 next, under the presidency of Dr. Joao Teixeiro Soares The arrangements are in the hands of a strong local committee. As the celebration of the centenary of Brazil's independence begins on September 7, it is anticipated that there will be a large attendance. The subjects which are to be discussed at the congress are the origin, history, languages, customs, and religions of the native races of America, the ancient monuments and archæology of America, and the history of the discovery and European occupation of America. At the close of the congress arrangements will be made for excursions to the States of Minas Geraes, St. Catherina, Espiritu Santo, and São Paolo. Members of the congress will be afforded an opportunity to return by way of Para, where there is, in the museum, the collection of ancient pottery from the island of Marajo, which is of great interest to students of American archæology. Arrangements have been made by the Royal Mail Steam Packet and Nelson lines for members of the congress to travel at reduced rates. Information

respecting the congress may be obtained from the Secretario Geral, XX Congresso de Americanistas, Sociedade de Geographia, Praça 15 de Novembre, No. 101, Rio de Janeiro.

SOME interesting points in the work of officials connected with scientific and technical bodies, especially in relation to the scientific and technical press, were raised in an address on the duties of secretaries, delivered by Mr. P. L. Marks at a meeting of the Circle of Scientific, Technical, and Trade Journalists on May 30. There are few men gifted with the power of presenting scientific knowledge in an easily assimilated form, and it is here that a really competent secretary reveals itself. Editors are busy men, often with a wide but not a detailed knowledge of scientific subjects, who require information conveyed within a small compass; and if a secretary, in issuing matter to the press, can select certain journals for individual treatment, providing them with matter closely allied or linked to their respective fields of operations, his efforts will not be vain This applies particularly to bodies the aim of which is the popularisation of science. The ideal secretary must be able to take a wide view and sanction some departure from the limits of absolute scientific truth, if essential to simplicity and popular appeal While rejecting fallacious statements—involving inaccuracy arising from ignorance rather than an effort after simplicity—such as are apt to creep into daily non-technical papers, it is not necessary to adhere to the standard rightly demanded in scientific transactions With regard to secretaries who exercise editorial functions in connexion with their societies, Mr Marks inclines to the view that no radical alteration in contributions or discussion should be permitted Nevertheless we think it advisable in the interests of a society that its transactions should not contain statements that are manifestly incorrect or absurd, or in conflict with its policy In general the authors of such remarks are open to correction, if tactfully conveyed A secretary of a scientific body may not receive high remuneration, may not even enjoy the esteem and appreciation he deserves, but he has the knowledge that by his work he is shaping the scientific destiny of the nation.

WITHIN recent years most of the leading industries have founded Research Associations, and in 1919 the Council of the Institute of Brewing decided to make provision for investigating problems of a general character in the brewing and allied industries To obtain the necessary funds for carrying out the scheme a new class of members, known as Research Fund Members, has been created. These members consist of firms who are invited to join the Institute at a minimum annual subscription of 10 guineas. At the end of 1921, the total subscriptions amounted to nearly 6000*l.* per annum, so that the scheme is now well in being. Two reports have already been issued, and particulars are given of the investigations so far carried out in connexion with hops, barley, and timber. An account is given of the experiments on breeding new varieties of hops at the South Eastern Agricultural College, Wye, and their testing on a commercial scale at the East Malling Research Station, under the direction of Mr. E. S. Salmon. Photographs and a detailed description of the kilns erected by the Institute at Beltring, Kent, for investigating the various factors involved in the drying of hops are also given in Report II. Manurial experiments on hops are being carried out at Chilham and Horsmonden by Mr. F. Ivo Neame and Mr. T. I. Nicolson respectively, while the chemical investigations are being conducted, under the direction of Dr. F. L. Pyman, at the College of Technology, Manchester. With regard to barley it is intended to make a systematic study of barley and malt from the agricultural, botanical, chemical, and physiological standpoints, and arrangements have been made for field trials, under the direction of Sir John Russell, of the Rothamsted Experimental Station, on farming conditions in East Suffolk, Lincolnshire, Somerset, Essex, Yorkshire, Norfolk, Shropshire, Wiltshire, and the East Lothians. Trials are also being made at the Rothamsted and Woburn Experimental Stations. Mr. H. F. E. Hulton has drawn up a report on the relation of the nitrogenous matters in barley to brewing value, while botanical and chemical investigations on timber for casks, with special reference to American oak, are being carried out at the Imperial College of Science and Technology, under the direction of Prof P. Groom and Prof. S. B. Schryver, respectively.

AT the meeting of the Royal Statistical Society on June 20, a paper was read by Mr. J. W. Verdier dealing with the statistics of shipping casualties and loss of life at sea Discussing the occupational risks run by seamen, the author gave comparative estimates, based on the recorded deaths by accidents in the five years ended 1913. The yearly death-rate among seamen was 4·05 per thousand employed, compared with 1·56 for underground workers in coal mines, and 0·59 for railway servants. It is estimated that the number of deaths per million man-hours of employment was 0·97 for seamen, 0·68 among underground workers in coal mines, and 0·20 among railway servants Mr Verdier also compared the accidents involving deaths of passengers on steam vessels with those on railways. Assuming that, in the foreign trade, sea passengers are at sea for twenty days on the average, and that railway passengers (excluding season ticket holders) are on the train for about an hour, then, in the period about 1900, the railway passengers' deaths were 0·12 per million passenger-hours, while the sea passengers' were 1·5, or more than twelve times as great In the period about 1910, the railway passengers' deaths were about 0·1 per million passenger-hours, and the sea passengers' 0·3, or three times as great, showing that there has been a general progress towards safety.

THE address prepared by Sir Robert Hadfield for the Sheffield Association of Metallurgists and Metallurgical Chemists last October has been published under the title of "The Work and Position of the

Metallurgical Chemist," and is illustrated by a number of plates. The address covers a very wide field, the history of metallurgical research being surveyed, with special reference to the part played by Sheffield workers. This is brought into relation with the general history of science, and with the early work of the Royal Society in establishing the experimental method of investigation The international character of metallurgical research is exemplified by a description of the new Japanese Institute for Steel Research, just opened at Sendai under the direction of Prof. Honda. The speaker's own work is dealt with, particularly in the application of manganese steel to the purposes of the war This aspect of metallurgy was illustrated by the exhibition of a very fine series of specimens of this alloy as employed in the arts of peace and war. The exhibition also included specimens of the author's other technical work, and books and other objects of historic interest. The plates are finely produced, and are of great interest.

ACCORDING to the June issue of the *Decimal Educator*, the official organ of the Decimal Association, the Association proposes to concentrate its efforts for the time being on securing an alteration of the value of the pound weight from 454 to 500 grams, that is, half a kilogram. The ounce of 16 to the pound would in the first instance be retained, so that 4 ounces would be 125 grams The new ton would be 2000 new pounds, equal to the metric ton and a little more than 1·5 per cent. greater than the present ton. All denominations between the pound and ton, such as hundredweights, quarters, and stones of all kinds, would be eliminated and intermediate weights expressed in pounds This decision will not interfere in any way with the movement, which has the support of bankers and chambers of commerce, for the change of the value of the penny to one-tenth of a shilling

THE Review of the work of the Rockefeller Foundation for 1921, compiled by the president, George E Vincent, has just been issued Grants have been made to numerous educational institutions for campaigns against hook-worm disease, malaria, yellow fever, and tuberculosis, for the promotion of the training of nurses; for libraries, fellowships, and other purposes. A sum of more than seven and a half million dollars has been expended on the world-wide activities of the Foundation.

THE Ministry of Agriculture, Industry, and Commerce of Brazil has just published the first number of a new journal, *Revista Mensal de Meteorologia*, which will be devoted to meteorological interests in that country. The review will be divided into (*a*) memoirs, etc.; (*b*) notes, reviews, and critiques; (*c*) bibliography; (*d*) notices; (*e*) papers by the Director of Meteorology. The first number contains an article on the applications of meteorology to everyday life, the report of the Director of Meteorology from June to December 1921, the reorganisation of the meteorological service in the Minas Geraes province of Brazil, notes from foreign sources, and a number of reviews, among other interesting features.

THE firm of Messrs. Pastorelli and Rapkin, Ltd., of 46 Hatton Garden, London, has forwarded to us a list of thermographs and hygrographs. The instruments are of two types, for meteorological observers and a stronger make for factory work, such as fruit preserving and drying, cold storage chambers, dye-works, wall paper printing, and other branches of industry Two patterns are recommended—the Peandar and the Edney. The former is suggested for meteorological observers and has a small, stem-divided thermometer fixed near the thermometric coil, so that the readings shown by the self-recording instrument can be compared and if necessary readjustment can be made. A pattern of the Edney is adapted as a hair hygrometer which records directly the percentage of humidity by the alterations in the length of a string of human hair The dry and wet bulb thermometers, known as Mason's hygrometer, have long maintained their utility. The instrument maker would improve the hygrometric results if he contrived that a good flow of air should be driven over the wet bulb, a consideration of growing interest on both sides of the Atlantic.

WE have received from the City Sale and Exchange, 81 Aldersgate Street, E C 1, the catalogue of the Koristka microscopes and accessories, for which they are sole British agents. Several different types of microscope stands are listed, from simple students' models to instruments suitable for research work and photomicrography A travelling portable folding microscope is also supplied, which, with objectives, etc., weighs less than 7 lb and folds into a leather case measuring $7\frac{3}{4}\times5\times7$ in. Photomicrographic cameras, warm and detachable mechanical stages, dark-ground illuminators, microtomes, hand lenses, and other accessories are also included in the catalogue. A complete series of apochromatic, semi-apochromatic, and achromatic objectives are manufactured by the firm. The Koristka Co has a deservedly high reputation both for their mechanical and for their optical work, and the prices charged compare favourably with those of other firms.

MESSRS. W. HEFFER & SONS, Ltd, Cambridge, have in the press "Cements and Artificial Stones: A Descriptive Catalogue of the Specimens in the Sedgwick Museum, Cambridge," by the late J. Watson, edited by Dr. R. H. Rastall, in which will be found a brief history of the origin and development of the cement industry, and notes on the manufacture and uses of the various kinds of cement, concrete, and artificial stone which are exhibited in the economic department of the Sedgwick Museum of Geology, at Cambridge. The same publishers also promise "An Introduction to Forecasting Weather," by P. R. Zealley, which aims at presenting in a clear and simple manner the principles on which weather forecasting is based.

Our Astronomical Column.

EPHEMERIS OF SKJELLERUP'S COMET, 1922 *b*.—This ephemeris is for Greenwich midnight from the elliptical elements given in NATURE of July 1, p 20, which are approximately true

	R A			N Decl			R A			N Decl
	H.	M.	S.				H	M	S	
July 6	15	58	43	37° 53′		July 14	16	37	46	31° 17′
8	16	10	1	36 19		16	16	45	15	30 16
10	16	20	14	34 45		18	16	53	1	28 48
12	16	29	30	33 13		20	16	59	32	27 29

During the interval, June 30–July 20, log *r* increases from 0·0480 to 0·1131, log Δ from 9·5124 to 9·6830 Owing to its short period, it is important to follow it as long as possible in order to facilitate its recovery on its return

PROF PLASKETT'S MASSIVE STAR —Some further particulars about this star (see NATURE, June 17, p. 791) may be of interest It is in Monoceros, in the middle of the Galaxy, its place for 1900 being R A 6^h $32·0^m$, N Decl 6° 13′, visual magnitude 6·06 The spectral type in the Henry Draper Catalogue is Bop, but Plaskett prefers Oe5 the orbital velocities of the two components are 206 38, and 246 7 km /sec, the period 14·414 days, the eccentricity 0·0349, the minimum masses of the components 75 6 sun and 63·3 sun From the non-occurrence of eclipses it is inferred that the orbit is at least 17° from the edgeways position, and the masses 14 per cent greater than the minimum values The centre of gravity is receding at 23·94 km /sec The H and K lines of calcium show no orbital motion, but a steady recession of 15 9 km /sec, which is exactly the amount of the sun's resolved motion, so that the calcium is at rest with respect to the star-system, a result obtained in other spectroscopic binaries The following estimates are given of the star's size and distance density 0 01 of sun's, surface brightness 4 magnitudes in excess of sun's, diameters 20 and 18 times sun's, distance between centres 65 sun-diameters, distance from the earth 10,000 light-years, absolute magnitude of brighter component 5 65 It is noted that the recession of the centre of gravity, corrected for solar motion, is 8 km /sec, with the estimated dimensions and masses, the Einstein spectral shift would account for 2·8 km /sec of this quantity

Since this star, the most massive known, lies so near the mean galactic circle, it may be suggested as a suitable zero of galactic longitude, it seems wrong to use the terrestrial equator as the zero point, for it reintroduces precession, which it is the object of galactic co-ordinates to avoid

ORIGIN OF THE ASTEROIDS —Dr K Hirayama discusses this old problem once more in the June number of *Scientia* He recalls the early suggestion of an exploded planet, and its abandonment when the wide range of the orbits became known He then mentions the rival hypotheses, one by one, showing that they too have difficulties Thus many have suggested that it was the disturbing action of Jupiter that prevented the nebulous ring, assumed to have existed in this region, from forming into a single planet, but he notes that the four great satellites of Jupiter are quite near it, and yet much larger than any of the asteroids. He also notes objections to the theory that the asteroids came from a distance, and had been captured by Jupiter, like the short-period comets The orbits of many of them do not approach near enough to Jupiter for this, and their major axes are almost free from perturbation

Dr. Hirayama himself favours a theory, put forward by Young, which invokes not one but several explosions. Each "family" of asteroids, of which many have been traced, is explained as the result of an explosion of a single body In support of this view he refers to the rapid and irregular light-variation of many asteroids, notably Eros He supposes that they are irregular, angular fragments, their own gravitation being too weak to compel them to take a spherical form, if they were rotating about an axis that was not a principal axis, both the position of the axis in the body and the period of rotation would vary, this agrees with observed facts It would be possible, by assuming a sufficient number of explosions, to trace the whole system of asteroids to a single primitive planet As the whole mass of the known asteroids is only some 1/2000 of that of the earth, he thinks it possible that many fragments may have been absorbed by the sun and Jupiter, and in conclusion suggests a similar origin for the ring of Saturn, noting the many resemblances between it and the asteroid system

NORMAN LOCKYER OBSERVATORY (1921 1922) —In his report for the year 1921, April 1, to 1922, March 31, Dr W J S Lockyer, the director of the Observatory, directs attention to several advances which will be of interest to observers who have followed the progress of this new institution

At present the greater part of the work is confined to stellar investigations, and observations were made on 137 of the 149 nights which were sufficiently clear. The McClean telescope, with the 12-inch prismatic camera, has been used for obtaining stellar spectra for classification and parallax determinations. During the year 654 negatives have been secured

With the 9-inch Kensington prismatic camera 79 negatives have been obtained in the progress of a scheme to photograph the spectra of all stars down to about the fourth magnitude Special attention is being paid to large-scale spectra of standard giant and dwarf stars of types F to M These are being examined by Adams' method for the determination of stellar parallax At the present time 1200 negatives are available, and 370 have been measured, giving preliminary curves showing correlations between absolute magnitude and line-intensity differences A wedge method of determining the line intensities has been devised, and details of the procedure have been published

The routine classification of stellar spectra by means of the Kensington nomenclature of generic class names has been discontinued, and the Harvard system, based on numerical measures of line-intensities in the spectra, combined with the separation of stars into groups of increasing (giant) and decreasing (dwarf) temperatures, has been adopted in its place. For laboratory investigations a 10-feet Littrow spectrograph, by Hilger, has been presented to the Observatory by Lady Lockyer

It is evident that an observatory of this character, with extensive instrumental equipment, is well suited to further the prosecution of investigations beyond those covered by the immediate routine, and it is pleasant to note that during the past year two student observers have been encouraged to spend short periods at the Observatory.

Research Items.

THE PEOPLING OF ASIA.—Dr. Aleš Hrdlička, the distinguished American ethnologist, contributes to the Proceedings of the American Philosophical Society (vol. lx. No. 4) an important paper on the peopling of Asia, which "constitutes one of the greatest problems of anthropology." He concludes that the cradle of humanity was essentially south-western Europe, with, later, the Mediterranean basin, Western Asia, and Africa It is primarily from Europe and secondarily from these regions that the earth was peopled, and this peopling was comparatively recent Early man was unable to people the globe owing to his insufficient effectiveness, and until the end of glacial times and his old stone culture he had evidently all he could do to preserve mere existence. Only an advance in culture could enable him to control his environment and secure a steady surplus of births over deaths. The cause of man's peopling of the world was not a mere wish to do so, but the necessity arising from growing numbers and correspondingly decreasing supply of food It was this which eventually led to agriculture. This spreading over the globe was conditioned by three great laws—movement in the direction of least resistance, movement in the direction of the greatest prospects; movement due to a force from behind, or compulsion.

COINS OF CROESUS.—A party of American archaeologists working in Anatolia, among the ruins of Sardis, has discovered thirty gold staters of Croesus, dating from the period between 561 B.C., when Croesus ascended the throne, and 546 B.C., when his capital was taken by Cyrus, king of Persia They are in excellent condition, although some are a little worn The only five staters hitherto known to exist are in the British Museum, but only one is in good condition Dr Leslie Shear, the archaeologist of Columbia University, who has brought the news of this discovery, states that the coins were found in a small earthen vessel in the ruins of a tomb, where they may have been hidden by a Lydian merchant during the siege of the city by Cyrus The coins, which are in charge of the discoverers, cannot be brought to America until the right of ownership is decided, but according to the treaty of Sèvres, such articles discovered in territory assigned to Greece should be divided, half to the Constantinople Museum, and half to the finders The coins of Croesus are made of electrum, or mixed gold and silver, and are of two types, weighing respectively 8·40 grams and 11·20 grams. Those hitherto discovered are oblong in shape, bearing the heads of a lion and a bull.

AN UPPER PALAEOLITHIC STATION, AVELINE'S HOLE.—The report of the Spelaeological Society, University of Bristol, for 1920–21, describes the excavation of Aveline's Hole, a rift cavern in the mountain limestone forming the east wall of Burrington Combe. It was first discovered in 1797, and Rutter, writing in 1829, states that nearly 50 skeletons were found lying with their heads under the north side of the rock and feet extended towards the centre of the cave. The Society commenced work in 1919, and it has continued regularly ever since Associated with numerous animal remains characteristic of the late Pleistocene were found artifacts of the early Tardenoisian or late Magdalenian periods, agreeing with the determination of the fauna. The human remains belong to the same horizon, since no trace of polished stone or metal weapons, or of any culture other than late Palaeolithic, has been found in the cave, which seems to have been closed with a block of stone very shortly after the bodies were deposited. The people whose remains were found were contemporaries with the late Magdalenians of southern France, and their culture was Tardenoisian, possibly a transitional stage between the Magdalenian and Aurignacian, an industrial evolution which may have taken place in England.

THE RED CRAG FLINTS OF FOXHALL.—In the June issue of *Man* Mr. S Hazzledine Warren discusses the question of the signs of human handiwork on flints from the Red Crag, Foxhall. He sums up his conclusions as follows: "The Foxhall flints give us another instance of the association of striated surfaces with exclusively mechanical characters in the flakes themselves and in their trimmed edges And that this association and limitation to the mechanical group of forms does not constitute an unsatisfactory, or doubtful case of not proven, but (from the point of view of a human industry) a definite, complete, and conclusive case of 'proven not'."

PARASITIC COPEPODS.—Mr. C B. Wilson contributes to the Proceedings U S Nat Mus (vol. 60, art 5, 1922, 100 pp., 13 plates) his sixteenth paper on the parasitic copepods in the museum collection. The present paper is devoted to the Dichelesthiidæ, which are parasites on the gills of fishes, but do not burrow into the tissues of their host after the manner of the Lernæidæ, though one genus, Cætrodes, produces irritation of the gill tissue, causing the latter to grow up as a flap or fold entirely surrounding the body of the copepod and holding it securely in place. Other genera provoke irritation by their prehensile claws sufficient to cause the gill tissue to grow up around the claws The transformations common in the Lernæidæ are not met with in the Dichelesthiidæ No material change in the bodily form or structure of these copepods takes place subsequent to their attachment The author gives a history of the family, a short account of the ecology, external features, and internal organs, systematic descriptions of and keys to the 20 genera and 107 species The only stage of development known for any of the members of this family is the nauplius, and a description of the known nauplii is given In the account of the internal structure is included a short note on the closed vascular system of the genus Lernanthropus, which consists of two ventral longitudinal trunks below the intestine, and a single dorsal trunk above the intestine, from all three of which branches pass to the appendages, and there is a network of capillaries over the dorsal surface and in the laminate swimming legs No part of this system is connected with the body cavity (hæmocœl) The trunks and capillaries contain a yellowish red fluid which streams backwards and forwards under the influence of the peristaltic movements of the alimentary canal. Neither blood corpuscles "nor any other definite constituents" were found in this fluid

INTERSEXUALITY.—Dr. R. de la Vaulx has given (*Revue générale des Sciences*, March 30, 1922) a short review of recent work on intersexuality — the occurrence of examples intermediate between the normal male and female of the species. Some of these are intersexes, others are more correctly termed gynandromorphs The former are intermediate in structure between male and female, and are the same on both sides, whereas gynandromorphs consist typically of a mosaic of male and female structures—often one side is male and the other female—and these cases are comparatively rare. The author cites examples of intersexuality from invertebrates—the

butterfly *Lymantria dispar*, the lice *Pediculus humanus* vars. *capitis* and *corporis*, Gammarus and Drosophila, and describes some examples from his own cultures of Daphnia. In Daphnia the intersexes appear not among hybrid examples as in the other cases cited above, but arise during parthenogenetic reproduction, and, on the whole, they seem to have been biassed originally towards the male sex and then to have been secondarily feminised. Dr. Vaulx proceeds to discuss whether the intersexual condition is due to the action of two determining factors acting simultaneously or to two forces, *e.g.* hormones, working successively, and remarks that sex appears to depend on numerous factors or elements, and it has hitherto been found possible to investigate only some of these. He considers that the facts examined lead to two inferences: (*a*) That sex does not depend on discontinuous factors, or the absence or presence of something as chromosome formulæ suggest, but on complex causes resulting in continuous variation; (*b*) every unisexual individual possesses potentially the attributes of the other sex, and these may be revealed under certain conditions; it does not seem that one sex can be really homozygous.

Arctic Rotifera.—In a short account of the Rotifera of the Canadian Arctic Expedition (Report, vol. viii) Mr H. K. Harring records 64 species, four of which are new, among which is a pelagic Synchæta—an addition to the extremely small number of rotifers known to exist in the open ocean in waters of normal salinity. The total absence of the genus Brachionus so abundant elsewhere is noteworthy.

Carbonaceous Material in Oilshale.—Mr E. H. Cunningham Craig's recent paper on kukkersite, the oilshale of Esthonia (read before the Institute of Petroleum Technologists on May 9), reopens—among other controversial matters—the question of the origin of the carbonaceous material present in oilshale, a problem upon which the study of this particular deposit may be destined to shed considerable light. The shale is of Ordovician age, and forms part of a Lower Palæozoic sequence remarkable alike for its sedimentary characters and its simplicity of geological structure. Palæontologically the shale has received recent attention from Mr H. Bekker, who has not only described the Kukkers stage (C_2), but has given some account of the lithology and mode of deposition of the deposit, together with his views on the origin of the bituminous matter present. His conclusions differ in many respects from those of Mr Cunningham Craig, the latter regarding the deposit as a relic oil-field, the former stressing the importance of the part played by diatomaceous algæ and bacteria under a changing environment. Mr Cunningham Craig regards the shale as being formed by impregnation with inspissated petroleum, derived from the underlying Cambrian beds, a theory presenting many difficulties, some at least as formidable as those possibly occasioned by the phytoplanctonic theory. Apart from this, the commercial possibilities of the shale are extremely favourable, though one gathers from Mr Cunningham Craig's remarks that the type of retort used in the past has not been the success anticipated. He estimates the available reserves as 1000 million tons. The yield of oil, at present varying from 40 to 50 gallons per ton, could easily be raised to 70 or even 80 gallons per ton, the oil having a specific gravity not higher than 0·93 and containing very little sulphur. Labour is cheap, and the cost of working and refining the shale should not be great. Altogether Esthonia possesses a deposit valuable alike from scientific and economic standpoints, and the progress of development of this shale will be watched with wide interest.

The Drought of 1921.—A communication is given in the Quarterly Journal of the Royal Meteorological Society for April by Mr. C. E. P. Brooks and Mr. J. Glasspoole, of the Meteorological Office, on the drought of 1921, dealt with under the headings of the rainfall of the British Isles and the causes of drought in the British Isles. The year 1921 was in certain areas a year of unprecedentedly small rainfall. The only years since 1850 at all comparable with 1921 were 1854, 1864, 1870, and 1887. In 1854 the deficiency of rain reached its maximum in the south-east, where it was more than 30 per cent., to the east of a line roughly from Bournemouth to Lincoln. In 1864 the maximum deficiency exceeded 30 per cent., over large areas along the east coast and in Devon and Herefordshire. In 1870 the greatest deficiency, exceeding 30 per cent., occurred in the central plain of Scotland and locally in the south and centre of England. In 1887 deficiencies of more than 30 per cent were widespread in the centre of the British Isles, especially in the south-west of Ireland and in a broad band across England from Southport to Hull. For England and Wales 1921 was the driest year since 1850, while for the British Isles as a whole, only one year, 1887, was slightly drier. Indeed, 1921 was probably the driest year since 1788 for England and Wales. A comparison is also made between the general rainfall in 1921 with that of other dry periods of three to nine months' duration, and maps are given showing the several percentages. In the second part of the communication the drought is considered as related to abnormalities in the circulation of the atmosphere. Droughts in the British Isles are closely related to the establishment and the persistence of local anticyclonic conditions, and an attempt is made to find how these abnormalities are related to others in different parts of the world. Maps of the world showing deviations of pressure from normal during the chief periods of drought in the British Isles are given for the occurrences since 1864. Generally speaking, low pressure over the polar regions appears to be an essential feature of drought in the British Isles, and in consequence is considered to be an important factor in forecasting droughts.

Focal Depths of Earthquakes.—The first number of the Geophysical Supplement to the Monthly Notices of the Royal Astronomical Society (for March 1922) consists of a valuable paper by Prof. H. H. Turner on the arrival of earthquake waves at the antipodes and on the measurement of the focal depth of an earthquake. To a distance $\Delta = 90°$, the usual tables give good results for the arrival of the primary waves of an earthquake. Beyond this distance there is some uncertainty, but near the antipodes of the epicentre the records again become clear and regular. From 130° to 180° the time of traverse in seconds is given approximately by the expression

$$1217 - (180 - \Delta)^2 \times 0{\cdot}0235$$

For a single earthquake, the mean error of the expression is about ± 3·5 secs., but for the great earthquakes from 1913 to 1916 it is about ± 14 secs. There is thus a systematic error for each particular earthquake ascribable to a particular depth of focus, which must be greater than 0·021, and may have a value such as 0·04, of the earth's radius. Prof. Turner suggests that the antipodes of the epicentre should be called the hypocentre, a term which has been used for the last thirty years to denote the seismic focus. In Italy its use for this purpose is practically universal. Outside that country, it has been adopted by M. de Montessus de Ballore and Prince Galitzin.

Coral Reefs of the Louisiade Archipelago.[1]

By Prof. W. M. DAVIS, Harvard University.

THE Louisiade archipelago, consisting of four medium-sized and many small islands east of New Guinea, is well represented on British Admiralty chart 2124 on a scale of about 1 : 280,000; chart 1477 shows part of the archipelago in greater detail on a scale of about 1 : 140,000. According to brief accounts by Macgillivray,[2] Thomson,[3] and Maitland,[4] the chief islands are composed of steeply inclined and deeply eroded schists and slates, traversed by quartz veins; they are evidently parts of the mountain range that extends for hundreds of miles along the northern coast of New Guinea, from which they have been separated by strong subsidence after having been eroded to about their present form. The largest island is Tagula, 30 miles in length east-west along the trend of its schists, and 8 or 9 miles in width; it has an embayed shore line and rises in ten summits to heights of from 1330 to 2645 feet. Near by is the Calvados chain of satellite islands, which begins about 7 miles north of the middle of Tagula and extends 70 miles westward; it includes more than a score of members, the largest having a length of 11 miles and a height of 1110 feet. Tagula and its chain of satellites are enclosed by a superb barrier reef, the irregularly oval circuit of which measures 112 miles in east-west diameter by about 30 miles north-south; it is unquestionably one of the finest reefs of its kind in the whole Pacific.

The smaller islands of Rossel to the east and Deboyne to the north-west of Tagula are also surrounded by sea-level reefs, partly as fringes but mostly barriers. Misima, north of Deboyne, measuring 22 by 10 miles and reaching 3500 feet in height, is peculiar in having no sea-level reefs and in descending rapidly into deep water, although it is terraced by unconformable reefs at various altitudes. It has therefore suffered a recent uplift after having previously taken part in the subsidence which characterises the other islands; but its subsidence must have been more rapid than theirs as it has no widely developed barrier-reef lagoon floor, either near present sea-level or above or below it.

The Tagula barrier reef and its great lagoon merit special attention from the evidence that they give regarding the verity of certain coral-reef theories. The reef is best developed around the south-eastern or windward half of its great oval circuit, where it is interrupted by only four passes in a curved distance of 110 miles, and where the reef flat has a width of 2 or 3 miles. The north-western or leeward half of the barrier is strikingly discontinuous and consists in part of small patches, but more commonly of atoll-like loops and rings, thirty-six in number, from 1 to 5 miles in diameter, enclosing little lagoons from 10 to 17 fathoms in depth. The loops and rings of this half of the circuit are separated by as many passages, from ½ to 3 miles wide and from 15 to 35 fathoms deep. But the most remarkable features of this part of the barrier are the small or minute but high islands, here to be referred to as outposts, which rise in twenty-two of the reef loops. The largest of them is only 4 miles in diameter; their heights vary from 40 to 530 feet. Some of them appear to consist of schist, judging by their trends; but according to Maitland some of the others are volcanic and a few are made of limestone. As elements of a barrier reef, these small but high outpost islands are so exceptional as to be almost unique.

The great Tagula lagoon is divided by the Calvados chain of satellite islands into a smaller northern and a larger southern compartment; the northern compartment is of triangular outline, with its base along the dividing chain and its vertex about 10 miles away at the most northern point of the reef; it occupies about one-sixth of the entire reef-enclosed space, which is about 2000 square miles in total area. The southern compartment measures 20 miles across, and extends east-west along the whole 112 miles of the lagoon length; it occupies about four-sixths of the enclosed area; the remaining sixth is taken by Tagula and the satellite islands. The greater part of the lagoon floor in both compartments is a gently undulating plain usually from 25 to 35 fathoms in depth. The depth of the southern compartment increases gradually for a moderate distance from the broad enclosing reef, and more rapidly from the islands of the Calvados chain. The greatest depths, 46 fathoms in the southern or windward compartment and 49 fathoms in the northern or leeward compartment, are in both cases found much nearer the dividing island chain than the outer barrier reef. The exterior slopes of the reef fall off rapidly into deep water; a few soundings show depths of more than 600 fathoms two miles from the reef on the west and north-west.

A correct theory of the Louisiade reefs must take account of the great subsidence that the islands have suffered. It would therefore appear that the present sea-level reefs should be regarded as the successors of a long-lived series of upgrowing reefs which have been formed, essentially according to Darwin's theory, by more or less intermittent upgrowth from earlier shore lines of the subsiding mountainous islands. It is probable that where the island slopes were very steep, the reefs, presumably inclining inwards as they grew up, remained attached to the shore as fringes; conversely, where the island slopes were gentler or where low slopes have been broadly submerged, the reefs now form offshore barriers. During the upgrowth of the reefs, some of their detritus must have been swept seaward, to form the submarine talus that descends into deep water; the rest must have been swept into the lagoons, where, reinforced by local organic detritus and probably in smaller measure by detritus from the islands, it appears to have aggraded the "moats" between the reefs and the islands.

It thus seems that the formation of the great undermass of the Louisiade reefs, and especially of the Tagula reef, may well have been consistent with the conditions and processes of Darwin's theory. It should be added that the evidence for the strong subsidence of the Louisiade islands is, in view of their constitution, much more direct than that furnished for the similar subsidence of most reef-encircled volcanic islands in the central Pacific; and that this well-certified subsidence of the foundations on which the Louisiade reef-masses have been built up gives immensely greater support for Darwin's theory than is afforded by the atolls of the open Pacific, where the occurrence of subsidence is indicated only by indirect evidence. It remains to inquire whether the Louisiade sea-level reefs, which surmount the great undermass, accord with or contradict other coral-reef theories, especially the newly framed Glacial-control theory of sea-level reefs. This theory was proposed

[3] B. H. Thomson, "New Guinea: Narrative of an Exploring Expedition to the Louisiade and D'Entrecasteaux Islands," Proc. Roy. Geogr. Soc., 11, 1889 (525-542).

[4] A. G. Maitland, "Geological Observations in British New Guinea," Queensland, Geol. Surv. Pub., 85, 1892. "Salient Geological Features of New Guinea," Journ. W. Austral. N. H. Soc., 2, 1905 (32-56).

more particularly to account for the atolls and barrier reefs of the supposedly quiescent central Pacific than for the barrier reefs of much disturbed regions like the Louisiade archipelago; nevertheless the Tagula reef in particular affords critical evidence against that theory, as will be made clear by the following considerations.

The Glacial-control theory appears to be based on the conviction that it is the smooth lagoon floors rather than their enclosing reefs which are most in need of explanation, and that the bathymetric relation of the lagoon floors to the level of the ocean reached by the enclosing reefs is normally so nearly constant in all the coral seas that their explanation by Darwin's theory in terms of reef upgrowth and lagoon aggradation on subsiding foundations of irregular form is impossible. A long period of nearly perfect stability of the mid-ocean floor is therefore assumed, although instability is admitted for islands in the south-western Pacific; and instead of postulating that lagoon floors represent "moats" that have been heavily aggraded behind the upgrowing reefs during the subsidence of their foundations, a series of ingenious suppositions is invented, of which the chief are that during Preglacial time many still-standing islands, more or less reef-surrounded, were either worn down to low relief by subaerial erosion or cut down to shallow platforms by marine abrasion, that during the Glacial epochs of the Glacial period the ocean surface was lowered by about 35 fathoms by the withdrawal of water to form continental ice sheets; that the surface waters of the ocean were then so chilled as to kill or greatly to weaken reef-building organisms; that islands were then attacked by the waves, which cut low-level benches around them if they were high, or if they were low completely truncated them in platforms at a depth of 35 to 40 fathoms below normal sea level; that as the waters warmed and rose, reefs grew up on the margins of the benches and platforms, whereupon the lagoons behind them were moderately aggraded; and that the thickness of the aggrading deposits is greater, and consequently the lagoon depth is less in small than in large lagoons, because the detritus supplied from a linear front-foot of a reef has a smaller interior sector to aggrade in a small lagoon than in a large one. In brief, the long-continued stability of reef foundations and the abrasion of sub-lagoon platforms upon them are leading factors of the Glacial-control theory.

It should be noted here that neither the stability of reef foundations nor the abrasion of sub-lagoon platforms is proved by any direct evidence, both of these leading factors are, like the subsidence of atoll foundations in Darwin's theory, assumed because they are thought to be necessary for the explanation of observed facts, and both assumptions are believed to be true because of the apparent success of the explanation that they provide. Hence if it be shown, even in a single instance, that a lagoon floor of typical form and depth has been produced around an island which provides independent evidence contradictory to stability and abrasion and, indeed, requires strong subsidence, the fundamental assumptions of the Glacial-control theory will be seriously invalidated.

The bearing of Tagula reef and lagoon on the Glacial-control theory may now be apprehended. Tagula is, as has already been shown, not in a region of long-continued and nearly perfect stability, but in one of marked instability, and as will next be shown, it has not suffered abrasion by the lowered ocean; yet its lagoon floor is smooth, and of a depth accordant with that of other large lagoons in various parts of the Pacific. Hence long-continued stability and extensive low-level abrasion are not essential factors in the production of this fine example of a barrier-reef lagoon floor. But if these factors are not essential in Tagula, they should not be regarded as essential anywhere else; and their adoption as the leading postulates of the Glacial-control theory is therefore unnecessary; flatness of lagoon floors and their accordant depths may be explained elsewhere as well as in Tagula as the result of long-continued aggradation on subsiding foundations of uneven surface.

The evidence that Tagula has not suffered abrasion by the low Glacial ocean, and hence that the reef-building organisms around Tagula were not seriously weakened by the lowered temperatures of the lowered ocean in the Glacial epochs, is found partly in the absence of chartered cliffs on the shores of the main island where the barrier reef becomes a fringe, partly in the absence of similar cliffs on the exposed sides of the satellite islands at either end of the Calvados chain where it approaches the barrier reef, and partly in the presence of the outpost islands in the barrier-reef loops around the northern lagoon compartment.

As to the first line of evidence based on the absence of cliffs on Tagula. If abrasion by the lowered ocean had operated long enough to cut a platform 10 or 20 miles wide beneath the present floor of the southern compartment, it ought at the same time to have cut spur-end cliffs on the north shore of the main island, where the defending reef is a fringe only half a mile wide; and these cliffs ought still to show the upper part of their faces as plunging cliffs, now that the ocean has resumed its normal level; but the charts show no such cliffs.

The second line of evidence based on the absence of cliffs on the Calvados islands is similarly argued. It may be added that the absence of cliffs at these significant points on the charts of the Louisiade islands does not appear to be due to poor charting; for on the coast of Misima, where Maitland observed the white limestone scarps of elevated reefs, the charts clearly show a shore cliff, and a legend is printed along it, "Cliffs 100 feet high."

As to the third line of evidence: The little outpost islands are so numerous in the Tagula barrier-reef loops around the northern lagoon compartment and around the western part of the southern compartment that it seems unreasonable to believe the waves of the lowered Glacial ocean could have cut their way behind the outposts efficiently enough to abrade a platform 10 miles in width. Not only so, the outpost islands show no sign of having cliffs on their outer sides. One of them, Utian, a mile across and 480 feet high, is reported by Maitland to consist of volcanic rocks; but it is not a young volcanic cone built up in Postglacial time, for the chart shows it to have well-dissected form, with three slender points enclosing two small bays turned toward the outer ocean, yet the points are not cut back in plunging cliffs. Another outpost not far away is said by the same observer to consist of limestone; this island cannot have been made and elevated since an assumed platform was abraded, for the height of the island, 530 feet, is so great that in such case the platform thereabouts ought to be more or less emerged; and it cannot have been made and raised before the platform was cut, for in such case the limestone ought to have been consumed by the waves that cut the platform.

The small outpost islands of the Tagula barrier reef therefore give strong confirmation of the evidence against abrasion derived from the absence of plunging cliffs on the north side of the main islands and on the terminal members of the Calvados chain. But if the northern compartment of the Tagula lagoon,

which alone is as large as many an atoll, is thus shown not to be underlaid by an abraded platform, there is no sufficient reason for thinking that the southern compartment, or indeed any other barrier reef or atoll lagoon in the whole Pacific, has any such smoothly prepared foundation. Surely if the flatness of the floor and its normal depth in both compartments of the Tagula lagoon have been brought about in a region of instability, and without the aid of abrasion in furnishing a smooth sub-lagoon platform, there is no sufficient reason for assuming that other flat lagoon floors of ordinary depth can have been prepared only on smooth platforms abraded at a standard depth across still-standing islands. It is possible that the Glacial lowering of the ocean surface by a moderate amount may have contributed, in a manner that I have suggested elsewhere,[5] to the production of many lagoon floors 30 or 40 fathoms in depth, but Glacial changes of ocean level do not seem otherwise to have left recognisable marks of their occurrence in the Louisiade archipelago. Crustal deformation has been dominant, and the great changes of shore lines thus determined appear to have been merely played upon by the inferred oscillations of ocean level during the Glacial period.

This discussion is believed to show that, apart from such changes of ocean level as are inherently probable although they are not well-known either in amount or in effects, the assumptions of the Glacial-control theory are not applicable in the production of Tagula reef and lagoon floor, and hence we may fairly conclude that these assumptions are not essential to the production of similar reefs and lagoon floors elsewhere. This argument, in which the evidence furnished by one outspoken witness for Darwin's theory and against the Glacial-control theory is given wide application, would not be valid if other witnesses were equally outspoken elsewhere against Darwin's theory and for the Glacial-control theory; but such is not the case. It must be remembered that the two main postulates of the Glacial-control theory, namely, long-continued stability of reef foundations in the mid-Pacific and the abrasion of sub-lagoon platforms by the lowered Glacial ocean, are not based on direct evidence but are assumed because they are supposed to be necessary for the explanation of smooth lagoon floors of standard depths. Not a single example of an abraded platform has been discovered under recently uplifted reefs; and a large number of mid-Pacific islands which have a decipherable recent history are found not to have been long stable but to have suffered various changes of level. In other words, where other outspoken witnesses are found, their testimony is, like that of Tagula, for Darwin's theory of upgrowing reefs on subsiding foundations of whatever shape. A large number of examples of this kind could be adduced if space permitted.

But although the inhibition of reef growth and the resulting abrasion of low-level platforms by the Glacial ocean thus appear to be excluded from the greater part of the coral seas, it is highly probable that reef-building organisms may have been weakened or killed and that abrasion of platforms may have taken place around islands near the margin of the coral seas; and at least some of those islands ought now to show plunging cliffs in evidence of their possession of submerged platforms, but even there the islands need not have been stable. This aspect of the coral-reef problem is examined in an essay submitted to the Geological Society of America for publication in its Bulletin.

[5] "Problems associated with the Study of Coral Reef," *Sci. Monthly*, 2, 1916 (505).

Root Respiration.[1]

ALTHOUGH so much work has been done on the question of root respiration, it is only within the last few years that the importance of the air content of the soil in this connexion has been clearly demonstrated. With the growth of ecological work has come the indication that this air content is a primary factor in many habitats and a controlling one in wet soil and water, but even yet this is not generally recognised.

Mr. F. E. Clements has endeavoured to clear the ground for further research in this direction by summarising the available information in all its aspects. From the time of Mayou (1668) the necessity of oxygen for root activity has been recognised, and numerous investigations have since added to the bulk of evidence with studies of germination, anaerobic respiration, and the respiratory behaviour of underground parts other than roots. The excretion of carbon-dioxide by the roots was first noted by Hales (1727), but the possible excretion of other substances is still a matter of controversy at the present day. Molisch first showed that roots exhibit the phenomenon of aerotropism or response to different concentrations of various gases. This is of great significance in plants inhabiting bogs and swampy land, as in order to obtain the oxygen necessary for respiration they develop aerotropic roots which run horizontally above the oxygen-free swamp soil, as in Alnus, or rise vertically in the air, as in Avicennia.

The composition of the soil air varies considerably with the nature of the soil, time of year, and seasonal changes, and is also affected by cultivation and plant growth, which increase the carbon-dioxide and diminish the oxygen in proportion. It has been suggested by Bristol that the presence of algæ may also affect the soil gases.

Anaerobic respiration is of much significance in connexion with reduced oxygen supply. The general effect of the reduction or absence of oxygen on respiration is to reduce its intensity, but respiration under anaerobic conditions differs with the species. Carbon-dioxide and alcohol are the regular products of such respiration, which is consequently regarded by most investigators as essentially identical with alcoholic fermentation when carbohydrates are present. Under certain conditions acetic, formic, and lactic acids are excreted from the roots and other parts of flowering plants. After considering the relation of photosynthesis, transpiration, and germination to oxygen supply, Mr. Clements enunciates the general rule that growth is decreased or prevented by the absence of oxygen. The movement of protoplasm in plant cells is stopped, and practically all tropistic responses are suppressed.

Field studies of aeration, approached from the agricultural, pathological, and ecological standpoints, corroborate the results of physiological investigation as to the basic importance of oxygen for root activity and the injury wrought by the accumulation of carbon-dioxide. The practical importance of this appears most strikingly in irrigated regions where the common practice involves the use of too much water, with consequent economic loss, due to the production of an oxygen deficit in the soil.

[1] "Aeration and Air Content: the Rôle of Oxygen in Root Activity," by Frederic E. Clements. Pp. 183. (Publication 315.) (Washington: Carnegie Institution, 1921.) 2 dollars.

The problem of soil aeration and the way in which it works injury to plants is much under discussion, but it appears certain that in some soils the lack of oxygen and the accumulation of carbon dioxide are primary factors, while the organic acids and salts arising from anærobiosis may play some part. In other cases acidity brings salts of aluminium, iron, or manganese into solution, which then exert a toxic effect.

Finally, after putting forward the present position of affairs with regard to toxic exudates and soil toxins, the author concludes his valuable survey with a comprehensive bibliography which contains more than seven hundred references. W. E. B.

Radio Direction Finding in Flying Machines.

THERE is little doubt that radio direction finders and other radio devices will soon be in regular use to enable aeroplanes to land at night, during fogs or at other times of poor visibility. The usual method is to transmit signals from an antenna in the landing field to the direction-finder on the aeroplane. This, however, gives merely the direction of the landing-field and provides no indication to the navigator of his distance from his destination.

Some years ago the Bureau of Standards in America experimented with induction signalling. A large horizontal single turn coil, 600 by 800 feet, was erected at the landing-stage. It was tuned to resonance at a frequency of 500 so that it produced a very powerful alternating magnetic field over a wide area in the neighbourhood. It was found that induction effects could be detected at considerable distances when the aeroplane was at a low altitude, but at the height of a mile they could be detected only throughout a small area directly over the coil. The tests showed that what was wanted was a hollow conical beam of radiation, the vertex of the beam being on the landing ground. At low altitudes it was very important that the signal should be audible over only a very limited range.

This has been effected by means of two equal coaxial coils with their planes horizontal and at different altitudes. The current, which has a radio-frequency of 300,000, flows in opposite directions in the two coils. Under these conditions the signals are received at the aeroplane only when the machine is in the immediate neighbourhood and approaching or receding from the station.

Gregory Breit, a physicist of the Bureau of Standards, has worked out mathematically the nature of the field from the two horizontal coils. It is proved that the maximum intensity of the signals occurs when the angle which the line joining the aeroplane with the landing-stage makes with the vertical is approximately 30°. The region of space within which the signal can be detected is nearly the space between two inverted coaxial cones with their axes vertical and their common apex at the transmitting station. The signals are inaudible directly overhead and rapidly die away when the aeroplane passes through the conical surface where the sound is a maximum. The lower the aeroplane also the louder the noise. The theoretical results have proved of great value in designing stations for emitting landing signals, and should be of considerable practical importance.

Industrial Research in India.

ONE of the bye-products of the new constitution legalised by the Government of India Act of 1919 was the transfer of certain "heads of business," previously administered by the bureaucratic regime, to the control of popularly elected Ministers in each province. The subjects so transferred included agriculture, forests, and the development of industries, with, therefore, the scientific and technical services attached to these departments. Realising that "decentralisation of authority and responsibility must necessarily tend to give rise to local variations in policy, apart altogether from those variations that follow local diversity in natural resources," Sir Thomas Holland, when designing the new Department of Industries and Labour in 1920, elaborated a system which would facilitate concerted action among the provinces while leaving them free to develop in any way that seemed to their respective legislatures best suited to their special needs. The new Ministers were in the first instance, provided with a monthly circular summarising the information, often of a semi-confidential nature, collected by the Intelligence Branch of the Munitions Board. Out of these circulars grew the agenda of half-yearly conferences, followed by a quarterly Journal and a series of Bulletins suitable for publication.

During 1921 four parts of the first volume of the Journal, amounting to 568 pages, well illustrated and fully indexed, were issued, and we have now received the first part of the new volume for 1922, together with twenty-three Bulletins on special subjects. The first part of the Journal published in 1921 was noticed last year in NATURE of April 7 (vol. 107, p. 179), and it is satisfactory to observe that the quality of the papers and the fundamental object of the publication have both been faithfully maintained. Some of the articles, like those by Dr E. R Watson and Mr. Mukerji on the alkaline "bad lands" of the United Provinces, by Mr. B M. Das on the tan-stuffs of the mangrove swamps on the Gangetic delta, by Mr. Appleyard on the manufacture of acetone and butyl alcohol, and by Messrs Gadre and Mukerji on rose otto, include the results of original research; but generally the articles and notes have an industrial rather than a scientific bias, avoiding the ground covered by those scientific and technical departments that have established journals of their own. Problems of factory welfare, which are beginning to assume embarrassing importance in India, occupy a conspicuous place among papers describing local ventures in glass manufacture, paper-making, tanning, pottery, oil-extraction, perfume distillation, wire-drawing, textile manufacture, and mineral enterprises.

The progress reports provided quarterly by the provincial Directors of Industries show the efforts being made to carry out the recommendations of the Industrial Commission which delivered its report towards the end of 1918. The reports generally give some justification for the claim made by Lord Chelmsford in his article in the *United Empire* for December last (vol. xii. p 778) that "never has effect been given more expeditiously" to a Commission's report. Differences of provincial outlook, however, still retard the adoption of the excellent scheme of chemical research drawn up by Prof. Thorpe's Committee in 1920, and without some such organisation to this end, by co-operation among the provinces, the industries of India must always retain their primitive "configuration" and remain distinctly behind, for example, those of a country like Japan.

Rainfall in Southern Italy and Tripoli.

PROF. FILIPPO EREDIA, of the Italian Meteorological Service, has recently contributed some further climatological studies to the many which he has already published. One of these (Nuovi Annali del Ministero per l'Agricoltura) deals with the seasonal conditions of rainfall in the province of Apulia and the relation of the quantity of precipitation to the number of days of incidence. The matter is important in connexion with the somewhat precarious water supply in that southern Italian province, which during the summer months is affected by the Saharan regimen of drought.

In another publication, on the rainfall of Tripoli ("L' Agricoltura Coloniale," Anno xv, No 8, 1921), Prof. Eredia shows that there is no foundation for the supposition that the rainfall of the region is steadily diminishing because the country shows signs of progressive desiccation. One might remark that progressive desiccation is considered to be the fact in many parts of Africa other than Tripoli, and that it has been explained by Schwarz and others as due, not to diminishing rainfall, but to a continental configuration which is slowly inducing baneful hydrological changes.

Two other papers on the climates of Gharian and Cussabat on the interior plateau of Tripoli (Bollettino di Informazioni, Nos. 3-4, 7-8, 1921) give an interesting glimpse of general climatic conditions based on a few years' records for meteorological observations since the Italian occupation. The mean annual temperature at Gharian, high up on the plateau and more than 2000 feet above sea-level, is about 65° F., ranging between 83° in July and 48° in January, and the mean daily range varies from 30° F. at midsummer to less than half that value at mid-winter. The absolute extremes of temperature recorded at this station were 121·1° F. in June and 32·1° F. in December, whilst extreme fluctuations of relative humidity characterise this dry region. The general rainfall of Tripoli is less than 20 inches a year, chiefly confined to winter. In this region we have another instance of the fact that occasional snowfalls at sea-level make a much closer approach to the tropics than is commonly supposed.

University and Educational Intelligence.

BANGOR.—Prof. D. Thoday of the University of Cape Town has been appointed to the chair of botany, in succession to Prof. R. W. Phillips, who retires after thirty-eight years' service.

BIRMINGHAM.—At the Degree Congregation held on July 1, in the great hall of the University at Edgbaston, the number of degrees conferred was the largest hitherto recorded for the University. Many of the new graduates are ex-service men, and the Principal (Mr. C. Grant Robertson) paid a tribute to the work of these men and their valuable help in creating afresh traditions of the University after the war: "They have given us invaluable service in that necessary work. They brought to the University a breadth and a variety of experience, a maturity of judgment, and an energy and enthusiasm which those who know the University from the inside recognise has been invaluable, and which will leave a permanent imprint on our University life and a permanent addition to our University traditions." The institution by the Government of grants to ex-service men was a unique educational experiment and, judging by the experience of Birmingham University, it had proved an unqualified success.

The following degrees were conferred: *Doctor of Science*: Mr. R. H. Whitehouse; *Doctor of Medicine*: Mr. O. J. Kauffmann, Mr. J. Robertson, and Mr. J. W. Russell; *Philosophiæ Doctor*: Mr. F. Adcock, Mr. C. B. Childs, Mr. V. A. Collins, Mr. E. A. F. Reeve, Mr. J. D. M. Smith, Mr. R. E. Stradling, Mr. F. H. Wells; *Master of Surgery*. Mr. L. P. Gamgee. For the degree of Master of Science, 45 candidates were presented; for the degree of B.Sc. with Honours, there were 74 candidates, and for the ordinary B.Sc. degree, 157.

The Vice-Chancellor, Sir Gilbert Barling, announced that a war memorial was to be erected on the east wall of the entrance hall, in the form of three marble panels bearing the names of the members of the University of all ranks who fell in the war. It is expected that the memorial will be unveiled in October next.

Mr. C. G. Payton has been appointed demonstrator in anatomy.

The Ingleby Lecturer for 1924 will be Mr. A. W. Nuthall.

CAMBRIDGE.—In connexion with the meeting of the Royal Agricultural Society (the "Royal Show"), honorary degrees are being conferred on H.R.H. The Duke of York, the Honourable W. H. Taft, Mr. C. R. W. Adeane, Sir G. Greenall, Sir Daniel Hall, Mr. E. S. Beaven, Mr. A. E. Humphries, Mr. E. Mathews, and Mr. G. P. Hawkins. Mr. L. C. G. Clarke, Trinity College, has been appointed curator of the Museum of Archæology and of Ethnology.

LONDON.—Prof. H. S. Birkett (Dean of the Faculty of Medicine, McGill University) will deliver the Semon Lecture at the Royal Society of Medicine, 1 Wimpole Street, W.1, on Wednesday, July 12, at 5 o'clock. The subject will be "The development of Trans-Atlantic Rhino-laryngology." Admission will be free and no tickets will be required.

OXFORD.—At the Encaenia, held on June 28, the honorary degree of D.Sc. was conferred on Prof. J. Perrin of Paris and Prof. F. Gowland Hopkins of Cambridge. In introducing Prof. Perrin, the Public Orator (Dr. Godley) referred particularly to his experimental researches in the character and constitution of the atom, and to his determination of the velocity of the component electrons. His scientific investigations had been used in the service of his country, and had contributed largely to its victory in the war. Of the work in biochemistry of Prof. Gowland Hopkins, the Orator found it difficult to speak "in hac patria sermonis egestate." He was able, however, to pay tribute in general terms to Prof. Hopkins's abstruse researches into the nutrition and metabolism of living bodies. His discovery of the importance of vitamins was not only of high scientific value, but had also a practical bearing of the greatest interest in the study of disease. Prof. Perrin was greeted by the Vice-Chancellor (Dr. L. R. Farnell, Rector of Exeter College) as "Vir doctissime; maxime physicae scientiae auctor", and Prof. Hopkins as "Vir eruditissime; chemiae explorator insignis; Universitatis Cantabrigiensis decus."

SHEFFIELD.—Honorary degrees have been conferred on Sir Charles Parsons for his work on the turbine engine, and on Mr. T. W. Hall for researches in palæography and archæology.

DR. R. H. CHITTENDEN, the well-known authority on dietetics, is retiring from the post of director of the Sheffield Scientific School, Yale University, which he has held since 1898. He is to be succeeded by Dr. C. H. Warren, now professor of mineralogy at the Massachusetts Institute of Technology and a former assistant at the Sheffield Scientific School, of which he is himself a graduate.

Calendar of Industrial Pioneers.

July 1, 1860. Charles Goodyear died.—The father of the American rubber industry, Goodyear was born at New Haven, Connecticut, on December 12, 1800, his father, Amasa Goodyear, being known as an inventor of agricultural implements and a manufacturer of hardware. The failure of his father's business about 1830 led Goodyear to study the problem of "curing" rubber, which at that time became soft and sticky in summer and brittle in winter. Always in debt, sometimes in prison, and often regarded as a crank, Goodyear persevered until, in 1839, he accidentally discovered that by partly melting rubber and sulphur the rubber could be given varying degrees of hardness and elasticity. His first patent was taken out in 1844, and though he reaped no fortune he continued to improve the manufacture and extend the use of rubber until his death.

July 2, 1798. John Fitch died.—One of the pioneers of steam navigation, Fitch was the son of a farmer of Windsor, Connecticut, and was born on January 21, 1743. After a few sea voyages he engaged in clockmaking and brassfounding, and as a gunsmith to the American troops during the War of Independence made a considerable fortune. His project of driving boats by steam was launched in 1785, and the following year he formed a company and secured exclusive rights in New Jersey and other States. A boat built by him and placed upon the Delaware in 1790 was the first steam vessel to convey passengers for hire. The undertaking, however, proved financially unsuccessful, and three years later Fitch met with no more success in France. Reaping nothing but disappointment and poverty, his mind gave way, and he died by his own hand at Bardstown, Kentucky.

July 5, 1826. Joseph Louis Proust died.—Trained as a chemist by his father, Proust made one of the earliest balloon ascents, was for some years employed by the King of Spain, and discovered a process of making grape sugar. He was also known for the enunciation of the law of constant proportion and for his controversies with Berthollet.

July 5, 1883. Robert Spence died.—Beginning life as a grocer, Spence afterwards found employment in the Dundee Gas-works and became the proprietor of chemical works in London, Manchester, and elsewhere. In 1845 he discovered the process of making alum from the refuse shale of collieries and the waste ammoniacal liquor of gas-works, and became the chief alum manufacturer in the world. He also took out many patents in connexion with industrial chemistry and metallurgy.

July 7, 1850. Timothy Hackworth died. Born at Wylam, near Newcastle, in 1786, Hackworth became a foreman smith and assisted in some of the pioneering work on the locomotive. Appointed in 1825 resident engineer and manager of the Stockton and Darlington Railway, he built the *Royal George*, which definitely asserted the superiority of steam over horse traction, and in 1829 produced the *Sans Pareil*, a worthy competitor with Stephenson's *Rocket*, at Rainhill.

July 7, 1896. Sir John Pender died.—A successful merchant in textile fabrics in Manchester and Glasgow, Pender was an enthusiastic supporter of submarine telegraphy, and was one of the 345 subscribers who each risked a thousand pounds in the Atlantic Cable of 1857. He personally guaranteed 250,000*l.* to the Telegraph Construction and Maintenance Company in 1865, and at his death was the head of various concerns owning 73,640 nautical miles of submarine cable and having a capital of fifteen millions.

July 10, 1867. Thomas Richardson died.—Trained as a chemist under Thomas Thomson, Liebig, and Pelouze, Richardson became a chemical manufacturer at Newcastle, introduced improvements in the production of lead, and began the manufacture of superphosphates. He lectured on chemistry in Durham University, published information about the industries of the north, and with Ronalds translated Knapp's "Technological Chemistry."

July 10, 1874. John Grantham died.—The author of a standard work on iron shipbuilding, Grantham designed many sailing-ships and steamships, patented a screw-propeller, and devised a method of sheathing iron ships with copper. He was also joint engineer with his brother to the northern railway of Buenos Aires and planned the first tramway in Copenhagen. He was one of the founders of the Institution of Naval Architects.

July 12, 1892. Cyrus West Field died.—Born in Stockbridge, Massachusetts, November 30, 1819, Field built up a large paper-manufacturing business, and then in 1854 turned his attention to submarine telegraphy, ultimately becoming the chief promoter of the Atlantic Telegraph. It has been said, "Let who will claim the merit of having said the Atlantic cable was possible, to Mr. Field is due the inalienable credit of having made it possible, and of giving to an abortive conception all the attributes of healthy existence." His share in the great enterprise was recognised by the award to him by Congress of a gold medal, and he received the thanks of the American nation.

July 12, 1910. Charles Stewart Rolls died.—A pioneer of the motor-car in England, an expert aeronaut, and the first English victim of aviation, Rolls was the son of Baron Llangattock and was born August 28, 1877. Educated at Eton and Trinity College, Cambridge, he studied practical engineering, and in 1895 purchased his first motor car. Nine years later he founded the well-known firm of Rolls-Royce, Ltd. To study Wilbur Wright's experiments he visited France in 1908, acquired a Wright aeroplane, and became an expert flyer. In June 1910 he crossed and recrossed the Channel without stopping. His death was due to an accident to the machine he was flying at Bournemouth.

July 14, 1806. Emiland Marie Gauthey died.—A student at the École des Ponts et Chaussees, under the celebrated Perronet, Gauthey rose to eminence in the French service, and was especially known for the construction of the Canal du Centre in Burgundy. His "Traité complet sur la construction des ponts et des canaux navigables" was published in 1809 by his nephew Navier.

July 14, 1808. John Wilkinson died.—The father of the iron trade in Staffordshire, Wilkinson was born in 1728, and learned the art of smelting from his father. In 1748 he built a blast furnace at Bilston, Staffordshire, using coke for fuel, and afterwards had works at Bersham and Broseley. He introduced the boring of cannon, in 1787 he constructed an iron barge, and he also patented a method of making lead pipes.

July 14, 1887. Alfred Krupp died.—The son of Friedrich Krupp (1787–1826), who opened a small iron forge at Essen in 1810, Alfred Krupp was born April 26, 1812, and at an early age succeeded to the management of the business which, in his hands, became of world-wide importance. He made the first steel gun, established the first Bessemer works in Germany, and manufactured large quantities of ordnance and railway material. The works at Essen cover an area of about five square miles, while the firm, in its various establishments, employs some 80,000 men.

E. C. S.

Societies and Academies.

LONDON.

Royal Society, June 22.—Sir Charles Sherrington, president, in the chair.—G. I. **Taylor**: The motion of a sphere in a rotating liquid. There are an *infinite number of solutions* to the equations of motion of a rotating fluid, when a sphere is moved uniformly along the axis of rotation, which satisfy the boundary conditions and the conditions at infinity. They are characterised by spherical rotational waves which accompany the sphere. The radius of the sphere may be reduced to zero without reducing the disturbance in the fluid to zero. The equations then represent a motion which is finite and continuous at the centre, and consists of a central core of fluid which rotates more slowly than the surrounding fluid and travels along the axis with a constant speed.—T. R. **Merton** and D. N. **Harrison**: On errors arising in the measurement of unsymmetrical spectrum lines. The instrumental displacements occurring while spectra are being photographed can be rendered innocuous, for wave-length determinations, only when the spectrum lines are symmetrical. With uniform displacement of a line during exposure, the maximum on the photographic plate occurs where the intensity distribution curves at the beginning and end of the exposure intersect. When the ratio of the widths on either side of the maximum of the curve remains constant for all values of the intensity, the displacement of the maximum is simply related to the "index of asymmetry" of the line.—E. F. **Armstrong** and T. P. **Hilditch**: A study of catalytic actions at solid surfaces. Pt VIII. The action of sodium carbonate in promoting the hydrogenation of phenol. Small amounts of mild alkali, especially anhydrous sodium carbonate, stimulate the hydrogenation of liquid phenol in presence of nickel. The amount of sodium carbonate has a specific influence, the optimum being about 25 per cent. of the weight of metallic nickel present. The hydrogen-absorption time curves for phenol in presence of nickel and in absence of sodium carbonate are of logarithmic type, with the optimum concentration of carbonate they are approximately linear. The sodium carbonate suppresses a retarding or poisoning influence, leaving the nickel free to exercise its normal function. The toxic agent appears to be some stable association between the nickel and phenol, or a product from the latter, possibly nickel phenate. Pt. IX. The action of copper in promoting the activity of nickel catalyst. Copper-nickel catalysts prepared at 180° C. are not so active as the plain nickel catalyst, distributed to give the maximum surface area, reduced at a higher temperature. For maximum activity, the proportions of the mixed carbonates must be such that nickel α-cupri-carbonate is present in the precipitate. The preparations yielding active catalysts respond to Pickering's tests for complex cupri-carbonates. The production of a little reduced nickel at this low temperature is conditioned, perhaps, by the heat liberated in the reduction of the copper.—E. A. **Milne**: Radiative equilibrium: the relation between the spectral energy curve of a star and the law of darkening of the disc towards the limb, with special reference to the effects of scattering and the solar spectrum. For stars in radiative equilibrium the darkening of the disc towards the limb in wave-length λ depends only on the product λT, T being the effective temperature. The ratio of the intensity at the limb to that at the centre increases as λT increases, but never exceeds 0·8; it approaches zero for small values of λT. For stars not in radiative equilibrium the coefficient of darkening in the integrated radiation must lie between $\frac{3}{5}$ and $\frac{1}{2}$, and the temperature distribution near the surface can be deduced. Selective absorption in the continuous spectrum alters the law of darkening. A scattering atmosphere round a star should make the coefficients of darkening in all wave-lengths tend to the same value, about $\frac{2}{3}$. The observed darkening of the continuous solar spectrum differs very little from the theoretical darkening for radiative equilibrium; it is not possible to correlate the spectrum with the darkening, either on the hypothesis of selective absorption or on that of a scattering atmosphere. Probably there is no scattering atmosphere of appreciable optical thickness round the sun, and the bulk of the emergent radiation is not scattered light.—C. N. **Hinshelwood**: On the structure and chemical activity of copper films and the colour changes accompanying their oxidation. The gradual activation of a copper surface in a series of oxidations and reductions has been studied at pressures of a few millimetres. A limiting state appears to be reached in which the copper film has an open structure consisting of granules of radius a small fraction of 1μ. During oxidation, brilliant diffraction colours are observed, depending upon the composition of the separate granules. The mechanism by which the film becomes granular is discussed.—R. C. **Ray**. Heat of crystallisation of quartz. The difference between the heats of solution of quartz and silica glass in aqueous hydrofluoric acid, and the specific heats of aqueous hydrofluoric acid represents the heat of crystallisation of quartz at the ordinary temperature, and is 0·95 kilogram calories. Grinding converts the crystalline material partly into the vitreous state. Near the melting-point the heat of crystallisation is probably nearly equal to that at air temperature.—C. G. **Schoneboom**: Diffusion and intertraction. With fluid-mixing, in addition to diffusion, another specific operating factor called "Intertraction" has been found experimentally. Clerk Maxwell, in discussing interfacial tension, concluded that an interpenetrating movement of this kind was *a priori* to be expected. The phenomenon has been described by Sir Almroth Wright in the special case of the admixture of serum and salt solutions, but it can be obtained with practically any substance in any solvent.

Geological Society, June 14.—Dr. G. T. Prior, vice-president, in the chair.—P. G. H. **Boswell**: The petrography of the Cretaceous and Tertiary outliers of the west of England. The outliers of Upper Greensand on the Haldon Hills, the Eocene (?) of Marazion, Buckland Brewer, and the Haldon Hills, and the Oligocene of Bovey Tracey and Petrockstow are discussed. Andalusite, topaz, and tourmaline are the typical minerals. Minerals foreign to the West Country, such as kyanite and staurolite, are also abundant in the Cretaceous and Pliocene. The mineralogical constitution yields evidence of a progressive restriction of drainage-area, commencing with the marine and glauconitic Greensand and continuing through the fluviatile (?) Eocene to the lacustrine Bovey deposits, and of a reversion to marine conditons with a polygenetic mineral assemblage in the Pliocene.—W. N. **Benson** and S. **Smith**: On some rugose corals from the Burindi Series (Lower Carboniferous) of New South Wales. The corals were obtained from the western foothills of the New England Plateau, in the north-eastern portion of the

ntry. The region consists mainly of Upper leozoic rocks, Devonian to Permian. The Burindi les is made up of olive-green mudstones and tuffs, h occasional lenticular masses of oolitic and oidal limestone. From these intercalations the ils, which are related to Cyathophyllum and lostrotion, were obtained. Both forms have ormally large columellæ. The species of Lithostrotion have small peculiarities of structure, which inguish them as a group from British species.

EDINBURGH.

Royal Society, June 5.—Prof. F. O. Bower, president, in the chair.—A. N. **Whitehead**: The relatedness of Nature. Hume disposed of the theory of the relatedness of Nature as it existed in the current philosophy of his time. We can discern in Nature ground of uniformity of which the more far-reaching example is the uniformity of space-time, and the more limited example is what is usually known under the title of "The Uniformity of Nature." Our arguments must be based upon considerations of the utmost generality, untouched by the peculiar features of any particular natural science. Every entity is an abstraction from the concrete, which in its fullest sense means totality. The important point of that doctrine is that any factor of Nature, by virtue of its status as a limitation within totality, naturally refers to factors of totality other than itself. Equality of limitude is the significance of factors. The uniform significance of events becomes the uniform spatio-temporal structure. In that respect it is necessary to dissent from Einstein, who assumes for that structure casual heterogeneity arising from contingent relations. The structure is uniform because of the necessity for knowledge that there should be a system of uniform relatedness, in terms of which the contingent relations of natural factors can be expressed. Otherwise we can know nothing until we know everything. It is evident that a scientific object such as an electron must qualify future events, for otherwise the future contingency is unaffected by it. In that, a scientific object differs decisively from a sense-object. A sense-object qualifies events in the present. Thus, the seemingly contingent play of the senses is controlled by the conditions brought about by its dependence upon the qualification of events introduced by the scientific object.

SHEFFIELD.

Society of Glass Technology, June 21.—Prof. W. E. S. Turner in the chair.—Y. **Amenomiya**: The devitrification caused upon the surface of sheet glass by heat. Heat causes devitrification, or crystallisation of window glass. This alteration takes place between 700° and 800° C.—K. **Kamita**: The influence of alumina in preventing the devitrification of sheet glass during the drawing process. As the amount of alumina in the glass increased in the samples used, so the temperature at which devitrification occurred was raised; 5 per cent. of alumina caused a rise of approximately 100° C. in the temperature at which devitrification commences.—L. E. **Norton**: The apparent swelling of sand on the addition of water. With three typical sands the addition of water caused difficulty in packing equivalent to swelling which might be 12-15 per cent. of the total dry sand. The maximum effect occurred when 5-6 per cent. of water was mixed with the sand.—W. E. S. **Turner**: The mixing of batch. Taking three works samples from batch mixed by hand, the maximum variations were 44-77 per cent. sand and 4·8-8·3 per cent. lime, while a similar batch mixed by different machines showed variations of 69-73 per cent. sand and 4·2-6·6 per cent. lime. Machine mixing, by giving a much more regular batch, assisted the melting, and materially reduced the time necessary for the production of good glass.

PARIS.

Academy of Sciences, June 12.—M. Emile Bertin in the chair.—Henry le **Chatelier**: The geometric representation of saline equilibria. Remarks on a question of priority raised by Prof. Jaenecke.—Charles **Depéret**: An attempt at the general chronological co-ordination of quaternary time.—Maurice **Leblanc**: The use of air as a cooling agent. A theoretical and practical comparison of the use of liquid ammonia and compressed air as cooling agents, with a study of the best conditions for using the latter.—A. **Rateau**: General theory of the turbo-compressor for aviation motors. The compressor is worked by the exhaust gases from the engine and delivers the air to the cylinder at about double the atmospheric pressure. It is especially designed for use at high altitudes.—M. **Riquier**: Singular integral figures of passive systems of the first order involving only a single unknown function.—Jules **Andrade**: Three classes of non-maintained isochronal vibrations and three types of timepieces. New instruments for the experimental study of viscosities.—G. **Friedel** and L. **Royer**: Liquids with Grandjean's equidistant planes.—Torsten **Carleman**: Asymptotic series.—G. **Valiron**: Hermite's method of approximation.—Georges **Rémoundos**: The general problem of the thrust of earth.—M. **Sudria**: The elastic deformation of an isotropic body.—E. **Merlin**: The calculation of heliographic co-ordinates.—M. **Dufour**: The refraction of a luminous pencil in the general case.—A. **Andant**: The variations of critical opalescence with the filling of the tubes and the nature of the liquids studied. The effects of the variation of critical opalescence with the temperature and with the wave-length of the incident light have been described in an earlier paper. The ratio of liquid to vapour in the tube (D) also affects the phenomenon, and the temperature of reappearance of the meniscus is now shown to be a parabolic function of D. A study of the acetates of methyl, ethyl, butyl, and isobutyl shows that the opalescence increases in intensity and extent, passing from the first to the fourth of these acetates.—A. **Dauvillier**: The exact measurement of the energy levels of the barium atom and the appearance of the L ionisation spectrum.—M. de **Broglie** and A. **Dauvillier**: A new absorption phenomenon observed in the field of the X-rays.—A. **Damiens**: The crystallisation of amorphous tellurium. According to Berthelot and Fabre, the crystallisation of tellurium is an endothermic phenomenon, thus forming an exception to the general rule. A repetition of the experiments of Berthelot and Fabre has shown that the reaction used by them (bromination of tellurium) is not complete in the case of crystallised tellurium, and by substituting bromine in hydrochloric acid for bromine and water it is proved that the change from amorphous to crystallised tellurium is accompanied by an evolution of heat. Tellurium thus falls into line with other amorphous substances.—R. **Locquin** and Sung **Wouseng**: The preparation of the dialkylvinyl-carbinols. A general method for preparing the unsaturated alcohols of the type RR′-C(OH)-C≡CH has been given in an earlier communication. By a suitable catalyst (reduced nickel) these can be reduced by hydrogen to the corresponding tertiary ethylene alcohols

$RR'-C(OH)-CH=CH_2$; the preparation and properties of three of these are described.—E. E. **Blaise** and Mlle. **Montagne**: The action of thionyl chloride on the α-acid alcohols. With lactic and α-oxyisobutyric acids, thionyl chloride forms anhydro-compounds of a new type.—MM. **Pastureau** and Henri **Bernard**: The chlorhydrin of mesityl oxide and its transformation into the chlorhydrin of tetramethyl glycerol.—Edmond **Gain**: The comparative resistance to heat of the growing points of the embryo of the sunflower. If the seeds have been submitted before germination to temperatures just below those capable of destroying life (110° to 155° C.) the various points capable of growth are shown to be unequally sensitive, that of the root being most easily destroyed.—Maurice **Lenoir**: Somatic kinesis in the aerial stem of *Equisetum arvense*. From the facts described it would appear that the fundamental substance of the chromosome is the nucleolin, the chromatin is derived from it.—Mlle. Marguerite **Larbaud**: The anatomy of flowers of the same species at different altitudes. A detailed comparison of plants of *Silene inflata* grown at about sea-level and at 2000 metres altitude.—Gabriel **Bidou**: An artificial musculometer.—Clément **Vaney** and Jean **Pelosse**: Origin of the natural coloration of the silk of *Bombyx mori*. The colouring matter from the silk and that derived from the leaves of the mulberry tree give identical absorption spectra in alcoholic solution. This confirms the view of Conte and Levrat that the silk cocoons derive their colour from the pigments of the leaf serving as food for the silkworms.—M. **Aron**: The development of the primary sexual characters in *Triton cristatus*. Hypothesis on its determinism.—P. **Bouin**: Dipyrenid of the sperm in certain double spermatogeneses is obtained by a heterotypical mitosis produced in the course of development.—A. **Pézard**: The idea of the "*seuil différentiel*" and humoral interpretation of the gynandromorphism of the bipartite birds. In these birds the plumage is divided into two parts following the plane of symmetry of the body, one half having a male appearance, the other female. The reproductive organs show corresponding peculiarities.—A. **Desgrez**, H. **Bierry**, and F. **Rathery**: A balanced food regime and diabetic acidosis.—Pierre **Goy**: Microbial physiology and the accessory growth factor. It appears to be impossible to determine Vitamine B by studying its action on the growth of yeast.—Charles **Lebailly**: The duration of the contagious period in aphthous fever.

CAPE TOWN.

Royal Society of South Africa, May 17.—Dr. J. D. F. Gilchrist, president, in the chair.—J. R. **Sutton**: The control of evaporation by the temperature of the air. The rate of evaporation from the surface of the water in a metal gauge sheltered by a louvred screen increases as the air temperature rises above that of the water. In the space just above the water the relative humidity is much higher than, while the temperature there is about the same as, that of the free air. The results illustrate the general law that water vapour diffuses along the relative humidity gradient.—Sir Thomas **Muir**: Note on a determinant with factors like those of the difference-product.—J. **Moir**: Colour and chemical constitution, Pt. XVII. The azo dyes and other monocyclic colours. By spectrophotographic means, and replacing N by CH and eliminating N or CH, the azo dyes are calculable from oxy- and amino-benzaldehyde, previously calculated in Pt. XIII. Quinone and its imines all have six bands, one pair for neutral, another pair for acid, and a third pair for alkaline solution.

By Chih Ping. Pp. 555-616. Memoir 50: The Relative Growth-promoting Value of the Protein of Coconut Oil Meal, and of Combinations of it with Protein from various other Feeding Stuffs. By L. A. Maynard and F. M. Fronda. Pp. 617-633. Memoir 51: The Hog Louse, Hæmatopinus Suis Linné: its Biology, Anatomy, and Histology. By Laura Florence. Pp. 635-743. Memoir 52: Studies in Pollen, with Special Reference to Longevity. By H. E. Knowlton. Pp. 745-793. (Ithaca, N.Y.: Cornell University.)

Diary of Societies.

FRIDAY, JULY 7.

ROYAL SOCIETY OF MEDICINE, at 5.—Dr. A. F. Hess: The Effect of Light in the Prevention and Cure of Rickets.

TUESDAY, JULY 11.

INTERNATIONAL NEO-MALTHUSIAN AND BIRTH CONTROL CONFERENCE (at Kingsway Hall, Kingsway, W.C.2), at 10.—Dr. C. V. Drysdale: Presidential Address.—At 2.30.—Dr. Jane L. Hawthorne: Birth Control as it affects the Poor.—E. Cecil: C3 Motherhood.—Mrs. B. I. Drysdale: The Individual and the State.—Miss F. W. Stella Browne: The Feminine Aspect of Birth Control.—Dr. Frances M. Huxley: Birth Control from the Point of View of a Woman Gynæcologist.

SOCIETY FOR THE STUDY OF INEBRIETY (at 11 Chandos Street, W.1), at 4.—C. J. Bond: The Influence of Hospitals on Temperance Reform (Presidential Address).

WEDNESDAY, JULY 12.

INTERNATIONAL NEO-MALTHUSIAN AND BIRTH CONTROL CONFERENCE (at Kingsway Hall, Kingsway, W.C.2), at 10.—Dr. C. V. Drysdale: The Criterion of Overpopulation.—Dr. B. Dunlop: A Malthusian View of Death Rates and of the Average Duration of Life.—Prof. K. Wicksell: The Crux of Malthusianism.—Prof. R. Michels: Emigration and the Birth Rate.—Baron Keikichi Ishimoto: The Population Problem in Japan.—A. M. Carr Saunders: The Historical Aspect of Birth Control.—Prof. E. Punke: Birth Control and Organised Labour.—At 2.30.—Moral and Religious Section.

FELLOWSHIP OF MEDICINE (at Royal Society of Medicine), at 5.—Prof. A. H. Todd: Surgery in Rheumatoid Arthritis.

THURSDAY, JULY 13.

INTERNATIONAL NEO-MALTHUSIAN AND BIRTH CONTROL CONFERENCE (at Kingsway Hall, Kingsway, W.C.2), at 10.—Prof. E. W. MacBride: Birth Control and Biological Law.—M. Pollock: The Problem of the Unfit.—Prof. W. F. Willcox: Economic Competition between American Races, Negro and White.—Miss Mary Winsor: The Cost to the State of the Socially Handicapped and the Socially Unfit.—Prof. P. W. Whiting: Relation of Recent Advances in Genetics to the British Control Programme.—Dr. H. Hart: Differential Fertility in Iowa.—Prof. K. Dunlap: Psychological Factors in Birth Control.—At 2.—H. Cox: International Aspects of Birth Control.—Dr. A. Nystrom: Overpopulation of the Earth and its Dangers.—J. O. P. Bland: The Far Eastern Population Question.—Mrs. Anne Kennedy: Birth Control in the United States.—Prof. Isoo Abe: The Birth Control Movement in Japan.—Dr. F. Goldstein: Birth Control the Saving of Civilisation.

FRIDAY, JULY 14.

INTERNATIONAL NEO-MALTHUSIAN AND BIRTH CONTROL CONFERENCE (at Kingsway Hall, Kingsway, W.C.2), at 10.—Dr. C. K. Millard: Birth Control and the Fertility Question.—Dr. A. Nystrom: The Necessity for abolishing Laws against Preventive Measures.—Dr. H. Rohleder: Neo-Malthusianism from the Medical Standpoint.—Dr. D. R. Hooker: Effect of X-rays upon Reproduction in the Rat.

PUBLIC LECTURE.

WEDNESDAY, JULY 12.

ROYAL SOCIETY OF MEDICINE, at 5.—Prof. H. S. Birkett: The Development of Trans-Atlantic Rhino-Laryngology (Semon Lecture).

SATURDAY, JULY 15, 1922.

Telephone Number: GERRARD 8830.

Specialisation in Universities.

It is not the function of a university to make provision for teaching all the sciences; still less is it the function to confine its work to one narrow branch of specialised study. In one case, apart from the difficulties inherent in such an aggregation, the financial cost would be prohibitive; in the other, a limitation of such a nature would be wholly alien to the modern conception of a university, where, in place of the breadth and proportion of view which comes from the attrition of minds engaged in diverse studies and pursuits, would be found the narrowness and exclusiveness of intellectual segregation. We may therefore dismiss one extreme as impracticable and the other as undesirable.

The universities of to-day have many subjects of study in common. Happily the freedom to develop according to their own individualities, which has hitherto been their lot, has resulted in certain characteristic differences. It is devoutly to be hoped they may not lose these distinctions. The studies common to all universities form a broad humanistic and scientific foundation which is the basis of the intellectual life of the university. Superimposed upon this are the more highly specialised studies, which may in some cases cover a very narrow field, but not seldom form a department in the university linked up in innumerable ways with one or more branches of industrial or commercial life outside. This development has been gradual and, in general, continuous, and it is due to a variety of causes of which probably the two most effective may be defined as historical and regional or environmental. As matters now stand, some studies have already been specialised in certain of the universities and, until quite recently, largely by a process of natural development. To overlook or to underestimate the importance and bearing of this fact would be a mistake.

If the universities were self-supporting or mainly so, it is unlikely that the present system, which on the whole has worked well, would be challenged—it may yet prove to be the best in any circumstances—but since they are not self-supporting, and since they are coming to rely more and more upon assistance from State funds and local rates, they need not be surprised if a time comes when a critical eye is turned upon their activities. Such a time is with us now. The cry for economy, the reduction in the Government grant, the threat of lean years ahead, apart from other considerations, have brought to the forefront the question of the overlapping of university studies, and the possibility of better co-ordination and co-operation of the universities in the future, especially with regard to

the ever-increasing [illegible] technology and applied science.

With regard to the question of overlapping it should be remarked that, at the recent conference in London of the Universities of Great Britain and Ireland, no statement was more generally applauded than that of Prof. Ripper, of Sheffield, who reminded the conference and the public that at present there was no unnecessary overlapping in university studies. Overlapping there may be, but whether this is unnecessary and wasteful is quite another question and one which cannot be answered by mere statistics. This is where co-operation would be most useful both now and in the future. The Minister of Education was on sound lines when, in addressing the conference, he advised the universities to take counsel with one another and husband their resources. Possible wastefulness due to overlapping ought not to be disregarded at any time and most certainly not at a time of financial stringency.

If, for example, each university were to attempt to cover all the main branches of technology, though perhaps the demand for university-trained technologists in a particular field did not reach a score annually, then disappointment and ineffective work must be the result. Obviously where the demand for trained technologists in a particular subject is limited to a comparatively small number, there is distinctly a case for specialising the study in one university. How far universities would attempt to compete with one another in such cases it is difficult to say. But it is worth recalling that, at the conference to which we have already alluded, Mr. Fisher directed attention to the public-spirited action of the University of Leeds a few years ago when glass technology was proposed as a subject for university research. It appears that either Leeds or Sheffield might have been the seat of the new department, but after a conference Leeds agreed to the new work being centred in Sheffield on the ground that the Yorkshire glass industry as a whole was more accessible from there than from Leeds. The method of procedure by conference should be noted.

Cases such as this are obviously cases for specialisation and are perhaps not difficult to settle. It would seem that the limited demand points to concentration and the "regional pull" to the particular university. On the other hand such highly specialised subjects as technical optics, oceanography, hydro-electrics cannot be said to have so localised a regional pull, nor Chinese, Assyriology, and a host of others. Again, departments of study connected with agriculture, forestry, leather industries, dyeing, textile industries, metallurgy, fuel and coal gas industries are already established in one [illegible] in these departments, especially if [illegible] considerable expense, obviously there would [illegible] occasion for co-operation among the various universities interested with the view of suitable distribution of the work.

So far we have been considering the subject of specialisation in universities from the point of view either of the more highly specialised studies or of technology or applied science generally, and have indicated our opinion that in these fields there will be ample scope and real necessity for co-ordination and co-operation. But there is another aspect of the problem which is apt to be overlooked or even in danger of being confused with the one just considered. It has relation to those basic humanistic and scientific studies which are the foundations of the intellectual life of the universities. Among them are included such subjects as the classics, English, history on one side, and mathematics, physics, chemistry on the other. They are found in all our universities, and rightly so, and so long as the university is conceived as "a spirit, a principle of life and energy, an influence . . . caring for the spirit and mind of man, regardless of considerations of utility," so long will they remain there. While, therefore, it is not disputed that the more fundamental of them should be taught in every university, it may be urged in the interests of a specious economy that the prosecution of research in them should be specialised in certain universities. This, we believe, would be a most dangerous principle to adopt, and would be quite contrary to the true spirit of the university. The effect upon the teaching would be little short of disastrous. In its Report of 1921 the University Grants Committee is clear that "sufficient leisure to pursue research is as essential as adequate remuneration," and that "no institution claiming university rank can rest content while it fails to provide opportunities for the advancement of knowledge, nor can junior teachers hope to rise in their profession or indeed carry out their teaching duties efficiently unless such opportunities are open to them." This extract amply confirms the general opinion expressed at the second Congress of the Universities of the Empire, 1921, regarding the great importance and value of research to a university teacher. Without research behind him a university teacher fails in the freshness, mastery, and inspiration required of a good teacher of university students. Whenever such fundamental studies are found in a university some opportunities for research in them should be provided. This may mean overlapping, but it is not overlapping involving wastefulness.

[illegible] included in [illegible] versity for regional or local reasons. If it is argued that the undergraduates might travel to another university for the necessary instruction, it may be replied that in most cases it would be inconvenient and expensive and not seldom impossible. Assuming that the subject is taught in the university, the arguments adduced above show conclusively that opportunities for research are indispensable. A possible alternative would be to bring a teacher from another university to give a course of instruction in it. This is a plan which, though it has been adopted with good results in some universities, is not always possible or desirable. One can picture a case, in economics for example, where investigations into local conditions are absolutely necessary for the proper development of the teaching of the subject, and no substitute can adequately replace it.

While we are sensible of the need for economy and the avoidance of all unnecessary overlapping in our universities, we are also sensible of the wonderful developments which have taken place in higher and specialised studies in the few decades during which the modern universities have come into being and attained some degree of maturity. It may well be said that "not since the monastic period of the twelfth century, or the scholastic revolution of the sixteenth, has England known an educational movement so rich in romance, in courage, in devotion, and in promise." This extraordinary expansion and development, which has changed the whole face of education in England, is one of self-development untrammelled by vexatious restrictions. The modern university has developed under the wing of the State; it can no more dispense with Government assistance than it can with its students or staff. But if it is to fulfil its rightful destiny it must retain its freedom to develop from within. By all means let there be co-operation and co-ordination among the various universities, just as there are within the university itself. But if, unhappily, any attempt to lop or prune activities, hitherto self-determined, were to succeed, the measure of its success would be the measure of the nation's loss.

More Light on the Bantu Languages.

A Comparative Study of the Bantu and Semi-Bantu Languages. By Sir Harry H. Johnston. Vol. 2. Pp. xii + 544. (Oxford: Clarendon Press, 1922.) 3*l.* 3*s.*

AFTER numerous and vexatious delays, the second volume of this monumental work has at last seen the light. It contains "an analysis and com[illegible] and [illegible] a comparative examination of [illegible] the Bantu and Semi-Bantu languages, together with the conclusions to be derived from this evidence." In accordance with this plan we have, first, a review of the various groups of Bantu and Semi-Bantu languages, following the arrangement adopted in the first volume. (An alphabetical index of languages, by the bye, would greatly facilitate research, though the student is helped to a considerable extent by the table on pp. 2-13. In vol. 1, those not gifted with a remarkable memory for numbers had to turn over the pages till they found the particular language required.)

The classification adopted is open to some objections in detail—as was almost inevitable in the circumstances: but one had hoped to see some outstanding inaccuracies corrected in vol. 2, *e.g.* the treatment of the two distinct languages Lala and Lamba as one and the same. This, of course, is due to Madan, the only authority accessible when the vocabularies were prepared; but other sources of information have since become available. Again, there is some confusion (vol. 1, p. 281, vol. 2, p. 79) as to the languages entered under 70: Chopi, to adopt the ordinary orthography, is a distinct language from Tswa, and also, we believe, from Lenge, which, again, is not the same as Hlengwe. (See *e.g.* Junod's map in the "Grammaire Ronga." Sir Harry Johnston dissents from this writer's view, but it is supported by good recent authority.)

The paragraphs dealing with "Group T: the Zulu-Kafir languages" contain several points calling for discussion. It is surely by an oversight that the palatal click (*qc*, *q*) is said to be "confined mainly to Zulu and Sesuto." It does not occur in Zulu, and only doubtfully in Xosa. (Bleek: "*Vide* Boyce-Davis, p. 4, where the *qc* is probably intended to indicate this sound.") The fact that it is found in Sesuto is interesting, as showing that it was probably borrowed direct from Hottentots or Bushmen—not, as usually assumed, from the Zulus. The same paragraph contains a somewhat perplexing assertion: "In Zulu the employment of clicks instead of diminishing is extending, through the same spirit of tribal self-assertion as may be met with in the Basuto. Whenever a present-day Zulu or even a Kafir" (why "even," seeing that click-words are more numerous in Xosa than in Zulu?) "wishes to coin a new word—and they are doing this on an immense scale—he nearly always introduces a click into it. . . ."

It is difficult to check statements of this kind unless one is in constant touch with natives, but a rough test may be made by consulting the list of neologisms at the end of Colenso's Dictionary (edition of 1905, pp. 721-724). Among 236 words we find only three

containing clicks, and two of these—*isigqoko* "hat" (adapted from *isigcogoo* "head-ring"), and *uTixo* "God"—are not of very recent introduction. As, however, it may be objected that great linguistic changes may take place in seventeen years, we have examined a copy of the native newspaper, "Ilanga las' e Natal," dated February 17, 1922, and find, in two columns, averaging about 175 words each, 31 click-words, excluding repetitions and proper names. Of these, all, with the possible exception of three (two of which may be wrongly printed), are either to be found in Colenso's Dictionary, or are obvious derivatives of words there given.

It is strange to see *-gundu-* "rat" given as peculiar to the Swazi dialect, when *igundane* is very commonly used in Natal Zulu. Similarly, on p. 86, we have, *apropos* of the Sesuto *-liba* "(deep) water," the note, "This is a very interesting penetration far to the south of the Zambezi of a root which is very archaic (*-ndiba* or *-diba*), and particularly characteristic of the N.W. Bantu." But surely it is the same word as the Zulu *isi-ziba*, the Ronga *tiba*, the Swahili *ziwa*, etc.

This survey extends over five chapters and is followed by a similar review of the Semi-Bantu languages, after which we have a highly controversial chapter on phonetics and phonology. The note on p. 215 we may leave to be dealt with by scientific phoneticians, but must protest, in passing, against the dictum that "proficiency in speaking an African tongue exactly as it is pronounced . . . is *only* to be acquired by a parrot-like imitation of the natives" While "parrot-like imitation" can only be compassed by those possessed of a really good ear, a faultless pronunciation can often be acquired even by persons of inferior ear-capacity, by attending to the instructions of the phonetician. But this presupposes an analysis of the sounds carried out with that meticulous accuracy for which our author appears to entertain so great a contempt. Under the heading "Lingual-palatal-sibilant" (p. 217), no notice is taken of the fact that the symbols *c, j* cover at least two different sounds, one of which, the palatal plosive, is *not* a compound consonant "composed of a blending of *t* and *sh*." The difference is important, because sometimes, as in Chinyanja and Zanzibar Swahili, it serves to discriminate between otherwise similar words. Perhaps, however, this point is covered by what is said on p. 222 as to the palatalising of *d* and *t*. The final paragraph of this section (p. 219) fails to make clear the distinction between sentence-intonation and significant word-intonation.

Sir Harry Johnston seems inclined to agree with Prof. Meinhof as to the probable absence of vowel-roots in Proto-Bantu. "A comparison of all the recorded forms often leads to the deduction that the oldest root of two syllables commenced with a consonant, very often a guttural." This term is now disused as not sufficiently precise—it would cover velar, uvular, and faucal consonants. It is not quite accurate, however, to say that Meinhof in all cases "replaced the dubious or missing consonant by a gamma (γ)." He sometimes postulates *ṿ* (bilabial *v*) and has left the question open for at least sixteen stems, where he was unable to decide what the primitive consonant could have been. It is not quite easy to see what is meant by the next sentence: "My own researches, however, lead me in restoring the missing consonant to greater definiteness; to a *g* instead of a γ, a *k* instead of an *x*, a labial instead of an aspirate." The fact that the form *γenda*, for instance, is found in a small group of languages (only Shambala and Pare-Gweno, so far as I am aware), while *genda, jenda*, and *enda* are common, coupled with the greater difficulty of pronunciation of the voiced velar fricative—a difficulty which seems to be felt very generally in Bantu—seem to indicate that Meinhof may be right here.

The chapter dealing with "Prefixes, Suffixes and Concords connected with the Noun" is of great interest. Sir Harry appears to show convincing reasons why the *fi-* or *pi-* diminutive class (Meinhof's 19th) should be identified with the 8th (*vi-*) instead of maintaining a separate existence. That it is singular while 8 is plural constitutes no objection, since we find 14 (*bu-*) fulfilling a similar double function—or rather being treated as plural in some cases (Luganda, Herero, etc.), while in itself it is, strictly speaking, neither singular nor plural. With this example in view, it seems to us that it would have been more logical to place *fi-*, etc. under 8 without creating for it the special subdivision of 8*a*. This prefix occurs in Karanga (as noticed on p. 75) in the form *swi-* (or rather *σi-*, with the peculiar "whistling *s*"),[1] with *ṿu-* corresponding to it as plural.

We should have thought it probable that the "honorific" prefix *ka-* belonged to a different class (now lost as such, but leaving traces, *e.g.* in Luganda, in such words as *Kabaka, Katonda*) from the diminutive (13). There are indications, in Konda, Lamba, and elsewhere, of a class of animals with the prefix *ka-*. Whether this was originally identical with the last-named, or had any connexion with the Chinyanja words beginning with *nanka-* (as *nankabai* "hawk"), is a problem which remains for solution.

It seems a pity to confuse the class of infinitives (verbal nouns) with the locatives in *ku-*, which should properly be Class 17, though no doubt the prefixes had originally the same origin. Words like *kuboko* "arm,"

[1] σ is the International Phonetic Association's symbol for this sound, which (or a similar one) is written by Meinhof ṣ and by Junod ṣ. Sir Harry Johnston has nowhere noticed it.

kutu "ear," etc., are locatives which have quite usurped the place of the original noun—usually of Class 5, which accounts for the plural in *ma-* (*maboko*, *matu*)—the locative, as such, having no plural. Similarly, the locative in *mu-* accounts for the appearance of parts of the body in Class 3. An interesting illustration of this is found in Swahili: the Mombasa dialect has preserved the old word for "foot," *guu* 5 (for *li-gulu*), pl. *maguu*, which, at Zanzibar, has become *m-guu* 3 (properly "in the foot"), pl. *miguu*.

It is a little difficult to accept in its entirety the following: "Class 18 [Meinhof's 20] implies 'hugeness,' something 'gigantic,' 'brutal' . . augmentative in an ugly sense. And Class 19 (*Ga-*) is its plural in Luganda; otherwise the plural applied to *Gu-* is usually *Mi-*." As a matter of fact, the plural *mi-* really belongs to a distinct augmentative class, with the prefix *yi-* or *gi-*; still surviving in Swahili, though now practically indistinguishable from the 5th. The prefix is still traceable with monosyllabic roots, as in *jibwa* and *jitu*—elsewhere (by false analogy) it has been dropped, as in *dege*, augmentative of *ndege*. In Mombasa Swahili, the proper plural prefix of these augmentatives is *mi-*. But these two classes, the Depreciative ("augmentative in an ugly sense") and the Augmentative proper have become hopelessly confused—as shown by the Masaba example, *gumundu*, plural *gimundu*.

It is difficult to estimate duly the enormous amount of labour which has gone to the making of this volume, and not least to the collating and cross-indexing the word-roots grouped under the English equivalents, after having been enumerated separately under their several languages. With all criticisms that may be possible as to matters of detail (easily corrected if the criticisms are found valid), this work must remain for many years to come the standard guide to the subject. Nothing else that has yet been attempted gives the same comprehensive view of the whole Bantu family, and its possible relationships to the languages adjoining on the north-west. Perhaps the examination of these Semi-Bantu forms of speech is the most valuable part of the whole; and the discovery of the Homa and Bangminda languages (hitherto unsuspected forms of Bantu) in the Bahr-el-Ghazal may help to throw light on a difficult question.

A. WERNER.

Chemistry and Medicine.

Préparation des médicaments organiques. Par Ernest Fourneau. Pp. viii+350. (Paris: J. B. Baillière et Fils, 1921). 25 francs.

ONE of the minor effects of the late war has been the increased production of books on technical chemistry in the allied countries. Dealing with the manufacture of organic medicinal substances, hitherto very much a field of German activity, there recently appeared in this country a monograph by Barrowcliff and Carr, primarily concerned with industrial processes, plant, and patents. Prof. Fourneau, on the other hand, describes in the book under review the preparation of organic medicaments on a laboratory scale. Here are exact directions for all stages of the synthesis of phenacetine, stovaine, veronal, salvarsan, and many others, starting from common materials; for each step the yield is given, which in the author's experience can be obtained. A student of organic chemistry who has worked through these will have acquired quite as much manipulative skill as he usually obtains from Cohen's "Practical Organic Chemistry" or Gattermann's "Kochbuch," and he will have made more interesting substances.

The preparative directions constitute, however, little more than a quarter of the book under notice. Prof. Fourneau begins with a theoretical section, discussing such diverse matters as the relative costs of different processes of large-scale production, the pharmacological methods for testing antipyretics, the considerations which should govern the search for a new local anæsthetic, the chances of finding a useful organic compound of mercury. Like the practical section, the more theoretical one is excellent, and worthy of the discoverer of stovaine, but in a different way. The precision of the experimental part, with its homogeneity and wealth of detail, may recall to some readers that its author is a pupil of Willstätter. The more theoretical portion, less systematic than many German books, is, on the other hand, eminently readable. We feel that Prof. Fourneau has chosen for review just those topics in which he was really interested; thus we are given admirable accounts of adrenaline analogues, phosphatides and nucleic acids, in excess of their pharmacological importance, and in greater detail than his rapid review of alkaloidal chemistry.

The advice to beginners on the setting-up of apparatus gives an interesting glimpse of the author's personality. "Il faut toujours se préoccuper du montage soigneux et *élégant* des appareils et y consacrer le temps nécessaire; on le retrouve toujours." The laboratory should be kept like a drawing-room, and Moissan's ideal is quoted that the chemist should be able to work "sans se salir, en habit, en cravate blanche, en escarpins vernis, sur un parquet ciré."

However, the æsthetics of the laboratory do not extend to the printing-office, for Prof. Fourneau's book shows a Latin disregard for Teutonic spelling. Aronsohn (p. 22), Wärmestich (p. 23), Fränkel (pp. 57, 229), Fildes (p. 109), Laidlaw (p. 176), Rosenheim,

Tebb, Thudichum (p. 187), Strecker (p. 188), Zeisel (pp. 219-221) are all spelt more or less inaccurately. We do not for a moment suggest that such trivial errors in typography constitute a serious blemish on an admirable work; we mention them rather in illustration of what we believe to be a national peculiarity. Chemical errors seem nearly all to have been collected in a list of errata, but the structural formulæ of quinine (p. 37) and of trypaflavine (p. 109) still require revision. It is perhaps open to discussion whether quinotoxine (p. 39) can be strictly described as the ketone corresponding to quinine, and whether, in French, phenyl potassium sulphate (p. 236) should really be an "éther sulfonique" (but here we may be getting on dangerous ground).

Prof. Fourneau's book should find a place wherever organic chemistry is taught to advanced students. It may be warmly recommended to the pharmacologist as a source of information on the chemistry of his subject. To recommend to technical chemists a book by the former director of the Poulenc laboratories seems superfluous. George Barger.

The Hegelian Method and Modern Science.

The Ethical Theory of Hegel: A Study of the Philosophy of Right. By Prof. H. A. Reyburn. Pp. xx+271. (Oxford: Clarendon Press, 1921.) 8*s.* 6*d.* net.

THE "Rechtsphilosophie" was the last of the works published by Hegel in his lifetime. Originally it consisted of the rigorous, consecutively demonstrated, chain of numbered paragraphs, which he used as the framework of his courses of lectures. In the form in which we now know it in the collected edition published in 1833 two years after his death, the editors have added the notes and emendations, the celebrated *Zusatze*, with which Hegel was accustomed to elucidate his theory in lecturing.

Prof Reyburn in this admirable study which he entitles Hegel's Ethical Theory, deals mainly with the "Rechtsphilosophie" but treats it as a general introduction to the whole philosophy of Hegel It is doubtful if for the modern student he could have chosen a better way. Hegel had no ethical theory in the technical meaning of the term. His philosophy is ethical theory and his ethical theory is his philosophy. It cannot be otherwise if we once accept the view that the real is the rational and the rational is the real. If there be no realm of existence outside of and indifferent to value there is no need for a transcendental theory of morality like Kant's or a utilitarian principle like Bentham's.

The study of Hegel is of peculiar interest at the present time, and more especially to those who are conscious of the new methodology of science which is manifesting itself in the most modern mathematical and physical theories. So striking indeed is this that had Hegel's place in the history of philosophy been after instead of before the great scientific achievements of the end of the nineteenth and the opening of the twentieth centuries, it would have been impossible to resist the belief that the Hegelian dialectic had been suggested directly to its inventor by the discoveries of science. What finer illustration of identity in difference, of advance by negation, of the union of opposites in a higher synthesis, is to be found than that afforded by the electrical theory of matter? There have been repeated attempts since Hegel to reform philosophy by introducing into it what has been called scientific method, but the great reform which we are witnessing to-day is the introduction of philosophical method into science. Its keynote is that the concrete only is real. Science is discovering that there is no means of giving self-hood, consistency, independence, to the abstract, and this is the alpha and omega of the Hegelian philosophy.

Anyone who desires an easy introduction to the thought of this most powerful and yet most difficult philosopher of the modern period may be recommended to read Prof. Reyburn's book.

H. W. C.

Soaps and Proteins.

Soaps and Proteins: Their Colloid Chemistry in Theory and Practice. By Prof. M. H. Fischer and others. Pp. ix+272. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1921.) 24*s.* net.

THE principal author of the volume under notice, who is a physiologist, states in his preface that he is principally interested in the colloid chemistry of the proteins, that this is too complex for direct analysis, and that therefore he turned to the soaps, as sufficiently analogous to the proteins in their colloidal behaviour to enable one "from the surer ground of the soaps . . . to step over into the more slippery one of the proteins." This view of the possibilities of reasoning by analogy will strike most people as decidedly light-hearted, even in cases where the results to be thus applied are unassailable, a condition which cannot be claimed for the author's views on the nature of soap-liquid systems.

The experimental work described consists in the preparation of a very large number of pure soaps (in the widest sense) and their examination under practically one aspect—their power to form gels with water

and other solvents. The results are used to support the author's theory of the sol-gel transformation, which, according to him, is "a change from what is, at the higher temperature, essentially a solution of *soap in water* to that which is, at the lower temperature, a solution of *water in soap*." The methods of physical chemistry are held to be inapplicable to the latter type, and the author is thus relieved of the task of considering the fundamental work of McBain and his school. Various experiments are quoted in support of this gel theory, thus (p. 80): "A drop of phenolphthalein solution dropped upon a 10 per cent. sodium stearate water gel remains uncoloured. If, however, the gel is slightly squeezed (which breaks the encircling hydrated sodium stearate film and squeezes out the enclosed solution of soap-in-water), the spot turns bright red." If any one will take the trouble to put a drop of indicator on an acid or alkaline gelatin gel, he will see it turn without squeezing, so that the behaviour of soap gels is not, as the author claims, typical or universal, nor is it any clue to that of protein gels.

The chapters on proteins are trifling, and analogies like that drawn between the heat coagulation of albumin and the behaviour of a boiled solution of sodium palmitate can scarcely be taken seriously. The author almost throughout dismisses the work of other investigators in the airiest fashion, most strikingly, perhaps, in his chapters on emulsions and froths. Surface and interfacial tensions, adsorption and film-formation are all irrelevant: the decisive factor is a curious and novel physical property of the phases, their "breaking length." An extraordinary feature of the book are the illustrations—half-tones of more than 1,300 tubes and bottles containing soap solutions which, at their worst, convey nothing and, at their best, no more than the text. They may in part account for the high price of the book, which is difficult to explain on any other grounds.

Commercial Metallurgy.

The Metallurgy of the Common Metals: Gold, Silver, Iron (and Steel), Copper, Lead, and Zinc. By L. S. Austin. Fifth edition, revised and enlarged. Pp. xviii+615. (New York: J. Wiley and Sons, Inc. London: Chapman and Hall, Ltd., 1921.) 42s. net.

THE first edition of Prof. Austin's book was published in 1907; it has now reached a fifth edition. In his preface the author states that since 1913, the date of the last edition, such radical changes and improvements have been made in the metallurgy of the common metals that the present book has been largely rewritten to bring it in accord with present-day practice. It is refreshing to come across a book which treats metallurgy as a whole and does not, as is so frequently the case, subdivide it into the so-called ferrous and non-ferrous metallurgy. The practice of differentiating the metallurgy of iron and its alloys from that of the other metals has its origin, of course, in the outstanding practical importance of these materials and the scale on which they are manufactured, but there is no scientific reason for making any distinction of this kind, and indeed, there is little doubt that if there were more interchange of opinion between those engaged in the various metal industries it would be of considerable benefit to all concerned.

The first ten chapters deal with general metallurgy under the headings (1) ores and metals, (2) fuels, (3) refractories, (4) the preparation of ores, (5) crushing, grinding, screening, and classifying, (6) metallurgical furnaces, (7) combustion, (8) metallurgical thermochemistry, (9) roasting, and (10) concentration of ores. Inasmuch as these aspects of metallurgy are compressed into 117 pages, the treatment is necessarily somewhat brief. The author, however, has economised space in not attempting to describe methods not now in use. Compactly as the subjects are dealt with, it would appear that terseness has been carried to an extreme in attempting to describe the concentration of ores by gravity, by concentrating tables, and by oil flotation in three pages, a considerable part of which is occupied with diagrams.

The remainder of the book treats of the metallurgy of gold, silver, iron, copper, lead, and zinc in so far as extraction and refining processes are concerned. No attempt, however, is made to deal with the mechanical treatment of metals, either in the hot or cold state, nor their working up into finished products. One of the characteristic features of American metallurgy is its emphasis on the efficient mechanical handling of the materials used in producing the metals and it is natural, therefore, to find this aspect of the subject well treated. The author's account of the metallurgy of gold, silver, copper, and lead is, on the whole, satisfactory. The metal iron, however, receives something less than its share of credit, for an attempt is made to describe the production of wrought iron in less than three pages. To try to deal with the manufacture of wrought iron without any account of the mechanical treatment necessary, except in the most perfunctory fashion, is certainly unusual. With regard to zinc, it is somewhat curious that, considering the importance of the present-day production of electrolytic zinc, very little more than one page is devoted to it.

The last two chapters give a brief account of plant and equipment and their cost and the business of

metallurgy. A satisfactory feature of the book is the calculation of furnace charges in reference to typical metallurgical operations. As has been generally indicated, the book gives a good, if at times too brief, account of the principal operations involved in the metallurgy of the six metals discussed. It is well printed, particularly well illustrated, and bears evidence of careful and judicious preparation.

H. C. H. C.

Scientific Activities in the United States: A Biologist's View.

Universities and Scientific Life in the United States. By Prof. Maurice Caullery. Translated by James H. Woods and Emmet Russell. Pp. xvii+269. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1922.) 10s. 6*d*. net.

BEFORE the war inter-university exchange of professors was much in vogue as between Germany and America. More recently several exchanges of this kind have taken place between America and France, and Prof. Caullery's book is a result—a very useful result—of one of these exchanges. It gives a remarkably lucid and sympathetic interpretation of impressions received by the writer during a stay of five months in America in 1916, when he filled the post of exchange professor of biology at Harvard and visited many of the principal seats of learning in the United States.

The greater part of the book is devoted to the universities and colleges as centres of research and as providing the environment in which future workers are trained. These institutions have, in general, envisaged as their main task the training and equipment of their students for successful leadership in all branches of social activity; and they have come to recognise that with the incessant extension of the fields of application of science to social needs it concerns them to provide the best possible teaching in applied as well as in pure science. Thus the tendency is for science, as the basis of preparation for practical life, to inspire all the activity of the university.

It is sometimes asserted that the study of science in America is apt to be cramped by an excessively utilitarian bias, and such a bias has undoubtedly characterised the State universities, most of which originated in the "Colleges for Agriculture and Mechanic Arts" established under the Morrill Act of 1862. The policy inaugurated by this Act was one which Congress adopted owing to the refusal of the independent colleges to provide urgently needed teaching in technology. About the same time the growth of scientific knowledge led to the breaking down of the old uniform curriculum and its replacement by the elective system, and to the organisation of "Graduate Schools" by the more important colleges, which thus became full universities and began to cultivate a spirit of original research. Competition with the new State universities soon led to the abandonment of the attitude of aloofness in regard to applied science and proved beneficial to the interests of pure science, both because the broadening of the basis of studies in the old institutions brought them into closer touch with the nation at large and greatly increased their prosperity and resources, including laboratory equipment, and because the State universities have made, and continue to make, successful efforts towards rivalling the others in the cultivation of scientific research of all kinds.

In this connexion Prof. Caullery is able to elucidate and point his argument by reference to science progress in French institutions, where the Napoleonic system of public instruction has shown itself deficient in adaptability to changed conditions and faculties of science have few points of contact with schools of technology. In America adaptation to their environment is reflected in the remarkable growth shown by the universities and colleges during the past thirty years. The student population of the collegiate and graduate departments has twice doubled within this period, and shows, according to statistics summarised recently in NATURE of April 1, p. 425, no tendency towards abatement of this rate of progress. Buildings and equipment have more than kept pace, their value having increased from 108*l*. to 279*l*. per student, and this is due largely to the enormous development of laboratories which has taken place in all branches of science. Recent visitors to the United States are unanimous in admiring the wealth of material equipment for science teaching and research, and some even describe it as excessive. This development has been made possible by a belief, prevalent among all classes of the community, in the practical value of such work and, especially for the private universities, by the spirit of intense loyalty to the Alma Mater on the part of college graduates. The Harvard rule, that at the twenty-fifth anniversary of graduation each class gives the university a sum of 100,000 dollars, affords an example of the very practical forms in which this spirit manifests itself.

When the Graduate School movement began there arose a demand for facilities for scientific research, and, as this could not at the time be met in America, students resorted to Europe, and found that of European countries, Germany best suited their requirements.

tradition of Germany's scientific supremacy became firmly established, and for forty years America's most promising young workers, coming under the spell of this tradition, became for life "intellectual subjects of Germany." A reaction had begun to set in before the war, and has acquired considerable force, but the German influence on American science has been profound and its effects will be lasting.

Scientific research is unanimously recognised by American intellectuals as an essential function of the university, but while the material requisites for it have been abundantly supplied, there exist certain other conditions less favourable to its development. Students come up to the university ill prepared as regards both acquisition of knowledge and intellectual discipline. Like many other observers, Prof. Caullery regards secondary school teaching as the weakest part of the American system of education. It is, he says, not merely that the college is burdened with the task of imparting knowledge which should have been acquired in the high school, but that the schools defer too much to the taste, or rather whim, of the pupil. "Americans try to compel the child as little as possible, to present life to it under its most smiling form, to spare it opposition, to make work appear to it under the form of pleasure rather than of duty . . . ; they treat the schoolboy too much like a student, to the detriment of healthy intellectual discipline." The "spoon feeding" which is consequently resorted to in the college (where the student is apt to be treated too much like a schoolboy) is unfavourable to the development of capacity for original work. While this does not prevent the colleges from turning out graduates well qualified to achieve success in life, nor stifle the development of exceptionally gifted individuals, in the average case the college gives "a culture not sufficiently deep to be fertile."

The connexion between the college and the graduate school of the University, in which most of the advanced work in pure science is done, is very close. In all except a few of those universities (about thirty) in which a graduate school has been developed, it has no separate teaching staff; its professors are also those of the undergraduate college, although the work is organised quite separately, and is carried out under the superintendence of the Dean of the school. In most universities, moreover, the college tradition, with its emphasis on athletics and the social side of life, is still dominant. Some high authorities in America who believe that the destiny of the universities is to become primarily great schools of research have urged that the time has come to free the graduate school from this domination. Meanwhile there is a clear tendency to create special institutes for research within more or less narrow limits, some being established within, or in association with, the universities and others with no such connexion.

As regards the actual contributions to science of American universities, Prof. Caullery notes that in zoology and general biology, the sciences in which he is specially interested, they have produced of late years many very remarkable works. He instances those of Edmund Wilson (cytology), E. Conklin (cell-lineage), R. G. Harrison (experimental embryology), T. H. Morgan (Mendelian heredity and mutations in Drosophila), Calkins and Woodruff (Infusoria, senescence, etc.), and others.

Scientific activities outside the universities and colleges are dealt with by Prof. Caullery in a series of interesting sketches of the more important of the research institutes, the Carnegie and Rockefeller and other foundations for promoting research, the great museums, the Federal scientific services, and the scientific academies and societies. From the first category the Mellon Institute for Industrial Research may be selected as an example of an establishment for pure research attached to a university—Pittsburgh—but retaining a large measure of autonomy. A manufacturer having a problem to solve turns it over with a definite sum of money to the Institute, which proceeds to engage the services of a man of science and provides the requisite laboratories and equipment. The man of science, who is styled a fellow, conducts his researches in secrecy, and the results are the property of the donor of the subvention. The plan is reported to have worked very successfully.

For an indication of the scale on which scientific research is being fostered by these various bodies (except the Federal services) and by great industrial corporations, one may refer to a bulletin published last year by the National Research Council, now the chief agency for co-ordinating scientific research in America. This bulletin (noticed in NATURE of August 4 last) enumerated 170 bodies other than universities and colleges which provided funds for this purpose of the aggregate annual value in 1920 of more than 18 million dollars. The Government (Federal and State) grants for research in agriculture, engineering, and the industrial arts have been estimated to amount to 10 million dollars in 1921.

Our Bookshelf.

A Text-book of Wood. By Herbert Stone. Pp. vii + 240 + 41 Plates. (London: Rider and Son, Ltd., 1921.) 21*s*. net.

THIS book deals with the anatomy, physical and mechanical properties, anomalies, defects, and decay of wood. Although intended for "advanced students,"

it abounds in elementary errors as regards facts, botanical and mechanical. For example, the account of the production of wood by cambium is truly fantastic, while the implication is made that when dead wood is absorbing water and swelling, the cells of the medullary rays exert great pressure by reason of their turgidity. But quite inexcusable are misquotations of various scientific workers, including R. Hartig and Mathieu (who is made responsible for the statement that heartwood and sapwood are synonymous "expressions").

Errors as regards matters of fact are matched by the author's methods of reasoning and the conclusions that he draws. According to him the wood-vessels cannot have very important functions, "inasmuch as Conifers do without them." Or, again, he writes of a beam under transverse bending load that "the height may be reduced and yet the beam be stronger"; and in dealing with mechanical tests he not only "hopes and believes," that practical men do not "pay any attention to the figures so far supplied by physicists," but also advises the abolition of "all calculations whatsoever." A number of excellent photographs of wood-structure impart some value to the book.

Textile Design and Colour: Elementary Weaves and Figured Fabrics. By W. Watson. Second edition, with an Appendix on Standard Yarns, Weaves, and Fabrics. Pp. xi+436. (London: Longmans, Green and Co., 1921.) 21s. net.

THE comprehensiveness of Mr. Watson's training is reflected from the pages of this book. A student in the Textile Industries departments of the University of Leeds and the Bradford Technical College, and successively head of the Textile Departments at Salford and the Royal Technical College, Glasgow, Mr. Watson has naturally produced a volume which is both broad in outlook and sequential in treatment. In the maze of small weave effects, for example, it is so easy to degenerate into mere statement and illustration that any writer who can introduce a sequential and reasonable treatment leading to that imaginative insight, which is so much to be desired in the cloth constructor, is to be congratulated. In the future probably more conventional scientific treatment of the structures here referred to will be necessary, for not only do such matters as combinations and permutations appear, but, as was quite accidentally discovered at the meeting of the Mathematical Association last year, the problem of sateen cloth structure is the problem of atomic grouping in crystal structure.

Mr. Watson's treatment of the colour problems involved in textile designing is by no means so satisfactory: it largely resolves itself into "colour and weave" form. The technical treatment of figured fabrics is excellent, and the appendix upon Standard Fabric should prove very useful to all designers and manufacturers.
A. F. B.

Principia Ethica. By Dr. George Edward Moore. Pp. xxvii+232. (Cambridge: At the University Press, 1922.) 15s. net.

THIS volume is the reprint of the famous and much-discussed treatise of Dr. G. E. Moore, the present Editor of *Mind*, which was first published in 1903. Readers will turn at once with interest to the brief note added to the preface in which the author tells us that he is still in agreement with its main tendency and conclusions. His thesis is that "good" is indefinable, but that "the good" can be defined. The good is the thing, simple or complex to any degree, to which the indefinable predicate good belongs. He illustrates his meaning by an extreme case. He asks us to imagine a world exceedingly beautiful, and then to imagine the ugliest world it is possible to conceive. We are asked, in comparing these worlds, to accept the limitation that "we are not entitled to imagine that any human being ever has, or ever, by any possibility, *can*, live in either." Is it irrational, he asks, to hold that it is better that the one should exist and not the other? To most students of ethics the limitation makes the question nonsense in the literal meaning of the term. It is interesting to find that Dr. Moore can still think it a rational question after the lapse of twenty years. Yet we must admit the force of his logic, for if value is to have any meaning at all to the realist, it can only be by finding some way of attaching it to the object and presenting it in complete abstraction from the subject, for the mind is limited in its activity to contemplation.

Rocks and Fossils and How to Identify Them. By J. H. Crabtree. Pp. 63. (London: The Epworth Press; J. Alfred Sharp, n.d.) 1s. 9d. net.

WE have here a book, very prettily illustrated by photographs; but the text is not in keeping with the author's daring statement that "geology is, of all concrete science studies, most exact in its observations and conclusions." The loss of land at Dunwich (p. 14) should not be ascribed to subsidence; faults (p. 18) do not imply that "the two parts are pitched at different angles"; limestones are said to be "generally combined with mineral matter"; Radiolaria are photographed in one of the admirable plates as "flinty shell remains of foraminifera"; and in another plate a very mixed assemblage of fossils, including halysites and Fenestella, is attributed to the Old Red Sandstone. "Interlocking teeth" are given as a characteristic of Labyrinthodon, and Tyrannosaurus is said to have preyed upon the mammoth. We must not dilate on the reappearance of Eozoon and the "Laurentian system," or on the "boreal climate" of the Trias (p. 56). If we interpret his remarks on "sauroid fishes" as referring to Saurıpterus, the author has been diligent in his reading, and we must regret that he has shown so little regard for exactitude in "observations and conclusions."
G. A. J. C.

The Mineral Resources of Burma. By N. M. Penzer. (Federation of British Industries: Intelligence Department.) Pp. viii+176. (London: G. Routledge and Sons, Ltd.; New York: E. P. Dutton and Co., 1922.) 31s. 6d. net.

MR. PENZER, on behalf of the Federation of British Industries, has undertaken with conspicuous success the task of summarising the information hitherto inconveniently scattered through various unrelated publications concerning the mineral resources of the province of Burma. He has taken care to secure the co-operation of recognised authorities with special

ocal experience, such as Sir George Scott, Mr. La Touche, and Dr. Coggin Brown; and the result is a reference work of exceptional value to prospectors and commercial men. In addition to precise summaries of the recorded information regarding each mineral occurrence, the book contains a very useful sketch of the physical geography, geology, history, administrative systems and communications of Burma, a full index to the local vernacular names in common use, and a very full, conveniently classified bibliography.

The Statesman's Year-Book: Statistical and Historical Annual of the States of the World for the Year 1922. Edited by Sir John Scott Keltie and Dr. M. Epstein. 59th Annual Publication. Revised after Official Returns. Pp. xlvii+1568. (London: Macmillan and Co., Ltd., 1922.) 20*s*. net.

THE new edition of the "Statesman's Year-Book," which appears earlier than usual this year, maintains all the features that have gained for it a unique place among volumes of reference. The number of independent states has now been increased by the addition of Egypt and Lithuania. Various secession states, the status of which is not yet fully recognised, are still grouped with their parent countries. The organisation of the Irish Free State, together with the full Treaty between Great Britain and Ireland, are given in the introductory pages, which also furnish information on the organisation of the League of Nations and the Imperial and Washington Conferences. While the whole volume has, as usual, been carefully revised, special attention has been devoted to Russia and China. We note some discrepancies in the figures for area and population of the countries detached from Russia, as given under the heading of Russia, and of those countries respectively; but the last census returns in this part of Europe were by no means complete. Two coloured maps show the division of Upper Silesia by the League of Nations and the Burgenland settlement between Austria and Hungary.

The Annual Register: A Review of Public Events at Home and Abroad for the Year 1921. Pp. xii+332+180. (London: Longmans, Green and Co., 1922.) 30*s*. net.

THE scope of the "Annual Register" is well indicated by its sub-title, and a truly remarkable amount of information is gathered together within the covers of the volume. Part 1 consists of some three hundred pages, of which about half are devoted to events of importance occurring in England during the past year: a large portion of this section deals with events in Ireland, culminating with the Peace Conference in London and the signature of the treaty of peace. The remainder of Part 1 is devoted to brief summaries of outstanding events in other countries of the world. Part 2 is of a more general nature and contains, among other items, a retrospect of science during the past year. The section is divided into two parts dealing with the biological and physical sciences respectively, and all outstanding events in the world of science appear to be mentioned.

To cover the ground, the articles are of necessity brief, but the whole is welded together so skilfully that the volume, besides serving as a comprehensive reference book for world affairs, provides an interesting and readable account of man's activities during the year 1921.

Cotton Spinning. By W. Scott Taggart. Vol. II. Sixth edition with Appendix. Pp. xv+291. (London: Macmillan and Co., Ltd., 1921.) 8*s*. 6*d*. net.

IT is not surprising that Mr. Scott Taggart's work on "Cotton Spinning" should already be in its sixth edition. Books of this type arrange themselves under one of two heads—either they are "descriptive" or they are "demonstrative"; rarely are they both. This work, although by no means void of the "why" and "wherefore" and the "for" and "against," is mainly descriptive. Thus in dealing with the distribution of drafts on pages 259 to 266, "fibre movement" does not seem to have been considered, with the result that even here Mr. Taggart is in difficulties in making theory fit with practice. But the treatment of each section of the subject throughout is so clear and concise that even the very limitations of the treatment stand out clearly and thus are not dangerous. This book should certainly be in the hands, not only of every cotton spinner, but of every spinner of materials of a like nature. A. F. B.

A History of the Association Psychology. By Prof. H. C. Warren. Pp. x+328+1 chart. (London: Constable and Co., Ltd., 1921.) 16*s*.

THE volume under notice, by the well-known professor of Princeton University, contains a great deal of matter which cannot fail to be useful to the student, and it is presented in a serviceable form. It is not, however, as the title would lead us to expect, a history of the movement in mental science which followed the adoption of the empirical principles of Hume and explained knowledge by the laws of association,—a theory often described by its critics as psychological atomism. It is rather an attempt to show that an idea which has no history is to be discovered in all the historical systems of philosophy. It begins with the ancient philosophy of Greece and ends with an account of some of the psychological experiments now being conducted in college laboratories and reported in current journals.

Lubricating and Allied Oils. By E. A. Evans. Foreword by Sir Charles Cheers Wakefield. (The Directly-Useful Technical Series.) Pp. xv+128. (London: Chapman and Hall, Ltd., 1921.) Price 9*s*. 6*d*. net.

THE greater part of this book is taken up with descriptions of the physical and chemical tests usually carried out on oils with the view of determining their commercial value. Sufficient is given to enable the chemist to carry out these tests in the orthodox manner and to reduce the results. The book should also be of value to the engineer, who must understand the meaning of the experimental results; his requirements are considered in later chapters on the selection of lubricants and oils employed in practice. Most of the existing works on lubrication and lubricants are too comprehensive and technical to be of much service to the user of oils, and the author of the present work is to be commended for the brief and clear account of the principal properties he has presented.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Interspecific Sterility.

THE implications of modern genetics have been so little considered by biologists in this country that the criticism of my address by Dr. Cunningham (NATURE, June 17), though in purpose destructive, is not unwelcome. Of the points he raises one chiefly calls for reply. I directed once more the attention of naturalists to the fact that we still await the production of an indubitably sterile hybrid from completely fertile parents which have arisen under critical observation from a single common origin. So far as our knowledge goes, all the domesticated races—for example, of dogs, of pigeons, of fowls among animals; and of cabbages, of peas, of *Primula sinensis*, and many more among plants—when intercrossed among themselves never produce this sterility in their mongrels, though the races are often distinct enough to pass for species. But if we begin crossing natural species, even those which on our reckoning must be very closely allied, we constantly find either that they will not interbreed, or that, if they can be crossed, the result is more or less sterile. Dr Cunningham takes exception to my speaking of this interspecific sterility as the chief attribute of species, but he will not dispute that it is *a* chief attribute of species.

The races of fowls might, as he holds, on account of their enormous divergences, be without impropriety compared to natural species. They may also, as he thinks, all descend from *Gallus bankiva* (though I find that difficult to believe), but inasmuch as they do not show interspecific sterility they do not help us to understand how that peculiar property of species arose in evolution. In contemporary variation we witness the origin of many classes of differences, but not this; yet by hypothesis it must again and again have arisen in the course of evolution of species from a common ancestry. The difficulty is no new one, but I emphasised it because naturalists should take it more seriously than they have done hitherto. Especially now that a great deal of experimental breeding is in progress, watch should be kept for such an occurrence. I by no means declare that the event cannot happen, but, so far as I know, it has not been witnessed yet.

Dr. Cunningham tries to fill the gap by adducing two instances. The first is that of *Oenothera gigas*. Now I had not forgotten the tetraploids, which so often do not breed freely with diploids, but the applicability of that example is exceedingly doubtful. Interspecific sterility or incompatibility may well be a consequence of nuclear diversity, though we can scarcely regard an unresolved pair of twins, such as the tetraploid must be, as a specifically distinct organism.

His second illustration, if authentic, would be more nearly what is wanted. He says that "two mutants of Drosophila in Morgan's experiments are almost completely sterile with one another." The allusion is probably to a paper of Metz and Bridges (Proc. Nat. Acad. Sci., 1917, iii. p. 673), in which they claimed to have found two mutants of *D. virilis* which gave partially sterile hybrids when intercrossed. Dr. Cunningham is not perhaps aware that this claim was afterwards withdrawn (Metz, *ibid.*, 1920, vi. p. 421), inasmuch as one of the mutants was found to have been partially sterile. Metz and Bridges did adduce another example in *D. ampelophila*, but for a variety of reasons that, even if substantiated, would scarcely be to the point. As a matter of fact, however, in so far as opportunity of repeating the cross has occurred, complete fertility resulted. I know of no other example to which Dr. Cunningham can be referring.

Mr. Crowther (NATURE, June 17, p. 777) mistakes my meaning. It is, as he says, not difficult to "imagine" interspecific sterility produced by a gradual (or sudden) modification. That sterility may quite reasonably be supposed to be due to the inability of certain chromosomes to conjugate, and Mr. Crowther's simile of the sword and the scabbard may serve to depict the sort of thing we might expect to happen. But the difficulty is that we have never seen it happen to swords and scabbards which we know to have belonged originally to each other. On the contrary, they seem always to fit each other, whatever diversities they may have acquired.

W. BATESON.

July 2, 1922.

Geology and the Nebular Theory.

I DO not deserve the reproaches of Prof. Coleman (NATURE, June 17, p. 775). My molten earth did not, in point of fact, owe its thermal energy to primitive condensation, but to accumulated radioactive heat, as the concluding part of my lecture might have shown. I am committed neither to the nebular theory nor to the planetesimal theory.

Had I adopted the wider definition of the Archæan favoured by Prof Coleman, I could not, of course, have described the Archæan sediments as scanty. I referred to an Archæan limited to the Keewatin, and to the Laurentian outpourings of granitic materials. The Keewatin is generally described as mainly volcanic in origin. The definition of Archæan and Algonkian favoured by Van Hise and Leith (Bulletin 360 of the United States Geol. Survey) would bear me out.

While many geologists would agree with Prof. Coleman as to his estimates of Archæan sediments, many, I think, will disagree with him in his contention that there was nothing exceptional in the thermal conditions attending the Laurentian revolution. Prof. Coleman's most interesting discovery of an ice age in Huronian times has, I submit, nothing to do with the matter. On the other hand, I think geologists in their interpretation of the Archæan should keep in mind the possibility (or probability) that the phenomena observed are due to paroxysmal thermal developments traceable to deep-seated radioactive substances: and that these developments, which appear to have been world-wide in extension, may have been sufficiently intense to have closed a biological era. So that, in fact, we have in the Archæan the almost obliterated record of a prior geological age.

J. JOLY.

Trinity College, Dublin.

I HAVE read with interest Prof. Coleman's timely reminder, in NATURE of June 17, p. 775, of the essentially intrusive relations of the Archæan and of the frequently made deduction that the oldest visible rocks of the earth's surface are sedimentary. Of course this deduction is perfectly sound, provided the age of an intrusive rock is taken, as has been the

custom, [illegible] We are [illegible] however, [illegible] history [illegible] material composing these intrusive Archæan masses, and, in view of their predominantly banded structure, which marks them off as in some way different from later intrusive masses of similar composition, such consideration seems forced upon us.

Now the banded character of the Archæan gneiss suggests a partial derivation by melting from some stratiform materials such as sedimentary or volcanic rocks, or at any rate from rocks showing marked small-scale differentiation into basic and acid types. I do not think that stratiform differentiation during or previous to crystallisation can be seriously put forward as a cause of the banding, in view of the rarity of this phenomenon in more recent granites, and the fact that in them it is largely a marginal effect.

May we not then have in these Archæan gneisses the recrystallised remnants of still older sediments and lavas, and who is to say that they may not also embrace portions of the original surface on which water first settled, but so obscured by recrystallisation that the question of its molten or planetesimal origin is now unsolvable?

The difference between the two views is simply that one regards the history of sedimentation on the earth as cut off sharply by intrusion, while the other sees it extending still further back into the mists of the past, beyond the point where human vision is any longer capable of discrimination. Where, on either view, is the decisive criterion between the nebular and planetesimal hypotheses?

W. B. WRIGHT.

Manchester, June 27, 1922.

Wegener's Displacement Theory.

WEGENER's speculations have attracted so much attention that there must be many who would be glad to find some simple means of testing his fittings and coincidences for themselves. Owing to the distortion present in all maps such tests must be carried out on a globe. Wegener himself uses tracing paper, which must be cut and slashed in order that it may even approximately fit the surface; and any one who has tried it will admit that it is difficult to obtain satisfactory results. An easier plan is to roll out a lump of modelling wax or plasticine into a sheet of moderate thickness. The sheet may then be pressed upon the globe and cut to the required shape. According to my own experience, the best method is to cut the sheet a little smaller than the area that is to be represented, so that the actual margin appears all round it, and to build it outwards to this margin by the addition of small pieces of wax. Old plasticine which has become rather dry works very well and does not stick to the globe.

But much more precise tests can be carried out with the help of some form of triangular compasses. The three points of the compasses may be placed on three critical points of the globe and afterwards transferred, without altering their relative positions, to any other part of the globe that may be desired. The ordinary triangular compasses of the draughtsman are very little use upon a spherical surface, but a fairly convenient instrument can be constructed with an ordinary one-jointed two-foot rule as its basis. A point about an inch long is fixed near the joint, and each arm is provided with a sliding carrier. Each carrier bears a short sleeve through which a pointed rod, such as a knitting needle, slides rather stiffly. These rods form the other two points, and all three should stand approximately at right angles to the plane of the rule.

This is an easily constructed type, but much more convenient forms can be devised. If, for example, the arms are arcs of circles, of suitable diameter, so that they may stand concentric with the globe, the points may all be of fixed length, and the most troublesome of the adjustments required by the straight-armed form will be avoided.

This is not the place to discuss Wegener's views, but the use of triangular compasses seems to show that a rather high degree of plasticity is necessary in the masses of "Sial" in order to produce the coincidences on which he bases his calculation of the probability that his theory is correct.

PHILIP LAKE.

Sedgwick Museum,
Cambridge, June 21.

Opalescence Phenomena in Liquid Mixtures.

IT is well known that liquids which mix completely above a certain critical temperature, *e.g.* phenol and water, exhibit a strong and characteristic opalescence as the temperature of the mixture is lowered to a point slightly above that at which the components separate. A quantitative theory of this phenomenon was put forward by Einstein (*Annalen der Physik*, vol. 33, 1910) on the basis of thermodynamical reasoning, the spontaneous local fluctuations of *concentration* of the mixture being taken into account and the light-scattering due to the resulting fluctuations of refractive index being evaluated. He obtained as the expression for the light-scattering

$$\pi^2(M/N\lambda^4)\,.\,v\left(\frac{\partial\mu^2}{\partial\kappa}\right)^2\Big/\frac{\partial(\log p)}{\partial\kappa}\ \text{per unit volume,}$$

where μ is the refractive index of the mixture and $\partial(\log p)/\partial\kappa$ expresses the rate of change of the vapour pressure of one of the components with concentration, a quantity which becomes very large as the critical temperature and concentration are approached, thus giving rise to a marked opalescence. It should be pointed out, however, that Einstein's expression does not include the whole effect, for we have also to consider the result of *the fluctuation of density of either component taken separately*, and to add to Einstein's formula

$$(\pi^2/18)(RT/N\lambda^4)[\beta_1(\mu_1^2-1)^2(\mu_1^2+2)^2 + \beta_2(\mu_2^2-1)^2(\mu_2^2+2)^2],$$

where β_1, β_2, μ_1, μ_2 are respectively the compressibilities and refractive indices of the components. Further, the light-scattering due to the anisotropy and arbitrary orientation of the molecules of the components has also to be added.

The result of these corrections of Einstein's investigation may briefly be indicated. Very near the temperature at which the mixture separates into two phases, the fluctuations of *concentration* contribute by far the larger portion of the effect. But at higher and lower temperatures the effects of fluctuations of *density* and molecular anisotropy are no longer negligible, and when the temperature is sufficiently removed from the critical point they form a substantial part of the whole. Further, the increase in relative importance of the effect of molecular anisotropy in these circumstances should result in an increase in the proportion of *unpolarised* light in the transversely-scattered beam as we recede from the critical temperature.

The foregoing indications of theory have been confirmed generally in a series of experiments over a wide range of temperatures on light-scattering in phenol-water mixtures undertaken under the writer's direction by Mr. V. S. Tamma. It is found that the increased opalescence of the mixture over

and above the effects due to the components taken separately can be traced at temperatures far higher than the critical point, and the indicated changes in the polarisation of the scattered light are also easily observed.

It is clear that the case of liquids which are completely miscible at ordinary temperatures stands on the same footing as that of imperfectly miscible liquids above the critical temperature, and the recent observations of W. H. Martin on this point (*Jour. Phy. Chem.*, Jan. 1922) agree with the indications of the theory outlined above.

I may take this opportunity of directing attention to a very important result observed in experiments on light-scattering in liquids conducted by Mr. Seshagiri Rao and the writer. It is found that the molecular anisotropy which results in a scattering of unpolarised light is noticeably *a function of the frequency of the incident light.* This indicates that the anisotropy is really due to the difference of the optical frequencies of the molecule in different directions, a conclusion which has a bearing on the recent interesting work of Havelock (Proc. Roy. Soc., May 1922). Debye and others have suggested that some molecules possess an appreciable permanent electric moment, and would thus exercise perceptible orienting influences on each other even in the gaseous and liquid states. Indications are already forthcoming that this may exercise an observable influence on the phenomena of molecular scattering of light.

Finally, it may be mentioned that a very carefully carried out series of experiments on the light-scattering in ether, benzene, and normal pentane, over a large range of temperatures above and below the critical temperature, has confirmed quantitatively the Einstein-Smoluchowski theory of molecular scattering of light. C. V. RAMAN.

210 Bowbazar Street,
Calcutta, May 25, 1922.

Transcription of Russian Names.

MR. DRUCE's letter in NATURE of June 17, p. 777, makes little of my typographical objection to a Czech transcription for the names of Russian men of science, by saying that NATURE and other journals already employ letters with diacritical marks. For my part, I venture to estimate that not one in twenty English newspapers has Czech type among its founts, or, if it had, would know how to use it in transcription. Are, then, Russian scientific names to be rendered on one system in NATURE and on another in almost every other newspaper—or even book? And are Russian scientific names to be rendered differently from Russian literary and musical names—or place-names?

Nobody questions that it is possible, and indeed easy, to transliterate Russian into Czech, all Slavonic tongues being closely akin. But is it more helpful to Britons to render ч by *č* than by *ch*, or ц by *c* than by *ts*, even though you save a letter by doing so? (I wonder how many Britons would pronounce this "c" correctly!) Czech journals naturally transcribe Russian names into Czech, but that seems to be no reason why journals in other languages should do so.

Mr. Druce, by the way, ignores my remark that Serbo-Croatian, with its ready-made official system of transliterating Cyrillic into Latin characters, has as good a claim as Czech, if a Slavonic language is to be used for this purpose.

Surely what is wanted in this country to replace the old conventional French and German (and hybrid) forms of Russian names is not a Croat nor a Czech system, but an intelligible British system of transcription, uniform for all Russian names alike; and this we have ready-made in the R.G.S. II. system (obtainable at any of the geographical booksellers, or at the Royal Geographical Society). Why not use it? EDWARD GLEICHEN.

Royal Geographical Society,
Kensington Gore,
London, S.W.7, June 23.

The Influence of Science.

THE defect of the disappearance of Greek from scientific education makes itself felt in the treatment of the history of science (NATURE, June 24, p. 801). The controversy between Galileo and the Inquisition was carried out with pretended hostility, but amicably in reality in the manners of good scientific society, as an academic university disputation on an agreed accepted thesis, taken from Plutarch's "Aetia Physica," the source of such disputations as "An detur vacuum?" or "de tempore," or whether the tide is due to the influence of the moon.

The Pythagoreans were prepared to maintain against all comers that the sun was the centre of our cosmos, in opposition to the Stoic philosophers; and so on for other subjects of disputation in the University of Athens.

Mr. Lones, of the Patent Office, has retrieved for us at last the passages in "De caelo" and elsewhere, of Aristotle that set Galileo to make a test by experiment, with the two weights dropped from the Campanile of Pisa, of density such as not to be affected appreciably by the resistance of the air. The weights struck the ground with one thud apparently; but if Galileo had thrown himself over after, his thud would have been distinctly later.

Because Aristotle was discussing the terminal velocity of rain and hailstones, or even a meteoric stone, from a height high up in the air, the ascent of a bubble in air, or else in water, compared with a stone sinking; he had no air-pump except his lungs, he could not be certain whether air was really a substance in Nature.

"Don'ts for Students in Science and History," compiled by G. S. Boulger (Tract 74, Catholic Truth Society), should be consulted before accepting the common version of many similar controversial stories. Huxley is quoted, writing to Prof. Mivart in 1885: "I gave some attention to the case of Galileo when I was in Italy, and I arrived at the conclusion the Pope and College of Cardinals had rather the best of it." And so the Inquisition was entitled to a parting shot of jubilation, as it would be again to-day on the doctrine of Relativity.

The rival theories of the Greek philosophers could serve as dialectical exercises till the crucial experiment of the "optic tube of Fiesole"; and here Galileo destroyed all previous uncertainty by his use of the telescope, the most powerful instrument in history for revolutionising the ideas of science.

G. GREENHILL.

Staple Inn, June 27, 1922.

[Fortunately, inability to maintain a scientific thesis before philosophic or other authorities no longer involves such penalties as those to which Galileo was subjected. The whole purpose of the article to which Sir George Greenhill refers was to show that the freedom of experimental inquiry thus secured had far-reaching social and intellectual consequences, and we judge from his last paragraph that he agrees with this view.—EDITOR, NATURE.]

Science and Education at South Kensington.[1]

By T. LL. HUMBERSTONE.

A LARGE part of the area shown in the accompanying photograph was at one time Brompton Park, a fine estate famous for its snipe-shooting and for its mild and salubrious air. In 1675 the park became a market-garden, the first of its kind in England. A short distance eastwards was Knightsbridge, an outlying hamlet of London, the scene of frequent skirmishes during the Civil War. Cromwell's association with the district—there is a tradition that he lived near what is now Queen's Gate—is preserved in the name Cromwell Road. Knightsbridge and Brompton maintained their sequestered character until comparatively recent times. It is recorded that until the middle of the nineteenth century, which must be well within the memory of the oldest inhabitant, people started from Hyde Park Corner at regular intervals in bands for mutual protection, and a bell was rung to warn pedestrians when the party was about to set out. Thus the effective history of the district for our purpose begins in 1851, when the great International Exhibition was opened in Hyde Park. Its initiation and success were largely due to the Prince Consort, and appropriately, therefore, the estate, which was purchased for the modest sum of 150,000*l.* from the profits of the Exhibition, is dominated on the northern and higher side by the Albert Memorial in Kensington Gardens and by the Royal Albert Hall. Would it be possible to find, in the whole educational history of the country, an example of money spent to greater advantage for the promotion of science and art? Sites have been provided for a splendid group of educational and public buildings and in addition a considerable annual income is received which is devoted to scientific purposes. The Exhibition of 1851 justified the hopes of its founders. It was to be for the nineteenth century

[1] It is fitting that NATURE should take advantage of the method of obtaining "bird's-eye" views by means of aerial photography. Arrangements have been made for a short series of articles dealing with certain London areas of scientific interest illustrated by such photographs. The first of these, on South Kensington, is here printed. This will be followed by an article on Bloomsbury by the same contributor.

what the tournament had been in mediæval times—a challenge to every land, "not to the brightest dames and bravest lances as of yore," but to its best produce and happiest device "for the promotion of universal happiness and brotherhood." Happy days! Never perhaps was the spirit of the English people more buoyant, hopeful, confident. This was due in part to a growing appreciation of the benefits which science would confer on humanity.

The Albert Hall was designed to carry out the Prince Consort's expressed ideas as forming "a central point of union where men of science and art could meet, where the results of their labours could be communicated and discussed, and where deputies from affiliated societies could occasionally confer with the metropolitan authorities." Public response to the appeal for the Prince Consort's memorial was less generous than was expected. The memorial in Kensington Gardens, which cost 130,000*l.* and took twenty years to complete, absorbed all the free-will offerings, including 50,000*l.* from Parliament, and it was therefore necessary to establish the Albert Hall on a commercial basis with the financial assistance of the 1851 Exhibition Commissioners, and even of the builders. A capital sum of 200,000*l.* was raised and seats were retailed (with a generous tenure of 999 years) for 100*l.* each. The foundation-stone was laid by Queen Victoria in 1867 and the Hall was opened in 1871. Those who, in view of the uses to which the Hall is occasionally put, may feel doubt as to the high ideals of its founders should read the inscription on the frieze, which asserts: "This Hall was erected for the advancement of the arts and sciences and for the works of industry of all nations, in fulfilment of the intentions of Albert, Prince Consort."

Not far south from the Albert Hall is the most beautiful building on the estate, and possibly in the kingdom, the Imperial Institute. This magnificent pile is the permanent memorial of the completion of the first fifty years of Queen Victoria's beneficent reign. Initiated by the Prince of Wales with the co-operation of the Lord Mayor of London, contributions to the fund poured in from all parts of the Empire. By 1892 a capital sum of 413,000*l.* had been obtained, including 236,862*l.* in private donations from Great Britain and 101,550*l.* from India, and a public grant of 20,000*l.* from Canada. Queen Victoria laid the foundation-stone on July 4, 1887. On this occasion the Prince of Wales expressed the hope that the Institute would hereafter exhibit not only the material resources of the Empire, but be "an emblem of that Imperial unity of purpose and action which we believe has gathered strength and reality with every year of your Majesty's reign." Mr. T. E. Collcutt was the architect, and the style is Italian Renaissance, with rich and abundant ornamentation. The central tower, 280 feet high, contains the Alexandra Peal of ten bells, given by an Australian lady.

Alas! the founders of the Imperial Institute gave more thought to raising the necessary capital than to sordid considerations of current income and expenditure. A somewhat fanciful scheme for electing Fellows, who were given certain club facilities and the right to use letters after their names, came to an untimely end. Call a building a white elephant and close its doors may [illegible] of a well-known proverb. [illegible] culties, the Institute sought the protection [illegible] ance of the Government, which adopted the famili[ar] expedient of taking in lodgers. Thus it came abou[t] that the University of London, which during th[e] whole course of its existence had flitted like an em-barrassed shade from one set of Government lodgings to another, including Somerset House, Marlborough House, and Burlington Gardens, obtained possession in 1900 of the larger part of the Imperial Institute for administrative purposes. In the remaining part of the building, the Imperial Institute continues its work of investigation and propaganda. Let us hope that in the near future the University may find its Canaan in Bloomsbury and this monumental building may again be wholly used for the noble purposes, sealed and sanctified by the War, for which it was originally founded; thus may Queen Victoria's earnest prayer at its inauguration in 1893 be fulfilled that the Institute might "never cease to flourish as a lasting emblem of the unity and loyalty of the Empire."

Reverting to the history of the Commissioners' estate, we find that at an early stage a large piece of ground, 12 acres in extent, was sold to the Government for the purposes of the Science and Art Department and its colleges and museums. This Department, originally founded in 1853 as a branch of the Board of Trade, became a few years later a distinct department of the Privy Council. It was moved westward from its quarters in Marlborough House in 1857 and drew up a programme of educational and scientific work which made "South Kensington" famous throughout the civilised world. The mere catalogue of the institutions which the Department administered is sufficiently impressive, including the South Kensington (now the Victoria and Albert) Museum, the Science Museum, the Science Library, the Royal College of Science, the Royal School of Mines, and the Royal College of Art. The Royal College of Science and Royal School of Mines claim descent from the Government "School of Mines and of Science applied to the Arts," established in Jermyn Street in 1851, and from the Royal College of Chemistry, originally established in Oxford Street, which combined with the School of Mines in 1853. The various departments were transferred to South Kensington between 1872 and 1880 to the old building in Exhibition Road, an early and beautiful example of building in terra-cotta. In 1905 the new chemical and physical laboratories, designed by Sir Aston Webb, were opened in the Imperial Institute Road, and, at about the same time, the new Victoria and Albert Museum, built to the designs of the same architect. The work of the Science and Art Department as a separate department came to an end under the Board of Education Act of 1899. It must be admitted that its adventures into the domain of secondary education were less happily inspired, and that there was need for co-ordination between secondary and technical education. In its day and generation, however, the Department did a great work, from which the impartial historian of national education will not withhold grateful appreciation and the historian of the late War may trace some of the silver threads of victory.

South [illegible] closely associated with the [illegible] scientific education, but [illegible] that history. A permanent memorial there to the technical education movement of the seventies and eighties is the City and Guilds of London Institute for the Advancement of Technical Education. The Institute was formed in 1878 by the Livery Companies of the City of London, one of its principal objects being the establishment of the Central Technical College to supply higher technical education to productive industry. It was designed originally as the coping-stone of a system of technical schools, and particularly for the training of technical teachers. The foundation-stone of the College was laid by the Prince of Wales in 1881, and the building was completed three years later. Its work is now confined to engineering education, and it is one of the largest and best-equipped schools for this subject in the country.

The next important movement, which had for its object the development of teaching and research in applied science, culminated in 1907 in the establishment of the Imperial College of Science and Technology, to which a Royal Charter was granted. The Board of Education transferred to the new governing body of the Imperial College the control of the Royal College of Science and the Royal School of Mines; and the Central Technical College, renamed the City and Guilds (Engineering) College, was also brought into the scheme of common administration. Remarkable progress has since been made in developing the resources of the colleges for teaching and research. A new building has been erected for the Royal School of Mines, and an extension (provided by the Goldsmiths' Company) of the City and Guilds College and others for botany, plant physiology and pathology, and chemical technology, while the social needs of the students have been met by the provision of a special building for the Imperial College Union.

The foregoing list by no means exhausts the buildings at South Kensington. The Natural History Museum (a branch of the British Museum) is in grey terra-cotta, built to the designs of Alfred Waterhouse, and was finished in 1880. It is both a museum and a centre for natural history study and research. The Royal College of Music, a less austere enterprise, was built by Sir Arthur Blomfield and opened in 1894; and the Royal School of Art Needlework and the headquarters of the Royal Geographical Society in Kensington Gore must also be mentioned.

Some final reflections. First and most obvious, the available space at South Kensington is now practically exhausted. Almost the only science which has not been practised at South Kensington is town planning, and there can be no doubt that the area might have been planned more economically. Much still remains to be done in providing new departments of pure and applied science. Under no possible reorganisation of higher education in the metropolis can South Kensington cease to be a most important centre for education and research in science and art. It has great resources in traditions, in men, in materials; and if, like Oxford, it is already the home of some lost causes, it has a marvellous power of adapting itself to new conditions.

Dark Nebulæ.[1]

By Prof. H. N. RUSSELL, Mount Wilson Observatory.

IT is now generally believed that many of the dark markings in the Milky Way, and dark starless regions in the sky, are produced by the interposition of huge obscuring clouds between us and the more remote stars. A long list of such dark markings has been given by Barnard,[2] who has done more than anyone else to point out their importance and probable nature. In some cases, as in the Pleiades, Orion, and Ophiuchus, these "regions of obscuration" merge into faintly luminous nebulosity in the vicinity of certain stars, in such a way that there can be no doubt that they lie near these stars in space.

It thus appears that the obscuring masses or dark nebulæ in Ophiuchus and Scorpius are at a distance of 100 to 150 parsecs, those in Taurus at probably about the same distance, and those in Orion some 200 parsecs from us, while the dimensions of the individual clouds are themselves measured in parsecs.

The occurrence of these three great regions of obscuration within a distance which is so small compared with that of the galactic clouds indicates that such objects are probably of great cosmical temperature.

These dark nebulæ usually appear to be quite opaque. In some cases the stars can be seen faintly through them, apparently without much change in colour; but in some examples[3] stars imbedded in dense luminous nebulosity are abnormally red.

Of the various forms in which matter may be distributed in space, by far the most efficient in producing obscuration is fine dust, since this has the greatest superficial area per unit of mass. In a cloud composed of spherical particles of radius r and density ρ, distributed at random so that the average quantity of matter per unit volume is d, the extinction of a beam of light in passing through this cloud will be e stellar magnitudes per unit of distance, where $e = 0{\cdot}814\, qd/\rho r$. The numerical factor is independent of the physical units which are employed. The factor q is introduced to take account of the complications which occur when the size of the particle becomes comparable with the wave-lengths of light.[4] For particles more than two or three wave-lengths in diameter q is sensibly equal to unity. For smaller particles it increases and is a maximum, 2·56, when the circumference of the particle is 1·12 times the wave-length. It then rapidly diminishes and becomes nearly equal to $14/3 \times (2\pi r/\lambda)$ for particles of less than half this diameter.[5] The ratio

q/r is a maximum, 2·42, when the circumference equals the wave-length.

For clouds of the same mean density d the opacity reaches a sharp maximum when the particles are of this size. At the same time the absorption changes from the non-selective type to the selective type, varying as λ^{-4}. For visual light the maximum opacity occurs when the radius is 0·086 μ. A cloud of particles of this size, and of the density of rock (2·7), will exert an absorption of one magnitude if it contains only 1/86 of a milligram of matter per square centimetre of cross-section, regardless of its thickness. If the particles are of half this size, or smaller, the selective absorption is almost as complete as for a gas, but may be nearly 100 million times as great.

Obscuration of light in space, therefore, whether general or selective with respect to wave-length, will be produced mainly by dust particles a few millionths of an inch in diameter, unless such particles form a negligible proportion by weight of the obscuring cloud.

It is just these particles, however, which will be most influenced by the pressure of the radiation of the stars. Calculations from more accurate data confirm Schwarzschild's conclusion that for a particle of the optimum size and the density of water, the repulsive force of the sun's radiation is about ten times the gravitational attraction, and also show that for stars of the same brightness, but other spectral types, the radiation pressure will be about two-thirds as great for Class M and increase for the whiter stars, till for Class B it is fully ten times as great as for solar stars.

Dwarf stars will scarcely repel dust at all, but giant stars, and especially the very luminous one of Class B, will repel it very powerfully. Only the coarser particles can come near such a star—the finer ones being driven away. This selective removal, from the vicinity of bright stars, of the particles which are most efficient in cloud formation, may explain the fact that the luminous portions of these dark nebulæ, though centred upon stars, do not brighten up in their immediate neighbourhood so much as might have been anticipated.

The finest dust must continue to be repelled by the stars, whatever their distance. It may congregate to some degree in interstellar regions, where the repulsive forces from stars on opposite sides are nearly equal, but it can be in no true equilibrium there, and must escape ultimately to an indefinitely great distance.

Some force, however, operates to hold these dark clouds together, for their outlines are often sharp. This is probably the gravitational attraction of the cloud itself.

Taking a spherical cloud as an example we find that, if its mass is M times that of the sun, and its radius R parsecs, the velocity of escape at the surface is $0{\cdot}092\, M^{\frac{1}{2}} R^{-\frac{1}{2}}$ km./sec. The internal velocity of the nebular material is known only in the case of the Orion nebula, where the luminous gas shows irregular variations in radial velocity from point to point, amounting to about 5 km./sec. on each side of the mean.[6]

For a nebula 1 parsec in diameter (which may be taken as a rough representation of the small black, almost round spot about 15′ in diameter, discovered by Barnard in Ophiuchus) the mass must be 60 times that of the sun, if the escape velocity is to be 1 km./sec.

If all this matter were in the form of particles of rock of the optimum size, the extinction for light passing centrally through the cloud would be 2000 magnitudes. An extinction of 10 magnitudes (quite sufficient for opacity) would be produced if the radii of the particles were 72 μ.

Though these numerical values are largely conjectural, it appears probable that the aggregate mass contained in one of these great obscuring clouds must be very considerable—probably sufficient to form hundreds of stars—and that a sensible fraction of the whole mass must be in the form of dust less than 0·1 mm. in diameter.

It can easily be shown that any dust cloud which is impervious to light must also be impervious to particles such as those of which it is composed (and to free-moving electrons as well) in the sense that such a particle could not traverse the cloud without a practical certainty of collision. These collisions may account for the existence of dust within the clouds, even if it was not a primitive constituent.

The transition from these dark nebulæ to luminous nebulæ in the vicinity of the stars appears to occur in two ways. The first is by simple reflection of the light of the stars: this appears to occur in the nebulosity surrounding the Pleiades, the star ρ Ophiuchi, and probably in many other cases. The second is by the excitation of gaseous emission, as in the Great Nebula of Orion, which is connected with one of the greatest known regions of obscuration and itself shows signs that obscuring masses lie in front of it.

Both theoretical considerations, as suggested by the writer[7] and the facts of observation collected by Hubble,[8] indicate that the luminosity of gaseous nebulæ is probably due to excitation of the individual atoms by radiations of some sort (aethereal or corpuscular) emanating from neighbouring stars of very high temperature. In the Orion nebula the stars of the Trapezium (θ Orionis) appear to be the source of excitation.

There is no reason to believe that the luminous gas forms the whole, or even any large part, of the matter present within the region—only that it is selectively sensitive to the incident excitation, and therefore gives out most of the light, just as the gases (carbon compounds and nitrogen) do in the coma and tail of a comet.

If the turbulent motions of the various parts of this nebula are of the same order of magnitude in the other two co-ordinates as in the radial direction, they must correspond to an average proper motion of 1·5 astronomical units per year, or about 0″·8 per century (with Kapteyn's parallax of 0″·0055). In a million years this would carry a nebulous wisp through 2°, which is more than the whole extent of the nebula.

It appears probable, therefore, that the aspect of the Orion nebula was entirely different a million years ago from what it is now, as regards its details. There is no reason, however, to suppose that the nebula was not there. We may rather imagine that wisps and clouds of dust, carrying gas with them, are slowly drifting about. Some of them pass through the field of excita-

tion due to the radiations from the Trapezium stars, and, when in this field, the gas is seen shining—faintly near its outskirts, and without excitation of the nebular lines; more strongly, and with the nebular lines, near the middle.

According to unpublished investigations by Hubble, it appears probable that the absorbing clouds in Orion, not far from the nebula, weaken the light of stars behind them by at least ten magnitudes. The exciting radiations probably penetrate to a relatively small depth into the mass and, even if they went deeper, little of the excited light could get out again. The Orion nebula, on this hypothesis, may be regarded almost as a superficial fluorescence of the gaseous portion of this vast dark cloud, in the limited region where it is stimulated by the influence of the exciting stars.

The Corrosion of Ferrous Metals.

THE fact that iron readily perishes when exposed to the forces of Nature must have been observed by man practically as long as the metal itself has been recognised. But it is only comparatively recently that the problem of the preservation of iron from corrosion has developed into one of such stupendous economic importance as at the present day. Sir Robert Hadfield estimates the wastage of the world's steel on account of rust alone to reach some 29 million tons for the year 1920. This, at an average figure of 20*l.* per ton, represents a loss to the community of at least 580,000,000*l.* One interesting feature of this calculation is that the annual increase in the world's total stock of iron and steel is only some 30 per cent. of the annual production, the remaining 70 per cent. being absorbed in replacing wastage consequent upon fair wear and tear and upon corrosion.

In a paper read before the North-East Coast Institution of Engineers and Shipbuilders in April last, Mr. A. Pickworth most opportunely directs the attention of marine engineers to this aspect of the subject. It is pointed out that the repairs necessary to counteract the ravages of rusting during ten years' service in the case of a single battleship have, for structural work alone, been known to cost some 150,000*l.* Any one, therefore, who can assist in combating this destructive plague to iron and steel merits the gratitude of the community.

It is now well recognised that, in addition to air, the presence of liquid water is essential to corrosion. Rise of temperature accentuates the evil, the rate of oxidation of iron immersed in water at 80° C. being more than seven times as great as that at 0° C. It is easy, therefore, to offer an explanation, as Mr. Pickworth points out, for the fact that corrosion assumes more serious proportions in the vicinity of boiler-room tanks in steamers than elsewhere. The tanks, whether used for ballast or feedwaters, are alternately filled and more or less completely emptied, but are rarely if ever, thoroughly dry, for obvious reasons. The residual moisture, coupled with unequal distribution of waste heat from the boilers, and erratic cooling from the floor and shell plating in contact with the sea under the vessel, results in rapid corrosion. The steel work of the bunkers of a vessel frequently requires patching or renewing on account of corrosion. This is particularly the case with pocket bunkers at the sides of the boilers or 'tween-deck bunkers above the boilers. Not only does the heat from the boilers and the moisture in the coal tend to produce a corrosive atmosphere, but the abrasive action of the coal as it enters from the shoots and while it is settling as the lower layers are worked out all tend to accentuate the destruction of the metal. In practice it is found that the lower parts of the bunkers are the most seriously affected, and this is attributed to the accumulation of a mixture of small coal and mud which is rarely removed except at special surveys. Although in exceptional cases the outside surfaces of the shell plating of a ship may be seriously pitted and corroded, as, for example, when the vessel has been lying in very foul waters, the general rule appears to be for the wastage to be greater on the inside surfaces. This is due, in the main, to the extra cleaning and general attention received by the outside surfaces. Special care should be paid to those portions of the inside shell immediately under the sidelights, for the constant trickling of rain or water of condensation from the glass induces most serious corrosion, resulting at times in actual perforation of the plating.

As might be expected, the most serious external corrosion of the shell plating occurs in the neighbourhood of the wind and water line, the metal being alternately drenched and exposed to air. The surface water also is in motion relatively to the plates, and this tends to stimulate corrosion. One interesting point deserving of consideration is the fact that the external portions of a vessel above the water-line receive deposits of sodium chloride in consequence of the evaporation of sea spray. Owing to the hygroscopic character of the deposit, as well as to its chemical activity, corrosion is readily induced thereby.

It is difficult to obtain trustworthy comparative data on the relative efficiencies of different methods of avoiding corrosion. Early man frequently surrounded his iron with copper or bronze, so that his implements might possess the strength of the former combined with the incorrodibility of the latter metal. Modern developments of this process are galvanising, tinning, electroplating, and the like. The Bower-Barff process consists in coating the iron or steel with magnetic oxide, which is an excellent protection so long as it remains unbroken. The metal is cleaned, heated in a closed chamber by means of producer gas, and finally oxidised in a current of superheated steam for a couple of hours. If, however, the resulting coat of oxide should crack or chip off at any point, the layer of unprotected metal thereby exposed is rapidly attacked. The oxide functions as cathode and the metal as anode, so that deep pitting ensues. Mr. Pickworth mentions that a certain shipowner, relying on the protective action of mill scale, gave instructions for a ship to be built, the shell plates of which were to retain their mill scale as completely as possible. For a time all went well on service, but suddenly the vessel developed leaks and was almost lost. Upon docking it was found that many of the plates had been deeply pitted and even perforated in a number of places where the mill scale had been destroyed either during construction or through

abrasion in service. It is now usual to remove scale by pickling, by weathering, or by some other suitable method, prior to painting, in order to avoid such disaster.

A second method of combating corrosion consists in alloying the iron with some other element that will render it incorrodible. This is the principle underlying the so-called "stainless steel," which contains some 12 to 14 per cent. of chromium, and is remarkably resistant to neutral corrosion, although acids dissolve it with ease. Unfortunately the cost is high, but once that difficulty is surmounted, a vast future lies in store for stainless metals. To realise this it is not essential that the price should fall to that of an ordinary carbon steel. To the writer's own knowledge the cost of painting the steel work in a certain large works recently averaged nearly 5*l*. per ton of steel painted. Assuming the paint will not require renewal within five years, the average annual cost is still 1*l*. per ton of steel. A firm could thus clearly afford to pay considerably extra in initial outlay if by so doing a really incorrodible structure could be obtained which would not require subsequent periodic treatment.

Yet a third method of reducing wastage by corrosion has been investigated, namely, the removal of the active corroding agent, dissolved oxygen, from waters in contact with the metal. The various means of doing this are discussed by Mr. Frank N. Speller[1] in an interesting paper entitled "Control of Corrosion by Deactivation of Water." The method has its limitations, but for hot-water heating systems it would appear to be particularly suitable. The oxygen may be removed either chemically or by purely physical means. A satisfactory plant [illegible] which the water [illegible] activator," which is a tank filled [illegible] of expanded steel lathing. The steel rusts and thus deoxygenates the water, which then passes on to the heating system and is now non-corrosive. The principle is simple enough, but in practice it is necessary to pay great attention to the manner in which the deactivator is charged. Miscellaneous steel turnings usually rust together into a tight mass which offers serious resistance to the flow of the water. In a later form of deactivator installed in Boston in 1917 a filter was provided in order to remove all suspended hydroxide of iron.

Many types of mechanical de-aerators have been designed. The apparatus made by "Balke" in Germany appears to have given satisfactory results. The water at ordinary temperature is sprayed into a chamber carrying a 90 per cent. vacuum, and the released gases are pumped off into a condenser. The efficiency of mechanical de-aerators is of course limited by the solubility of the gases, the temperature, and the power of the vacuum. Normally, therefore, there will always remain a certain amount of unextracted oxygen which may be sufficient to induce gradually serious corrosion in the plant. On the other hand, chemical processes can remove all the dissolved oxygen under favourable conditions. Speller therefore suggests that where very large volumes of water require de-aeration, an economical type of apparatus would be one in which the bulk of the dissolved oxygen is first removed by some simple form of mechanical de-aerator, and the residual oxygen, say the last 5-10 per cent., by chemical treatment.

Obituary.

Ernest Solvay.

On May 26 last, at the ripe age of eighty-five, there passed away, at his residence in Brussels, in the person of Ernest Solvay, one of the world's greatest industrial chemists. To Nicolas Leblanc belongs the credit of inventing the first successful process for manufacturing artificial soda; but it remained for the brothers Ernest and Alfred Solvay to provide the world with a pure and cheap product.

Ernest Solvay was born at Rebecq in Brabant, Belgium, on April 16, 1838. He was the son of Alexandre Solvay, a quarry proprietor and salt refiner. In 1838 two English chemists, Harrison Gray Dyar and John Hemming, patented a process for producing carbonate of soda by acting upon sodium chloride with ammonium bicarbonate and producing sodium bicarbonate and ammonium chloride. The sodium bicarbonate upon calcination yielded soda ash, and the ammonium chloride was decomposed by lime to free the ammonia for re-use. The patentees themselves, and several well-known chemists, erected works to manufacture by this process, but all proved failures, principally on account of the high loss of ammonia. The young Belgian chemist, Ernest Solvay, at the age of twenty-four, was attracted by the process, and, after two years of study and experiment, he devised such modifications as appeared to him to ensure its practicability, and embodied them in a patent in 1863.

Calling to his aid his brother Alfred, who had been trained for a commercial career at Antwerp and at Hull, they erected works at Couillet, near Brussels, as Solvay et Cie, with a capital of 5440*l*. With the starting of these works in 1865 the brothers met with most of the troubles and disasters that had daunted the earlier experimenters. Their experience is perhaps best described in Ernest Solvay's own words:

"With the starting of the works in 1865 began the everlasting struggle, the incessant need for improvements in apparatus, and the series of accidents inseparable from every new industry. This was the hill of Calvary which we had to climb, and its rough road might perhaps have stopped me if I had not been sustained by my confidence of success in the task that had to be accomplished, and above all by that devoted helper, my brother Alfred."

In the following year (1866) the works were producing only 1½ tons of soda ash per day, but by 1869 the process had proved so successful that the works were doubled in size. During these fateful four years, Solvay had encountered all the difficulties that had baffled his predecessors, both technical and financial; but, by his application of wonderful scientific skill and his tireless attention to work, he succeeded in evolving

a remunerative method of manufacture. It was, however, far from perfect, and for the next fifty years Solvay continued to work at it, sparing neither time nor money to make it approach the ideal. At the time of his death, there are very few methods of manufacture that have so nearly reached the ideal as the Ammonia Soda process.

In 1873 Solvay granted a licence to John Brunner and Ludwig Mond to work the process in England, and Brunner, Mond and Co. started works at Winnington, Northwich, in that year. From this business connexion there sprang up a friendship among the three men that lasted as long as their lives, and it is difficult to decide whether Solvay or Mond effected thereafter the greater number of improvements in the process and apparatus.

In the same year Solvay and Co. erected their large works at Dombasle near Nancy, introducing all such improvements in plant as experience at Couillet had shown to be advisable.

From this time onwards to 1914 few years passed without some new works being erected to carry on the manufacture; in the United States in 1881, in Russia in 1881, in Germany and Austria in 1885, and later in Hungary, Spain, Italy, and Canada, until in 1914 there were scattered throughout the world twenty-three separate works engaged in the Solvay Ammonia Soda process, which were capable of producing nearly 2,000,000 tons of soda ash per year.

With the growth of the Ammonia Soda process, the production of alkali by the Leblanc method gradually declined, until it reached the point where it had to depend upon its chlorine products for its continued survival, and of late years even this monopoly has been seriously challenged by the electrolytic processes. In 1863 the world's production of soda, by the Leblanc process, was 300,000 tons a year. In 1913, the total production amounted to nearly 3,000,000 tons, of which almost two-thirds was made by the Solvay process, while the sale price had dropped to one-quarter. The essential raw materials for the Solvay process are salt, limestone, coke, coal, and ammonia, and in selecting sites for new works, Solvay was ever careful to choose them as near as possible to the source of supply of some of these.

In seeking for a cheap and plentiful supply of ammonia, Solvay was led to study the production of coke, and eventually, in conjunction with Mr. Semet-Solvay, he designed a bye-product coke oven which yielded ammonia through the scrubbing of the gas before its combustion for heating purposes. Many thousands of these Semet-Solvay ovens have been built in Belgium, France, England, Germany, the United States, Italy, and Japan, and in 1913 they were producing about 10 million tons of coke a year.

In the midst of his immense industrial activities Solvay was ever mindful of the welfare of his employees. Working a process that must of necessity be continuous, he was one of the first to reduce the hours of labour from 12 to 8-hour shifts. He insured his workmen against accidents, instituted savings-banks and retiring allowances, provided them with medical attention, built houses for them, and remitted the rent in cases of long service or distress, made free grants of land for culture, built schools and gave scholarships, and made grants in aid of higher education both in Belgium and abroad.

On the occasion of the company's fiftieth anniversary, a number of grants were made, among which were: 260,000 francs to the Université du Travail, Charleroi, 500,000 francs to provide prizes every fourth year for work on such contagious diseases as the poor are specially liable to suffer from, 500,000 francs to the University of Paris towards the Institute of Applied Chemistry, 500,000 francs to the University of Nancy to complete the Electrical Institute and found a chair of electro-chemistry. In addition, their workpeople received substantial concessions and bonuses. Ernest Solvay's sympathies and interests were not confined to his own workpeople, for he was absorbingly interested in the intellectual and social advancement of mankind in general. He published not only many treatises on these subjects, but also from his immense wealth financed or created numerous institutions for their study; *e.g.* the Solvay Society of Brussels and institutes of chemistry, physics, physiology, and sociology. In order to encourage the development of chemical and physical science, by providing funds for research workers and by holding conferences, he also inaugurated the Solvay International Institutes of Chemistry and of Physics, and endowed each with a capital of 1,000,000 francs.

During the war, Solvay elected to remain in Brussels, in order that he might alleviate the suffering which he foresaw would be the lot of the poor. He devoted his energies and his fortune to this object throughout the whole of the German occupation, and the city will never forget his beneficence. Upon his return to the capital, King Albert personally expressed his thanks to him and created him a Minister of State. He was also the recipient of many other honours. He was a Grand Commander of the Order of Leopold, a Chevalier of the Legion of Honour, a Doctor of the University of Brussels, an honorary member of the Royal Institution of London, and of the German, French, American, and Dutch Chemical Societies, and a corresponding member of the French Academy of Sciences.

At the celebration of the fiftieth anniversary of the formation of his company, he was presented by Prof. Haller in the name of the French Institute with the gold Lavoisier Medal, and by Prof. Appell with the medal of the University of Paris.

In private life Ernest Solvay's tastes were simple, and he was ever happiest in his own family circle. He attracted to his side many men of exceptional ability and formed lasting friendships. By nature he was generally optimistic, and he had a very keen sense of humour. He was an ardent mountaineer, and regularly his summer holidays were spent among the Alps. He could climb vigorously at the age of seventy-five, and abandoned the sport only a few years prior to his death.

JOHN I. WATTS.

THE HON. V. A. H. H. ONSLOW.

HUIA ONSLOW, son of the fourth Earl of Onslow, was born in New Zealand in 1890, where his father was Governor-General. Educated at Eton and Trinity College, Cambridge, he met with a calamitous accident at the close of his University career; an injury received in diving left him paralysed below the waist, with no

hope of recovery. Though broken in body, his courage never left him, and with splendid bravery he devoted to scientific work such as remained to him of life. Special facilities for research led him to settle in Cambridge, where he turned one of the rooms of his house into a laboratory into which his couch could be wheeled. Here he became a pioneer in establishing contact between the two growing branches of biology—biochemistry and genetics. Genetical research had recently demonstrated the existence of two distinct kinds of white in the coat of certain animals—one dominant and the other recessive to colour. It had been surmised that in the former case the coat carried something which inhibited the production of colour, and that in the latter either the chromogen was absent, or else some substance which activated it. Onslow's chemical work took the question out of the realm of speculation, and placed it on a solid ground of fact—a notable contribution, which will be found in the Proc. Roy. Soc., 1915. At the same time he was carrying out extensive breeding-experiments with mice and rabbits, both at Cambridge and Pyrford, which helped materially in laying the foundation of a sound genetical knowledge of coat-colour. But it was the biochemical side that attracted him most, for he realised that the geneticist could not go very deep without the help of the chemist. He wished to approach the problem from both sides, and, with this end in view, started breeding-experiments with moths, concerning himself chiefly with melanic forms as likely to be of service for the chemical side of the inquiry. The results were published in a series of papers on the "Inheritance of Wing Colour in Lepidoptera," which appeared in the *Journal of Genetics*, 1919–21. Meanwhile, he became interested in the brilliant iridescent colours exhibited by many insects, and on this subject contributed last year an important paper to the Philosophical Transactions. Full of fresh and suggestive observations, it is pervaded by a critical power of thinking, and a knowledge of the physics involved, which must make it a landmark for future investigators of an intricate and fascinating series of problems.

And all this from an invalid couch, full of suffering, and stricken beyond hope of recovery. But fine as is the achievement, finer still was the way in which it was won. With life seemingly wrecked at the very start, his spirit rose above the physical crash, bravely accepted what had to be, and created out of the ruins a fresh life which was the wonder of those who knew him. What he did, and what he was, will assure him of that immortality that lives upon the lips of men; and with that we may

"Leave him still loftier than the world suspects,
Living and dying."

DR. A. R. WILLIS.

MANY students will regret the death of Dr. Ambrose Robinson Willis, at the age of seventy-two, on May 23 last. From 1872, when he entered the Royal School of Mines as a Royal Exhibitioner, until 1911, when he retired owing to ill-health from the Imperial College of Science and Technology, he had been continuously associated with the South Kensington institution.

In 1875 he obtained the A.R.S.M. in mining, metallurgy, and geology, the Duke of Cornwall's scholarship, the Murchison medal and prize, and the Edward Forbes medal and prize. The wide range of his studies is indicated by the facts that in 1876 he obtained first-class honours in zoology and chemistry at the London B.Sc.; in 1879, the London B.A.; in 1881 the M.A.; and in 1883 the D.Sc. in mathematical physics. He was made assistant-professor in mathematics and mechanics at the Royal College of Science in 1884, being associated first with Goodeve and later with Perry. He also acted as examiner in mathematics for the Universities of London and Manchester.

It was as an instructor that Dr. Willis will be remembered, not only by old students of South Kensington, but by an enormously wider circle, in his capacity as an examiner in mathematics to the Science and Art Department and afterwards to the Board of Education. With his fellow-examiners Twisden and Wrigley, he exercised a tremendous influence for many years on students of mathematics and mechanics in all parts of the country. It was no small task virtually to direct the studies of an army of men, the majority with little time to spare from manual work, without means and often without a teacher, and whose only inspiration and incentive came from the desire to pass the various Board of Education examinations. That the duty was ably and wisely carried out will be readily admitted, and by none more than by those who, entering the Royal College of Science as exhibitioners or scholars, came into personal contact with the man who had done so much to direct their earlier studies.

Times have changed, and it is not so easy now to bring home the realisation of what it meant to men whose training had been on these lines, to attend Dr. Willis's lectures and listen to his extraordinarily clear, orderly, and inspiring exposition of mathematics. In his prime few can have equalled him in this respect—he radiated enthusiasm as he developed the argument, and his triumph as the full power of the attack made itself felt was delightful to see. Many hundreds of science teachers will still remember wistfully Dr. Willis's carefully prepared lectures in the short "summer courses" for teachers, which were arranged each year at South Kensington by the Board of Education.

Dr. Willis took a real personal interest in his students and possessed the faculty of making the shyest of men feel quite at ease with him. Many of his students can testify to innumerable kindnesses unobtrusively performed, and to his quiet support of any movement which would activate the social side of the College's work. His whole-hearted thoroughness, wide experience, geniality, North-country shrewdness, and sound common sense were greatly appreciated in university circles. His retirement in 1911 was made the occasion of a demonstration of affection and good-will from hundreds of old students, and he then voiced the great satisfaction that he felt to see so many of his old students playing prominent parts in the scientific world, not least in the development of aeronautics.

Current Topics and Events.

THE portrait medallion of Sir Norman Lockyer, by Sir Hamo Thornycroft, which is to be erected at the Norman Lockyer Observatory, Salcombe Hill, Sidmouth, will be unveiled by Sir Frank Dyson, Astronomer Royal, on Saturday, July 22. Lt.-Col. F. K. McClean, a generous benefactor to the observatory, will present the medallion on behalf of the subscribers, and it will be received by Sir Richard Gregory, chairman of the council. The observatory was erected in 1912 upon a plateau 550 feet above sea level, and is unique of its kin in Great Britain, being vested in a registered corporation which possesses the whole of the property and controls the operations. It was founded by Sir Norman Lockyer, and was formerly called the Hill Observatory, but since that distinguished astronomer's death the name has been changed to the Norman Lockyer Observatory in honour to his memory. The director is Major W. J. S. Lockyer, and there is a research committee consisting of Sir Frank Dyson, Prof. A. S. Eddington, Prof. A. Fowler and Prof. H. H. Turner. The observatory possesses an equipment of the first rank for spectroscopic work, and photographs of stellar spectra taken in it are being used for the determination of the parallaxes of stars. The method used was first worked out at the Mount Wilson Observatory and it represents one of the most remarkable developments of astrophysics ever achieved. The gifts of Sir Norman and Lady Lockyer, Lt.-Col. McClean, Mr. Robert Mond, Capt. W. N. McClean and others, together with subscriptions of members, have been sufficient to establish and maintain the observatory hitherto, but additional funds will be required if the work is to be carried on efficiently. In the United States, generous donors to astronomy seem to be forthcoming whenever they are needed, with the result that the chief advances of astronomical science are being made there. The Norman Lockyer Observatory, on account of the elasticity of its constitution, offers similar benefactors in this country an excellent opportunity for emulating the example afforded by America, and we trust that one or more of them will provide the means to continue and extend the work to which a few devoted people have already contributed their full share.

UNUSUALLY heavy gales for the season of the year have occurred over England during the early part of July, especially during the night of July 5-6, and the tempestuous winds were accompanied by torrential rains. On the south-east coast of England the wind attained the velocity of about 60 miles an hour, and at Kew Observatory the velocity registered 53 miles an hour. London experienced considerable interruption to telephone communication, and in the open country much damage was done to the fruit crops. A renewal of the stormy conditions occurred on July 8-9.

OWING to the early breaking of the monsoon the attempt on Mount Everest planned for June 3 had to be abandoned. The *Times* announces that the members of the expedition are now returning to India. Col. Strutt, Dr. Longstaff, and Mr. Finch have already sailed for England. Mount Everest thus remains unconquered, at any rate for the present, the greatest altitude that was reached being 27,300 feet, or about 1700 feet below the summit. Col. Strutt believes that given favourable weather a future expedition should be able to reach the summit.

THE *Quest* with the Shackleton-Rowett expedition has left Cape Town and arrived at Simonstown on July 7. After a few days there, according to the *Times*, she sails for home via South Trinidad and Rio de Janeiro. It is proposed to spend two days at South Trinidad, the uninhabited volcanic island in the South Atlantic. The island has been frequently visited, notably by the *Discovery* in 1901 and the *Valhalla* in 1905. At an earlier date it obtained fame by reason of several searches for buried treasure. The *Quest* may be expected at Plymouth about September 21.

ACCORDING to the *Meteorological Magazine* of June, a new record height of 10,518 metres (34,500 feet) was attained by J. A. McCready in an aeroplane flight at Dayton on a Lepère machine, with a 400-h.p. Liberty engine, during September 1921. The previous record, by Major Schroeder, has been reduced by the authorities responsible for the official figures from 36,000 feet to 33,114 feet.

IT is reported in the *Times* that Captain Amundsen, aboard the *Maud*, left Nome, Alaska, for Cape Barrow, on June 30. Early in August he proposes to make his flight across the Pole, either to Greenland or, more likely, to Spitsbergen. The route to Spitsbergen is the longer of the two, but Capt. Amundsen believes he can make the journey in eighteen hours. His aeroplane has been tested in a thirty-two hours flight. The Norwegian Government is taking steps to afford all possible assistance to Capt Amundsen in the event of his reaching Spitsbergen or Bear Island.

INVITATIONS to serve on the Committee on Intellectual Co-operation of the League of Nations have been accepted by Mr. D. N Banerji, Prof. Henri Bergson, Mlle. Bonnevie, Prof. A. de Castro, Mme. Curie, M. J. Destrée, Prof A. Einstein, Prof. G. Gilbert Murray, M. G. de Reynold, Prof. F. Ruffini, M. L. de Torres Quevedo, and Dr. G. E. Hale. The committee, which will be entrusted with the examination of international questions regarding intellectual co-operation, will hold its first meeting in Geneva on August 1.

SINCE the eruption of 1906, Vesuvius has remained inactive on the whole until the early part of the present year. On February 26 the main cone, which had grown since 1906 to a height of about 230 feet, collapsed during an eruption, and shortly afterwards lava issued from several fissures; it has flowed ever since in amounts that are considerable, though not sufficient for it to escape from the crater. Since February a new crater has been formed and has grown with great rapidity. Towards the end of June,

a large fissure appeared in its western side, and from it there came a stream of lava about thirty feet wide. Owing to these recent flows and to the presence of sulphur fumes, it is difficult to reach the floor of the crater. In the *Times* for July 3 are reproduced, however, two photographs taken from within the crater, one of the new cone, and the other of the lava-stream issuing from it and showing very clearly the fluxion-structure of the lava.

MAY and June were both comparatively dry months this year at Greenwich Observatory, the rainfall in May being only 57 per cent. of the 100 year average, while June was 70 per cent. of the 100 year average for the corresponding month. In January, February, and April the rainfall was in excess of the average. In 1921, each of the first six months had a rainfall less than the normal. The total for the first half of the present year is 10·73 in., while in 1921 the total for the same period was only 5·97 in. The 100 year average for the six months is 10·47 in., and for the 35 year average, used by the Meteorological Office, 10·21 in., so that the period from January to June shows an excess on the normal. There was an absolute drought this year from May 26 to June 12, a period of 18 days, the only drought as yet registered in 1922. July bids fair to be a wet month; practically the average rainfall for the month in London fell in the first week.

THE Natural History Museum Staff Association held their summer scientific reunion in the board room of the Museum on July 5. There was a large attendance. Among other interesting exhibits were the following: specimen of the supposed gigantic Gastropod (*Dinocochlea ingens*) from the freshwater sandstones in the Wadhurst Clay, Hastings; the natural cast of a footprint of an Iguanodon from the Wealden Beds, between Bexhill and St. Leonards; opalised Mollusca of Cretaceous age from New South Wales and South Australia; skin with scutes of a stegosaurian dinosaur from the Upper Cretaceous, Alberta, Canada; specimens from the collection of Swiss minerals bequeathed to the Museum by the late Rev. J. M. Gordon; one of the four meteoric stones which fell in the Strathmore district of Perthshire and Forfarshire on December 3, 1917; living specimens of a branchiopod crustacean (*Leptesheria dahalacensis*) hatched from eggs contained in dried mud from Bagdad; ammonites with the operculum preserved and associated fossils from the same bed in the Lias at Charmouth, Dorset; Horse Chestnut seedlings, illustrating three different methods of replacing the bud of the primary shoot; a very rare British orchid (*Orchis hircina*) recently found near Lewes; examples of the remarkably different, smooth and partly rough, skinned fruits borne on the same tree of the Khatta orange, North India; model of Commerson's dolphin (*Cephalorhynchus Commersoni*) from Port Stanley, Falkland Islands; and the model, enlarged 740 diameters, of the itch mite (*Sarcoptes Scabiei*) recently made for the Museum by Miss Grace Edwards. Messrs. R. and J. Beck exhibited their most recent forms of microscope, and Duroglass Ltd. showed examples of their glassware for preserving specimens in spirit and for use in chemical analysis.

AT a meeting of the Royal Society of Edinburgh on June 5, Dr. C. G. Knott, general secretary, gave an account of a correspondence between the Academy of Sciences of Paris and the Royal Society of Edinburgh, in which the Council of the latter Society directed attention to the fact that the "Cable Guide" system which was being accepted as the invention of M. Loth during the late war, was invented by Mr. C. A. Stevenson thirty years ago, and described in the Proceedings of the Royal Society of Edinburgh in 1893. In 1921 M. Loth was awarded an important prize for his valuable work in connexion with naval problems, and the report of Vice-Admiral Fournier, in recommending the award, referred pointedly to the method of the pilot cable for guiding ships by electrical signals into harbours during night or at times of fog. A comparison of this report with Mr. C. A. Stevenson's patent of 1893 showed that the two systems were fundamentally identical. Compared with M. Loth's beautiful devices, made possible in these days by the remarkable developments in methods for detecting electric and magnetic charges, Mr. Stevenson's early methods may appear crude, but that does not invalidate his claim as the originator and the first experimenter along these lines. Not only did he invent the pilot cable, but he was the first to demonstrate practically how it could be used in guiding vessels up estuaries and into harbours by means of electric signals from a sunken cable. It was a simple act of justice that these historical facts should be recognised and due credit given to Mr. Stevenson for his valuable pioneer work. A French translation of the statement prepared by the Council has been sent to the Academy of Sciences with the request that it be published in the *Comptes rendus*.

THE Paris correspondent of the *Times* states that the late Prince of Monaco has bequeathed sums of one million francs each to the Académie des Sciences, the Académie de Médecine, the Institut Océanographique, the Institut de Paléontologie Humaine de Paris, and the Musée Océanographique de Monaco.

THE Council of the Marine Biological Association of the United Kingdom has passed a resolution expressing "their respectful homage to the memory of His Highness the late Albert I., Sovereign Prince of Monaco, and their deep appreciation of the great services rendered by him to the advancement of the Science of the Ocean."

THE undermentioned Fellows of the Geological Society have been nominated as Delegates of the Society to the Brussels Geological Congress, 1922: Dr. J. W. Evans, Prof. E. J. Garwood, and Prof. W. W. Watts.

ACCORDING to the *Electrician* the posts of electrical adviser to the Government of India and chief engineer of the Hydro-Electric Survey of India, at present held by Mr. J. W. Meares, are shortly to be abolished.

LORD COLWYN will open the research laboratories of the Research Association of British Rubber and Tyre Manufacturers at 105-7 Lansdowne Road, Croydon, Surrey, on Wednesday, July 26, at 3 P.M.

THE third report of the departmental Committee on Lighting in Factories and Workshops, just issued, deals mainly with the definition of "adequacy" of lighting, which it has already been recommended should be required by Statute and defined by Order of the Secretary of State for different industrial processes. The Committee considers that much work still remains to be done before the regulation of factory lighting can be established on a basis of definite legal minima for illumination. Ample proof is forthcoming of the relation between lighting and production and safety It is therefore suggested that the chief industries should be invited to assume partial responsibility by sharing in further investigations into the lighting requirements of work in these industries. Meanwhile, as an indication of what is desirable, the Committee furnishes an appendix in which processes in the chief industries are classified as "fine work," requiring 3 foot-candles, and "very fine work," requiring 5 foot-candles. In other appendices values demanded in American codes on industrial lighting are given. It is gratifying to observe that there has already been a substantial improvement in industrial lighting since the Committee commenced its labours, and there is no doubt that the moderate course they recommend in regard to legal minima will meet with general approval.

MESSRS. GALLENKAMP AND CO., referring to the paragraph in NATURE, July 1, p. 19, on the efforts made by the Museums Association to get rectangular glass jars manufactured in this country, remind us that they are prepared to supply such jars. They have been exhibiting samples at the Museums Association Conference at Leicester this week; we understand that they were unable to make these jars when approached by the Association.

THE attention of archæologists may be directed to a lecture delivered by Mr. G B. Gordon at the University Museum, Philadelphia, and published in the *Museum Journal* (vol. xii. No 4), issued by that institution, in which he describes the walls and other antiquities of Constantinople Mr Gordon gives a graphic sketch of the history of the city in relation to the existing remains, and his lecture is illustrated by an admirable series of photographs.

A USEFUL list (No. 432) of publications on agriculture and gardening, including some rare herbals, has just been circulated by Mr. F. Edwards, 83 High Street, Marylebone, W 1. It is obtainable free, upon request, of the publisher.

Our Astronomical Column.

SKJELLERUP'S COMET.—This comet was photographed by Mr. Davidson at Greenwich on June 21 and July 3 The results show that a slight lengthening of the period (previously given as 4·72 years) is needed, and 5·1 years is probably near the truth This is not unfavourable to the suggested identity with Grigg's Comet 1902 II Dividing the interval by 4, 4·96 years is obtained as the mean period since 1902, and 5·1 years is quite within the limit of change that might have been produced by Jupiter-perturbations These would have been considerable early in 1905, and sensible in 1915 The new period is much the same as that of Tempel's Comet, for which the value 5·16 years was found in 1920 This has hitherto been reckoned the second shortest cometary period.

Profs Crawford and Meyer of Berkeley Observatory, California, find the period 5·53 years for Skjellerup's Comet, but this appears to be somewhat too great, judging by recent observations.

PERIODICAL COMETS.—An investigation has recently been completed by Miss J. M. Young, instructor of mathematics at the University of California, "on the causes which have prevented certain periodical comets being redetected on their predicted returns."

She has brought a number of interesting facts together, with regard to Barnard's Comet of 1884 and Denning's Comet of 1881, and concludes that the most probable period for the former is 5·39 years, and for the latter 8·84 years. Neither of the comets alluded to have been redetected since the years of their discovery, but at certain returns the conditions have been very unfavourable. Miss Young concludes that periodic comets often escape observation owing to the fact that they have not been searched for over a sufficiently large extent of the heavens.

It is to be hoped that greater efforts will be made to rediscover some of the numerous comets of short period which have only been observed at one return. Denning's Comet of 1881 is due in 1925, when the conditions may be favourable, but there is considerable uncertainty as to the date of perihelion.

ROCHE'S LIMIT FOR SATELLITES.—It is not always remembered that the limit assigned by Roche as the minimum-distance of a satellite from its primary (depending on the density of the latter, but of the order of 2½ times its radius) takes no account of the force of cohesion in keeping the satellite particles together In the case of bodies of the size of the earth or moon, the disruptive forces would be so large that the force of cohesion might be neglected compared with them; but the case is different when we consider little bodies like Phobos, the inner satellite of Mars Prof George Darwin, in his well-known work on the tides, etc, suggested that Phobos was so near Roche's limit that future astronomers might witness its disintegration Dr E O. Fountain gives some useful calculations on the subject in the Journal of the British Astronomical Association for May He assumes as the tenacity of the material forming Phobos about 300 lbs per square inch, the figure for brick and cement. On this basis he finds that Phobos would still hold together even close to the surface of Mars, while in its present situation a satellite of 200 miles diameter could exist without destruction. He also finds that bodies some 200 miles in diameter could exist without destruction at the inner edge of Saturn's ring, so that the doctrine of Roche's limit can scarcely be invoked to explain the disintegration of the matter of the ring into such tiny fragments as those which appear to constitute the ring particles.

Research Items.

ENGLISH GYPSY CHRISTIAN NAMES.—In the second part of vol. i. of the *Journal of the Gypsy Lore Society*, which has been revived under promising auspices, is a contribution by Mr. E O Winstedt on English Gypsy Christian names. This question has hitherto been inadequately treated, and in this branch of Gypsy lore, as in others, there has been a tendency to confine attention too exclusively to Gypsies, and to regard them as more peculiar than they really are But recent research tends to show that many of their customs, superstitions, folk-tales, and peculiarities of dress are borrowed from the Gorgios among whom they have lived. It is only by foraging among parish registers and similar documents that the remarkable examples collected by Mr. Winstedt can be discovered Many are certainly of foreign origin, having been brought with them by gypsies as a relic of their travels, and the frequency of Greek names indicates a survival of their sojourn in Greek-speaking countries. Others, again, seem to be English names extensively modified by settlers in this country. These have been traced with much research and ingenuity, and the interest of Mr. Winstedt's paper to philologists and ethnologists is obvious.

SOCIAL ECONOMICS IN THE PHILIPPINE ISLANDS — The relation of religious beliefs and economics to the environment is well illustrated by an important memoir on the Ifugao, who inhabit one of the most isolated districts in the Philippines. They have practically no foreign market for their products, and for their imports they must pay middlemen's profits three or four times over as well as high transport charges. They live in a series of mountain valleys, and this isolation leads to hostility between the groups The country is fertile, but the climate most uncertain, the latter directly affecting crops and health, and indirectly, it has been a factor which the writer (Mr. R F Barton, University of California Publications on Archæology and Ethnology, vol xv. No 5) calls " one of the richest religions in the world," for in order to obtain the favour of good weather and consequent good crops, the Ifugao performs a round of religious feasts, the provision of animals for which is the principal economic motive in his life The uncertainty of the climate causes much disease, and expensive religious feasts must be given to relieve sickness " The wealth of the religion has arisen from the variation of climate and the rough and dangerous nature of the mountains, and the perils of the torrents and the landslides. Religion is a great factor, the greatest by far in the commercial activities of the tribe and in the economic activities of the male Ifugao " This survey of an isolated tribe living under special conditions which promote isolation and superstition, is most instructive

PARASITOLOGY IN S AFRICA.—In the *South African Journal of Science*, vol. xviii , 1921, among the reports of papers read at the South African Association for the Advancement of Science, we note Dr A. Porter's abstract on the life-histories of some trematodes, including the two African species of Bilharzia infecting man and the liver fluke of sheep, the intermediate hosts of which in S. Africa have been ascertained Prof H. B. Fantham records observations on parasitic protozoa in S. Africa, including an Entamœba—believed to be new—from the horse.

MYRIAPODA.—The attention of workers on this class may be directed to two recently published papers—one by Mr. H. W. Brolemann in Proc. R. Soc. Edinburgh, vol. 42, 1922, on material collected by Capt. W. E. Evans during the Mesopotamia campaign, comprising 17 species, and by Mr. R. V. Chamberlin, in Proc. U S Nat. Mus., vol. 60, art. 7, 1921, on the centipedes of Central America.

CRETACEOUS FOSSIL REPTILES IN INDIA.—Dr C. A. Matley, whose services were lent to the Military Accounts Department in India during the later stages of the war, took the opportunity of mapping in detail around the cantonment of Jubbulpore the cretaceous formations locally known as the Lameta beds, which are found underlying the great spread of trap-flows in the Central Provinces In a paper published in the Records of the Geological Survey of India (vol liii., Part 2), Dr. Matley shows that in this area the Lametas and trap-flows follow in conformable succession above the so-called Jubbulpore group of the Gondwana system of freshwater beds. Accepting for the Lametas an age of albian to cenomanian, based on correlation with the marine cretaceous beds of western India, the lowest trap-flows are probably not younger than middle cretaceous, while the Jubbulpore group, which was regarded by Feistmantel on palæo-botanical evidence as middle jurassic, should now be included in the cretaceous system. Dr Matley's work thus tends to restrict the stratigraphical range previously accepted for these associated formations, and his observations, which were necessarily hurried in places through official duties of an entirely different sort, indicate the desirability of making a detailed re-examination of the strata immediately below and intercalated with the Deccan trap-flows in the Central Provinces of India The Lameta beds are famous as having yielded the fossil bones on which Lydekker founded the dinosaurian genus Titanosaurus Dr. Matley, in the course of his work, collected further vertebrate remains from previously known localities and discovered some new occurrences The locality from which General Sleeman, the famous suppressor of " thuggy," first obtained fossil bones in 1828 has been explored systematically with the help of officers lent by the Geological Survey of India, and a large quantity of fresh material has now been obtained, including about 5000 scutes as well as some hundreds of bones, which will certainly yield results on critical examination of the greatest palæontological interest

THE STRUCTURE OF ROCKALL.—In June last year Dr. J. B Charcot, cruising in the *Pourquoi Pas?*, visited the little-known island of Rockall, which lies some 200 miles west of the Hebrides. One of his chief aims was to obtain rock samples in the hope of throwing further light on the origin of this curious rock In this Dr Charcot was successful, and to an account of his experiences in *La Geographie* for May 1922, is added M A Lacroix's report on the geological collections The prevailing rock of the island is a coarse-grained aegirine granite of a somewhat unusual but not unique type The so-called rockallite which was described by Prof. J. W Judd some twenty-five years ago, turns out to be relatively rare It is a fine grained rock with more aegirine than the normal granite, and it occurs only in patches. Previous to Dr. Charcot's visit the only rock specimens from the island were rockallite All the rocks contain elpidite, which is known also in certain beds in Greenland. Dredgings in the vicinity of Rockall brought to light basaltic rocks, probably the remains of a submerged plateau of basalt, as was suggested some

years ago by Prof. G. A. J. Cole. There can be little doubt that Rockall is the last remnant of a former extensive land surface.

THE GEOLOGICAL MAPPING OF THE GLOBE.—In these columns attention has been directed from time to time to the maps issued in connexion with regional memoirs, such as those on Australian states, Sinai, and Mesopotamia. We may now add Lange Koch's geological map of Palæozoic strata in north-west Greenland, 1 : 2,000,000, attached to his paper on "The Stratigraphy of North-west Greenland" (*Meddelelser fro Dansk. geol. Foren*, vol. v, No 17, 1920—foreword dated May 1921) In this memoir the earlier Palæozoic systems are shown to have been involved in the Caledonian folding, which is thus for the first time traced across the Atlantic interval. R C Wilson, in "The Geology of the Western Railway" (Geol. Surv. Nigeria, Bull. 2, 1922, price 17*s* 6*d*.), includes a coloured map of country north of Lagos, scale 1 : 250,000, and records Eocene beds near the coast, followed by areas in which composite gneiss is prominent. An immense amount of information as to geological knowledge of the countries bordering the Pacific has been brought together in the Proceedings of the First Pan-Pacific Conference, part 3, published at the office of the Honolulu Star Bulletin, 1921 M. Emm de Margerie (*Annales de Géographie*, vol xxxi., p. 109, 1922), in criticising, with a query, "Une nouvelle carte géologique du monde?" points out that the production of such a map is beyond the powers of any one geologist While indicating defects in a recent publication, he provides valuable notes on material not yet utilised. Hence his essay usefully records a number of publications on regions recently explored.

GLAZE STORM IN AMERICA.—The great glaze storm of February 21-23 in the Upper Lake region of the United States of America is discussed by Prof. A J Henry and Messrs J. E. Lockwood and D. A. Seeley of the U S Weather Bureau, and is published in the U S. *Monthly Weather Review* for February. A large amount of damage was done to overhead telegraph, telephone, and other transmission lines in the upper Mississippi Valley and in the States of Wisconsin and Michigan A serious loss was sustained by shade and ornamental trees and orchards, a loss which cannot be replaced within the lifetime of the present generation. The storm, in common with others of a similar nature, had a cold surface air current which was overrun by a warmer current, the rain which was condensed in the upper current falling upon objects having a temperature some degrees below 32° F. was frozen as it reached them. The diameter of the ice-covered wires varied from a few tenths of an inch to 2·5 in. or more, forming a rod of ice as thick as a man's wrist, and added to this was the weight of icicles which formed along the wires, often very close together, and varying in length from 3 to 12 inches Often 2 or 3 miles of telephone wires went down at one time At Oshkosh a small piece of ice-covered branch weighed 2 pounds, without the ice it weighed 2 ounces. In Michigan the ice, sleet, and snowstorm was one of the heaviest on record. Millions of dollars worth of property was destroyed. In many orchards, 25-75 per cent. of the older trees were broken off entirely. At Arcadia a short twig weighing 1 ounce had an ice coating of 2 pounds. Several observers reported the ice coating to weigh 20 to 40 times as much as the supporting branch or wire.

NEW THEORY OF CYCLONES.—During the last twenty years our knowledge of the actual movement of the air in a cyclone has increased materially, and it has become more and more difficult to reconcile it with the theory of cyclone formation advanced by Ferrel 60 years ago. It is only recently that the work of meteorologists in this country and abroad has led to a more satisfactory theory, which has been given a precise form by V. Bjerknes and his son J Bjerknes, in a series of papers dating from 1917 to 1921. A thoroughly readable account of the present state of the theory will be found in an article by Dr. E. Kuhlbrodt in the issue of *Die Wissenschaften* for May 26. According to Dr. Kuhlbrodt the north polar regions are covered by a cap of cold air which thins out as it extends downwards into temperate latitudes and ends in general about latitude 40°, but may disappear at latitude 50° over a few degrees of longitude. Above the cold cap is a considerable thickness of warm air derived from the south and having a motion to the east. Where the surface of separation of warm and cold air comes down to the earth's surface at an unusually high latitude a cyclone is produced, which is carried to the east by the movement of the warm air. The distribution of wind and weather to be expected in such a region is shown to be in agreement with observation.

WEATHER AT BLUE HILL, U S—Meteorological observations made at the Blue Hill Observatory, under the direction of Prof. Alexander McAdie, during 1921, are published in the Annals of the Astronomical Observatory of Harvard College. The observational data complete an unbroken period of thirty-six years, 1886–1921, and include pressure, temperature, wind direction and velocity, humidity, sunshine, cloudiness, and precipitation. It is estimated that the series should extend over at least fifty years for the establishment of proper normals. A table is given showing advance of the seasons for thirty-six years, 1886–1921. It is interesting to note that the earliest autumn frost for the whole period occurred on August 21 in 1908, and in this year the first snowfall in autumn occurred on December 7, which is the latest of the whole period, an anomaly which would scarcely be expected. The rainfall table giving the monthly amounts for the several years shows a large and varying range of measurement in all months. The average annual rainfall is 46·59 in., ranging from 4·7 in for March to 3·20 in for June

A DIFFERENTIAL REFRACTOMETER.—Messrs Bellingham and Stanley, Ltd, has constructed a differential refractometer for measuring very small differences between the refractive index of two liquids. The design of the instrument is based on the method described by Hallwachs The liquids are contained in a glass cell and are separated by a thin glass plate. Light from the source is admitted to the liquid of lower refractive index at grazing incidence on the separating glass plate, which it traverses and then passes through the second liquid at a small angle to the glass plate, the magnitude of this angle depending on the difference between the refractive indices of the two liquids By means of an observation telescope the axis of which is approximately in the plane of the separating glass plate, the limiting position of the emergent ray from the cell can be observed and the position measured by the screw motion which rotates the cell with its supporting table In the case of liquids having indices approximating to that of water a difference in index of 0·00001 corresponds to an angle of emergence of about ¼ of a degree. The instrument can thus be made extremely sensitive, and is particularly valuable for the detection of small quantities of impurities in liquids.

Annual Visitation of the National Physical Laboratory.

A LARGE number of visitors were present at the National Physical Laboratory on the occasion of the Annual Visitation on June 27. The guests were received by Sir Charles Sherrington, president of the Royal Society and chairman of the General Board; and Sir Joseph Petavel, Director of the Laboratory. As is usual on such occasions, the various departments were thrown open and an interesting series of exhibits was arranged, illustrative of the work carried on in the institution.

In the Department of Aerodynamics, exhibits were shown in most of the six wind tunnels. In the largest of these, which has a cross section of 14 ft. × 7 ft., an aerofoil model was set up showing the methods of measuring the lift and drag. The section of the aerofoil under test was on a scale approximately one-fifth of full size. In another channel were shown additions made to the standard type of balance, whereby for one setting of the model the component forces and moments in three directions can be determined. This represents a considerable saving of time in the process of testing. The discontinuous flow of air past a barrier was demonstrated in an effective manner by means of smoke released into the stream of air before it reached the obstacle. Other exhibits included an aeroplane model showing the method of obtaining the distribution of pressure over the wing, an apparatus used for determining the thrust and torque of model propellers, and an ingenious wind direction finder.

The additions to the Engineering Department, consisting of a large experimental shop and a set of offices, have been completed during the year and have much relieved the congestion. Among the exhibits were two machines for testing the efficiency of spur gears and chain drives. In both of these machines the regenerative principle is made use of, so that the power consumption is only that absorbed by the element under test. Thus, to determine the losses corresponding to an actual transmission of 100 h.p., a power of the order of 5 h.p. suffices. The efficiencies can be measured to an accuracy of 0·1 per cent. A new machine for testing reinforced concrete slabs and columns was also shown. The slab specimens can be tested in sizes up to 16 ft × 6 ft and 14 inches in thickness, and the columns from 8 to 20 feet in length; the maximum load is 60 tons. It was interesting to note that it was found possible to support the columns by means of knife-edge pivots. During the year, a plant has been completed for the production of asphalt road carpets. This enables the constituents to be mixed accurately in the proper proportions, prior to laying and testing in the standard road-testing machine. Other exhibits in this department included apparatus designed for the measurement of the temperature and pressure of the oil film in lubricated journals, the investigation of heat losses through pipe covers, the determination of the fatigue ranges of stress in materials by the strain method, and for the investigation of the detonation of a mixture of air and liquid fuels in closed vessels.

In the Metallurgical Department, a much-needed extension of space has been provided during the year by the addition of an extra floor on the Wernher building. Considerable attention has been devoted in this Department during recent years to the study of aluminium and its alloys, and examples were shown of an alloy developed at the Laboratory which is specially suitable for aeroplane engines. Pistons and piston rings of this material were on view. A specimen of aluminium was exhibited which had been submitted many times to an alternate treatment of rolling and melting without any effect on its tensile strength. A very effective experiment was shown on specimens of an aluminium-zinc alloy, which were heated in a furnace at a temperature of 370° C. and then quenched by immersion in water. Within a period of five minutes, a considerable generation of heat occurred—due to the breakdown of an unstable solid phase—which rendered the specimen almost too hot to be held in the hand. An interesting series of micro-photographs, taken during this period, showed the structural changes occurring, which are accompanied by great variation in hardness.

In the section of the department dealing with refractory materials, a new recuperative gas furnace, working under natural draught, and intended for glass melting, was running, while in the section of aeronautical chemistry the viscosity method for characterising deterioration of fabrics was demonstrated. Other exhibits in the Metallurgical Department were a high temperature thermostat arranged for obtaining very slow rates of cooling, and an ingenious relay for controlling furnace currents.

In the Heat Division of the Physics Department, various methods for the measurement of thermal conductivity were demonstrated. These included a new apparatus for dealing with thin sheets of material and for studying the effects of pressure on the thermal conductivity, a large scale apparatus for experiments on insulators for cold storage purposes, and a similar apparatus which has been used for measuring the conductivity of a series of building materials. A method for investigating the convection of heat in transformer oils was shown and also a device for the automatic operation of a ventilating valve with small changes of temperature of the air inside and outside a room. Various types of hygrometers were also exhibited.

In the Thermometry Division a new type of resistance bridge was shown with dials reading to 0·001° C., with a platinum thermometer of 10 ohms fundamental interval.

In the Radiology Division apparatus designed for the X-ray spectroscopic investigation of structure of materials, the measurement of radium salts, the standardising of barium platino-cyanide pastilles, the investigation of protective values of X-ray materials, and the X-ray examination of metals were exhibited.

In the Optics Division, various types of apparatus for measurement and specification of colour were shown. These included a Nutting monochromatic colorimeter, a Lovibond tintometer, a Bawtree colorimeter, and a trichromatic colorimeter for standardisation purposes designed and constructed at the Laboratory. In the latter instrument the mixing of the three primary colours is accomplished by rotating a periscopic prism which passes rapidly in front of three sectorial openings of variable angles in which the coloured filters are placed. Among the exhibits in this division was also a differential refractometer for liquids having nearly the same refractive index, while a new immersion method for measuring the internal bore of a glass tube was also demonstrated.

The Metrology Department (Glass Testing Section) showed a new equipment designed for the accurate calibration of hydrometers against a hydrostatic balance. The liquid in which the hydrometer is immersed is surrounded by a water bath controlled by a thermostat. The whole of this apparatus can be moved under a special balance from the scale pans of which are suspended two plummets of the same mass

but differing in volume by 100 c.c. The density of the liquid is thus obtained directly by weighing and is compared with the hydrometer under investigation. The balance is of special construction and is provided with inertia bobs at the ends of the arms to counteract the damping due to the movement of the plummets through the liquid. Other exhibits in the Metrology Department included a series of instruments for the precision measurement of engineers' gauges and a vertical interference apparatus for testing the flatness of surfaces, line standards and comparators.

In the Froude National Tank experiments to determine the resistance of a ship form in artificially created waves, and the method of taking continuous records of resistance, pitching angle and pitching period were demonstrated. The object of this work is to obtain data as to the loss of speed of different designs of ships under service conditions. It is interesting to note in this connexion that observations of full size ships have been taken by members of the staff in voyages across the Atlantic in three types of vessels, liners, cargo steamers, and oil tankers. Apparatus was also shown for determining forces on a ship's rudder, the manœuvring power of a ship's form, and the resistance of a seaplane model on the surface of the water.

Many interesting exhibits were on view in the various sections of the Electricity Department. The Photometry Division showed a method of determining the spectral distribution of energy in arcs having cores of different materials, and of measuring the transmission ratios of coloured glasses intended as standards for ships' navigation lights.

The Alternating Current Section demonstrated the speed regulation of a D.C. motor by means of a relatively small phonic motor directly coupled to it. The Direct Current Section showed apparatus for experiments on moulded insulators and other insulating materials, tests on buried cables and on energy losses in a 3-core cable with three-phase current.

In the Standards Section, an air gap for dielectric tests on mica and thin sheet materials was shown. This consists of very accurately flat steel plates 12 cms. in diameter, separated by distance pieces of quartz, so as to give an accurately parallel gap. The apparatus can be taken apart and the gap reproduced to within 0·0001 mm. In connexion with the above-mentioned apparatus, a machine of the optical lever type has been evolved for measuring the thickness from point to point of sheets of mica or other thin material.

A standard multivibrator apparatus for radio-frequencies was shown by the same section. In this apparatus a wave with a sharp peak is produced, having a frequency of 1000 per sec. From this, by the help of a highly resonant circuit, every harmonic up to the hundredth may be picked out, thus providing a series of accurately spaced radio-frequencies. The fundamental is kept constant to 1 part in 100,000 by a tuning-fork control. A second multivibrator, which can be controlled from the first one, has a fundamental of 30,000 per second and gives a further series up to 1,000,000 per second.

In the Wireless Section, directional measurements of spark and continuous wave stations were shown, the photographic reception of signals on a string galvanometer, and a new type of thermo-junction ammeter for high frequency.

Agricultural Research in Great Britain.

THE "assistant principal" at the Ministry of Agriculture, Mr. V. E. Wilkins, has prepared a valuable pamphlet,[1] which gives a useful account of the various forms of agricultural research that are being supported financially by the State. As is well known, the Ministry decided to concentrate research at definite institutions; Rothamsted is concerned with plant nutrition, soil problems, and plant pathology; Cambridge has entrusted to it plant and animal breeding, and animal nutrition; Long Ashton, a branch of the University of Bristol, deals with fruit growing and preserving; plant physiology is dealt with at the research institute attached to the Imperial College of Science; dairying at Reading; animal pathology at the Royal Veterinary College; agricultural zoology at Birmingham; helminthology at the London School of Tropical Medicine; agricultural economics in Oxford; plant breeding, with particular reference to Wales, at Aberystwyth; fruit growing and hops at East Malling; and nursery and market gardening at Cheshunt. Besides these research institutes and stations the Ministry has set up a system of advisory centres from which information in respect of specific subjects is disseminated by advisory officers who also, in many cases, undertake a certain amount of research.

(a) *The Soil and its Effect on Plant Growth.*—This fundamental subject has been entrusted to the Rothamsted Experimental Station, which is concerned, among other things, with the examination of the soil in its relation to bacteria and protozoa, and an account is given of the arduous nature of the research along these lines. The nitrification of organic nitrogen alone has demanded the services of eight research workers, who in many cases have worked night- and day-shifts. An interesting form of investigation undertaken at this station is concerned with the production of artificial farmyard manure. During the later stages of the war, and subsequently, until the agricultural policy of the Government was altered, there was a prospect of a superabundance of straw, more, in fact, than could be dealt with as food and litter by farm animals. The Rothamsted investigators set about devising a means of converting this straw directly into farmyard manure, and the results are most encouraging, although now, with the reduced area of tillage land, the necessity for such conversion is no longer pressing.

At the same station much work has been done on the influence of colloids on the water-content of soil, and on the mechanical operations concerned with tillage. Most ingenious electrical methods are also being exploited to determine the relation between soil acidity and crop production, and the list of publications that have been issued from Rothamsted during 1920 and 1921 shows the extraordinarily varied character of the work being conducted at this famous station.

(b) *Plant Breeding.*—The problems that are being investigated along this line are concerned with the baking qualities or strength of English wheat, with the production of cereals possessed of a straw stiff enough to stand up under adverse circumstances, with immunity to disease, with the increase of the number of grains in the ear, with the production of hardier varieties of winter oats, with the relationship of nitrogen in barley grain to the quality of the produce, and with the production of potatoes immune to wart disease. These problems are being dealt

[1] "Ministry of Agriculture and Fisheries. Agricultural Research and the Farmer: A Record of Recent Achievement." By V. E. Wilkins. Pp. 168. (London: H.M. Stationery Office, 1922.) 2s. 6d. net.

with chiefly at Cambridge; while Aberystwyth, the Welsh plant-breeding station, is concerned principally with the discovery of the production of new and improved herbage plants which must be so important in the West of England from the point of view of pasture and meadows.

(c) *Plant Physiology*.—The chapter on this subject opens with a suggestive discussion on the fundamental principles involved in crop production. These principles are concerned with the causes that determine heavy cropping and light cropping, resistance to disease, and the formation of flower-buds on fruit-trees. The electrical treatment of crops is also receiving attention at Rothamsted, the Harper Adams Agricultural College, and on a station near Dumfries. To quote from the report, "There is no doubt that electrical discharge will increase plant growth, and it is hoped that it will be found possible to continue the patient experimental work that has been going on for some years, for it seems certain sooner or later that electricity must play an important part on the farm in increasing crop production."

(d) *Fruit-growing and Preserving*.—Fruit problems are being dealt with mainly at the horticultural station at Long Ashton and at East Malling in Kent. Much suggestive work has been done on the problem of fruit stocks, a subject that has hitherto been very confused and unsatisfactory. The Paradise stock, for instance, has been proved to be a mixture of several varieties, and it would appear that even the crab stock may be graded into several classes, each of which has a distinct influence on the scion that is grafted or budded on to it. This subject is inseparably connected with the development of the root system, a line of research to which the late Mr. Pickering gave much attention, showing that it was quite unnecessary to give the amount of attention that is usually bestowed upon planting. This unexpected result appears to have been confirmed at Long Ashton, the original root system playing practically no further part in the growth of the transplanted tree, which seems to develop a new root system independent of the old. Work on ringing, pruning, disbudding, etc., also promises to have an influence on commercial production, while much light is being thrown upon the problem of manuring of fruit. This station has also contributed largely to our knowledge of the factors that determine the production of high-grade cider and perry.

(e) *Plant Diseases*.—In no department of the Ministry's scheme has more activity been shown than in the direction of plant diseases. At the School of Botany in Cambridge special attention has been given to the silver leaf disease, a trouble that is increasing markedly in this country, and is now no longer confined to plums, but has spread to apples and other fruit-trees. How destructive the disease may be is proved by the fact that an apple-orchard of about 6 acres, near Wisbech, showed more than 1000 trees attacked by this disease, the cause being attributed to carelessness in pruning and the neglect to protect the wounds thus caused.

Space does not permit of the publication of details in the departments of animal husbandry, animal breeding, dairying, animal diseases, and agricultural economics, but enough has probably been said to show what an enormous change has come over the country in respect of the provision for agricultural research under the enlightened policy pursued by the Ministry of Agriculture.

The Magnetic Work of the Carnegie Institution.[1]

By Dr. C. Chree, F.R.S.

THE primary object of the volume referred to below is to chronicle the results of observations made on land by members of the Department of Terrestrial Magnetism of the Carnegie Institution, Washington, from 1914 to 1920. During that period 1747 stations were occupied, bringing up to 4028 the number of land stations occupied since the world survey began in 1905. Even the general reader will find much to interest him in the field observers' reports on pp. 98-222. Mr. F. Brown, for instance, who travelled over large areas in China, Mongolia, Manchuria, Upper Burma, the Cameroons, and French Equatorial Africa, and who crossed Central Africa from Angola to Mozambique, relates adventures with brigands, lions, witch doctors, and native kings.

There is also a general account of the land instruments employed, references being made to earlier volumes for constructional details. Plate 2 gives illustrations of the instruments supplied by the Department to Captain Roald Amundsen's *Maud* expedition. On p. 9 there is an explanation of the two standards which have been used, the earlier denoted by C.I.W. (Carnegie Institution, Washington), the later by I.M.S. (International magnetic standards). The use of the latter term for standards which have not received international sanction is somewhat open to criticism.

The observational results occupy some 67 pages, and later in the volume there is a detailed description of the stations. Some of the more picturesque places visited are illustrated in seven plates.

Mr. J. A. Fleming describes the construction at the headquarters of the department, at Washington, of a new non-magnetic building for experimental work. It is of considerable size, 28 ft. × 53 ft. ground area, of double-walled concrete. Provision is made for the supply of water, gas, compressed air, and electric circuits for direct and alternating current. The cost, exclusive of the internal equipment, was 8500 dollars. A magnetic survey made after the completion of the building showed differences of 2′ in dip and 25γ in horizontal force between the north and south ends.

Mr. H. W. Fisk discusses errors arising from minute pivot defects in dip needles. He advocates the use of at least four needles at each station, so as to recognise with certainty when an individual needle becomes faulty.

A description by Mr. S. J. Barnett of a new sine galvanometer for determining H (horizontal force) is of special interest at the present moment. The construction of similar instruments has been simultaneously in progress in America, Japan, and England. The instrument described by Mr. Barnett is much smaller than that recently described to the Royal Society by Mr. F. E. Smith. Its coils, of approximately 30 cms. diameter, are wound on Carrara marble. An approximation is made to the Helmholtz arrangement, but the coils are really spirals. It is hoped to measure H with an error less than 1 in 10,000. A preliminary comparison with the I.M.S. standard mentioned above gave a discrepancy of only 0·7γ, or 1 part in 25,000, but the constants of the instrument are as yet to some extent provisional.

Mr. J. A. Fleming also deals with the results of comparisons, direct and indirect, between Carnegie Institution instruments and the standard instruments

[1] Researches of the Department of Terrestrial Magnetism, vol. iv. Land Magnetic Observations 1914-1920. By Dr. L. A. Bauer and others, and Special Reports. (Publication 175). Pp. vi+475+9 plates. (Washington: Carnegie Institution, 1921.)

in use at a number of observatories. He claims that the results show, first, that the Carnegie Institution standards are in every way satisfactory, and second, that "the absolute precision obtainable with carefully designed magnetometers and (dip) inductors, provided instruments are carefully used and comparisons are made with reliable standards at least every two or three years, is of the order 0'·2 in declination and inclination and of the order 0·00015H (*i.e.* 3γ in England) in horizontal intensity." If this be true, the gain in accuracy to be hoped for from coil instruments is not great. If, however, as stated on p. 468, a complete observation of H with the coil instrument occupies only 2 minutes, its use at an observatory would represent a great economy of time, always provided little time is spent on keeping the apparatus up to the mark.

However this may be, what is really more wanted is a coil instrument for measuring V (vertical force). Base line values of V curves are at present dependent on dip circles or inductors. Even if the accuracy claimed by Mr. Fleming for dip inductors be conceded, it must be remembered that an error of 0'·2 in the dip at a place where the value of H is only 0·03 (the approximate value at the base station of the Australasian Antarctic Expedition 1912-13) leads to an error of about 90γ in V. Thus a coil instrument which could give V directly, to within ±5γ even, would be an immense improvement on a dip inductor for use in high latitudes.

New Social Coleoptera.[1]

By Dr A. D. IMMS.

IF we regard as truly social only those insects in which the parent, or parents, live with their offspring, protecting and feeding them, there have been known hitherto but three groups of beetles which come into this category, namely, the Platypodidæ, Scolytidæ, and Passalidæ Prof. W. M Wheeler has recently added to the list two genera of Silvanid beetles belonging to the family Cucujidæ, discovered by him in British Guiana The beetles in question are *Coccidotrophus socialis* and *Eunausibius wheeleri* both of Schwartz and Barber The bulk of his observations concern the first-mentioned insect, the other species being apparently rare. The beetles enter the hollow petioles of a Leguminous tree Tachigalia and either bore their way in, or gain admittance through perforations previously made by other insects They enter either as a single pair, or one beetle enters and is very soon joined by an individual of the opposite sex. Upon taking possession of their future habitation the beetles remove any loose pith, or the remains of previous tenants, by pushing this debris into the pointed ends of the cavity by means of their flattened heads This behaviour brings the insects into contact with the outermost layer of pith adhering to the walls of the cavity, and certain strips of nutritive parenchyma The latter tissue forms the food of the beetles, and is also shared by young Coccidæ of the species *Pseudococcus bromeliæ*, which soon begin to enter the petiole-cavity By means of the feeding action of the beetles, the strips become converted into grooves, the coccids stationing themselves in a row in each groove The beetles carefully avoid soiling their food material and store their frass in the areas between the grooves They lay their eggs along the frass ridges, and the larvæ which hatch out feed upon the same nutritive parenchyma as their parents When mature, they construct brown cocoons within which pupation occurs The beetles emerging from the latter remain in the petiole with the original pair, they mate and produce eggs and larvæ in turn, thus leading to the climax stage of the colony, which may eventually consist of several dozens of beetles of both sexes, and many larvæ and pupæ in all stages of development The Coccidæ also increase in number, so that the cavity of the petiole sometimes becomes crowded with inmates In the meantime, the old and exhausted beetles die off, and their bodies are consigned to the refuse accumulations already mentioned When this crowded condition is reached, beetles begin to leave the colony either singly or in pairs and, seeking other petioles, thus found new colonies

Both the larvæ and imagines of the *Coccidotrophus* solicit honey dew from the coccids by "stroking" the latter by means of the antennæ The relations of the beetle to the coccids, moreover, are physiologically similar to those of symphile beetles to host ants that supply them with regurgitated liquids *Coccidotrophus*, like the symphiles, has specially modified antennæ and labium, such modifications occurring in both the larvæ and adults This type of relationship with Coccidæ has not been noted hitherto in any Coleoptera and, apart from ants, very few insects are known to have developed the ability to solicit honey dew from among the Homoptera.

It appears that the Sylvanids have a more primitive social life than any of the three families of beetles previously alluded to, but there is no definite preparation of larval food by the parents. Their colonies represent a stage in social development intermediate between the families mentioned and the merely gregarious species of Cucujidæ. For further details, and many interesting observations on the numerous and heterogeneous "biocœnose" of other insects associated with the plant Tachigalia, the reader is referred to Prof Wheeler's original paper

Spectroscopic Studies of Stellar Velocities.[1]

By Dr WILLIAM J. S LOCKYER.

IN order to determine the distribution and motion of stars in space it is necessary to know four important facts about each star The first is its position, known as its Right Ascension and Declination; the second is its proper motion, *i e* the movement at right angles to the line of sight, the third is the radial velocity or movement towards or away from the earth; and lastly, the parallax or distance of the star from the earth

During the last few years the accumulation of a large amount of such data, extending over many years, has led astronomers to the important problem of investigating the systematic motions of the stars

[1] "The Radial Velocities of 594 Stars," Publications of the Dominion Astrophysical Observatory, Victoria, B C. (vol 2, No. 1), by J S Plaskett, W E Harper, R K. Young, H. H Plaskett (Ottawa, 1921)

and their distances, thus leading to our knowledge of the distribution of stars in space, and finally to the structure of the universe.

At the present time, however, data are most lacking regarding stellar radial velocities, and any attempt to increase our knowledge in this respect deserves particular attention. It is, therefore, very satisfactory to know that, when planning the equipment of the Dominion Astrophysical Observatory of Victoria, B.C., the first consideration was given to its suitability for this class of work, which it is proposed to make the great feature of the new institution. Quite recently the first volume of measures has been published, and this comprises the determination of the radial velocities of 594 stars between the fifth and eighth magnitudes, the velocities of which have not been measured before.

The work was commenced in May 1918 by the Director of the Observatory, Dr. J. S. Plaskett, and Dr. R. K. Young. In the following year Mr. W. E. Harper and Mr. H. H Plaskett joined the staff, so that this volume is the outcome of the endeavours of these four observers, who together made the observations, the measurements and the reductions of the spectrograms, as no computing assistance was available.

The introduction to the volume describes briefly the telescope, the spectrograph, the observing arrangements, measuring machines, wave-lengths of spectral lines employed, etc. The telescope was the large 72-inch reflector, and the spectroscope was used with the Cassegrain combination of the telescope The regulation and control of the temperature in the spectrograph was at first attained by the use of a mercury contact thermometer actuating a special relay, but this was replaced later by the installation of a Callendar recorder Considerable attention was devoted to the wave-lengths of the lines employed in the reduction of the spectrograms, and the system eventually adopted was one developed by Dr. Young, which is to some extent a compromise of different methods and systems used by various observers. Tables showing the standard wave-lengths employed are given, and they indicate the wave-lengths used for B-type stars and for A- to F-type stars, together with a list of iron comparison lines.

The work accomplished may be briefly summarised by referring to the results of the measures which are brought together in various tables The first contains the mean velocities, with their probable errors, of all stars, 537 in number, assigned to be of constant velocity, including their positions, magnitudes, spectral types, etc. Next follows a summary table of the velocities of the systems of all spectroscopic binaries, the orbits of which have been determined at the Victoria Observatory. Table IV. gives complete information as regards the details of all the 3287 radial velocity plates of the 537 constant velocity stars, an average of 6·1 plates per star. This information is concise, compact, and in a convenient form, and will be valuable for detail reference when required. Similar detailed information is given in Table V. with respect to 206 plates of 35 probably binary stars.

It is interesting to make a short reference to the accuracy of the determinations of the radial velocities, because this accuracy depends to a very great extent on the definition of the lines in the star's spectrum under examination. Thus, some spectra have clean-cut lines which render their measurement easy, while others exhibit fuzzy lines, making measurements difficult. The authors have, therefore, divided the probable errors into three classes. The first includes stars of spectral types between F0 and M (excluding some early F stars) which give the most trustworthy values; the probable errors for these range between $\pm 0{\cdot}1$ and $\pm 1{\cdot}0$ kms. for the mean velocity obtained from all plates, and between $\pm 0{\cdot}2$ and $\pm 2{\cdot}5$ kms. for a single plate. The second main class includes about one-fourth of the A-type, about two-thirds of the B-type, and the early F-type mentioned above. The probable errors for this group are given as ranging from $\pm 0{\cdot}5$ to $\pm 1{\cdot}5$ kms. for the mean velocity, and from $\pm 1{\cdot}2$ to $\pm 3{\cdot}5$ kms. for a single plate.

The last group embraces mostly A-type stars with the addition of a few B- and O-type, the lines of which are diffuse, broad, and frequently weak. For these the probable errors range from $\pm 1{\cdot}0$ to $\pm 3{\cdot}8$ kms. for the mean and from $\pm 2{\cdot}5$ to $\pm 10{\cdot}0$ kms. for a single plate.

The original programme as to the number of photographs of the spectrum of each star to be secured, namely, six plates for each star with well-defined lines and eight or ten plates with poor lines, was almost carried out; the whole system of velocities here deduced is therefore homogeneous and a high grade of accuracy has been maintained. The radial velocity values are the result of a great amount of painstaking care, and their early publication is evidence of the industry that has been displayed in all stages of the research.

Geology of Antarctic Lands.

A USEFUL reference to recent summaries of the geological features of Antarctica occurs in the Proceedings of the first Pacific Conference, part iii. p. 644 (1921). It is unfortunate that the various researches based on the results of different British expeditions have not been carried out in a common clearing-house and published as an interlocking series. At present three sets of quarto publications are appearing in our libraries, two of them under the auspices of the Royal Society of Edinburgh, and one under those of the Trustees of the British Museum. Mr. J. M. Wordie's observations on the Weddell Sea area (Shackleton expedition, 1914–17) have been already noticed (NATURE, vol. 109, p. 218). The geological results of the expedition from the Falkland Islands in 1913, financed by Messrs. Salvesen of Leith, are now described by the leader, Mr. D. Ferguson ("Geological Observations in the South Shetlands, the Palmer Archipelago, and Graham Land," Trans. Roy. Soc. Edin., vol. liii. p. 29, 1921). The unrest in the earth's crust in Oligocene and Miocene times is illustrated by great outpourings of basalt in the South Shetland Islands. The later lavas of the series are notably columnar, and are correlated with similar rocks in Patagonia. Volcanic activity continued almost down to recent times, and there is a series of andesitic tuffs and lavas that go back to Jurassic or early Cretaceous age. The photographic landscapes in this memoir are of unusual excellence. The rocks collected abundantly by its author, are described by G. W. Tyrrell in a separate memoir (*ibid* p. 57). They include the varied intrusive masses of Graham Land and its group of islands, and the red adamellite of Mount Theodore, "the most imposing natural feature" of the district. Mr. Tyrrell regards these older igneous rocks as distinctly Andean in type.

Dr. H. H. Thomas (*ibid.* p. 81) deals with the rocks and minerals collected from islands of the same region by Mr. Innes Wilson, of the Falkland Islands, in

1916–17, [illegible] boulder near Port Lockroy in the [illegible] Channel. The description of the varied lavas of Deception Island in both this and Mr. Tyrrell's paper is surely an argument in favour of collation and co-operation.

The reports of the British Antarctic ("Terra Nova") Expedition of 1910, published by the British Museum, are concerned, however, with another quadrant of the antarctic region. In the geological series, Nos. 3 and 4, recent and older sedimentary deposits are described by Mr. F. Debenham, from his personal observations as geologist to the expedition. Metamorphic rocks are dealt with in No. 5; but their relationships in the field are as yet but little known. Dr. A. Smith Woodward's account (No. 2) of "Fish remains from the Upper Old Red Sandstone of Granite Harbour," including Bothriolepis, provides more definite information. The remoteness and perils of the district excuse the uncorrelated nature of the results, and no doubt also explain the handsome method of their presentation in the year 1921–22.

G. A. J. C.

Durability of Optical Glass.

By Dr. JAMES WEIR FRENCH.

IT is the custom of optical glass manufacturers to issue long lists of types characterised by their optical constants, without much regard to their qualities of durability, which are only occasionally indicated. To the practical computer these lengthy lists are not imposing. Experience has taught him that the number of sufficiently trustworthy types is really very limited, and that only in exceptional circumstances, that fortunately do not frequently arise, may an extension of his list be justified. But while the possibility remains that glass of an unstable kind may be used in the construction of his instruments, the optician has cause for anxiety in the knowledge that his reputation as well as the glass may become tarnished.

The British Scientific Instrument Research Association, the function of which is to provide for the industry the leaven of science, has been charged with the investigation of the durability of glass. According to the admirable report[1] that has recently been issued, "the object of the Research was to determine how far it was possible to establish simple tests by which the durability of different types and varieties of optical glass could be quickly ascertained without awaiting the results of experience by actual use over an extended period." To what extent this object has been attained may be realised from the frank confession at the conclusion of the report, that "it is not possible to recommend any simple test by which the durability of an optical glass can be determined, with such reliability as to avoid the chance of misleading users of the glass in some one or other application of it." With this pessimistic conclusion it is difficult to agree, as the object has already been attained in the workshop, if it is agreed that it is the reflecting or transmitting qualities of the surface with which the optician is concerned.

From the report it appears that numerous tests of Continental and British types of optical glass have been examined by the iodoeosin test of Mylius, the autoclave water and steam tests at four and two atmospheres of pressure, and the "dimming" test evolved by the Royal Arsenal Directorate of Chemical Inspection, which co-operated in the research. This dimming test is really an elaboration of the Zschimmer test. The three tests as applied indicate merely to what extent alkali can be dissolved from the surface, and, as is to be expected, the flint glass types appear more durable than the crown types—a conclusion that is misleading, as the report rightly indicates. Our industrial atmosphere unfortunately contains sulphuretted hydrogen, and if in the dimming test an atmosphere more representative of reality had been employed, the flint types would have been placed more nearly in the order accorded to them by Faraday.

The report confirms the interesting fact, already known in the workshop, that in the glass-polishing process alkali is dissolved from the surface layer, which, with a few exceptions, becomes more durable. Workshop experience shows that a new cloth polisher tested with litmus will usually be found to be slightly acid; after a few hours of working it will be neutral; and thereafter it becomes strongly alkaline. A pitch polisher reacts similarly, but it does not retain the dissolved alkali to the same extent.

The optician is concerned in practice not so much with those so-called optical glasses that are visually affected by the tests referred to, as with those that are labelled as being durable and unaffected. If a well-polished specimen of the most durable crown glass be boiled in water at atmospheric pressure for two hours and its reflecting power be then tested by means of a multi-reflection photometer, a loss of ½ per cent. per reflection may be detected. After boiling for eight hours, the loss will be about 2 per cent., but thereafter the rate diminishes.

The drastic autoclave tests adopted in the research are not necessary to demonstrate how many of the types included in the optical glass-makers' lists are vitreous substances of but little value and a source of danger to the unwary.

[1] Report of an Investigation on the Determination of the Durability of Optical Glass carried out by F. Haigh. Pp. 51 + 10 plates. (British Scientific Instrument Research Association, 26 Russell Square, W.C. 1.) 7s. 6d.

Volcanic Activity in Nigeria.

REPORTS have been received by the Governor from Mr. A. A. Reading, of the Bibundi Estate, of a recent volcanic eruption in the Cameroons Mountain, near the coast of Nigeria. Repeated earthquake shocks commencing on February 3 last were followed by an eruption at an altitude of about 4000 feet on the north-west side of the mountain, giving rise to a lava-stream which flowed down in the direction of the Bibundi Estate, and entered the plantation area on March 3. The lava extended, roughly, one-third of a mile out to sea, and huge columns of steam were continually ascending. Attempts to photograph the scene failed on account of the dense smoke and ashes. The centre of the group of craters was estimated to be distant 9900 yards from the house at Bibundi Beach on a magnetic bearing of 128°, and the height above sea-level was believed to be about 4150 feet.

In May the northern stream was still advancing, and threatened to reach the sea along the water-courses on each side of Dollmanshohe. Sometimes there was a loud noise resembling that of a blast

furnace; at other [illegible] that sounded [illegible] there were showers of ashes, which [illegible] that they broke the leaves of the palm trees.

When on open ground the lava stream came along like a wall of red-hot rock 30 or 40 feet high, which kept falling away in front as it advanced, but when it came down the deep ravine between Wernerfelde and Retzlaffelde, it flowed like a red-hot river moving at the rate of about 2 feet a minute. Mr. Reading threw a big stone on it to see if it would make a splash, but although it was moving and looked liquid, the stone bounded off just as if the lava were solid rock.

Since the outbreak of the volcano no severe earthquake shocks have been experienced, though the house was frequently felt to be shaking and two or three slight shocks were noticed.

Mr. Reading went round the edge of the lava in a canoe where it projected into the sea. He could not approach nearer than about 300 yards on account of the heat. At that distance the sea was so hot that he could not put his hand into it, and dead fish abound.

University and Educational Intelligence.

BIRMINGHAM.—Applications are invited from graduates in medicine of the University, of not more than five years' standing, for the Walter Myers travelling studentship (value 300*l*. for one year) for research in any branch of medicine or pathology approved by the selection committee. The studentship is tenable at any university, laboratory, or other approved institution, and the holder must devote his whole time to research Full information is obtainable from the Registrar of the University.

LEEDS.—A Gas Research Fellowship, value 200*l*. per annum, established by the Institution of Gas Engineers at the University of Leeds for the prosecution of post-graduate research in gas chemistry, has been awarded to Mr. S. Pexton. For the last two years Mr. Pexton has worked in the department of coal gas and fuel industries of the University.

LONDON.—Applications are invited for the William Julius Mickle fellowship, which is of the value of at least 200*l*., and awarded annually to the man or woman resident in London and a graduate of the University, who, in the opinion of the Senate, has done most to advance medical art or science during the preceding five years Particulars respecting the appointment may be obtained from the principal officer of the University. All applications for the fellowship must reach him by, at latest, October 2.

ST. ANDREWS.—The honorary degree of LL.D. will be conferred on the Prince of Wales on the occasion of his contemplated visit at the end of September. There will be no public graduation ceremony.

THE Commissioners of the Exhibition of 1851 announce that Senior Studentships for 1922 have been awarded to the following: Mr. J S Buck (Liverpool), research student in chemistry, of the University of Liverpool; Mr. G. T R. Hill (London), research student in aeronautics, of the University of London, University College, late experimental engineer and pilot to Handley Page, Ltd.; Mr. A. E. Ingham (Cambridge), research student in mathematics, of the University of Cambridge; Mr. J. E Jones (Victoria), lecturer in mathematics, of the University of Manchester; and Mr. C. E. Tilley (Adelaide and Sydney), research student in geology, of the University of Cambridge. Science Research Scholarships (Overseas) have been [illegible] Toronto [illegible] University [illegible] sity of British Columbia), for physical chemistry; [illegible] Marie Bentivoglio (University of Sydney), for crystallography; Mr. J. S. Rogers (University of Melbourne), for physics; Mr. J. C. Smith (University of New Zealand), for chemistry; and Mr. I. Low (University of Stellenbosch), for meteorology.

DR. W. D. HENDERSON, professor of zoology in the University of Bristol, has been appointed Ray Lankester Investigator at the Marine Biological Laboratory, Plymouth.

THE *Chemiker Zeitung* announces that the Society of Friends of the University of Jena has at its first annual meeting granted a sum of 700,000 marks for scientific purposes and 200,000 marks for the assistance of students. Of the first sum, 200,000 marks is for the Chemical Institute.

AN appointment is to be made by a committee of the Royal College of Physicians of London and of the Royal College of Surgeons of England of a Streatfeild research scholar. The scholarship was founded for the promotion of research in medicine and surgery and is of the annual value of about 250*l*, tenable at the discretion of the committee for three years. Applications, marked "Streatfeild Scholarship," and stating the nature of the proposed research and where it will be carried out, should reach the Registrar of the Royal College of Physicians of London, Pall Mall East, S.W.1, on or before October 2.

STATISTICS for 1920–21 of 93 State Universities and State Colleges have been published by the United States Bureau of Education (Bulletin, 1921, No. 53), under the heads—teaching force, student enrolment, and property and income. Most of these institutions were originally "Colleges for Agriculture and Mechanic Arts," and their agricultural and engineering schools are still far larger than all their other professional departments put together; but nearly all of them have departments of arts and sciences, and seventeen have graduate departments with not less than 50 students each. The largest teaching staffs are maintained in the following universities: California (1016), Cornell (905), Minnesota (837), Illinois (780), Wisconsin (731), Ohio (569), and Michigan (543). Thirty-four other institutions have more than 100 teachers. Of the total number of teachers (about 15,000) one-sixth are women. Salaries of presidents (most of whom are provided with free quarters in addition) range in general between 5000 and 12,000 dollars; those of professors between 2000 and 6000. The student (regular term) enrolments in the seven large universities named above were: 14,145, 5771, 11,282, 8739, 7573, 7584, and 9611. Forty-two other institutions have enrolments exceeding 1000. Women students constitute nearly a third of the total. Besides the regular term students there are some 60,000 summer school students, of whom nearly two-thirds are women. Almost every one of the State universities and State colleges holds a summer school. Endowments exceeding, in each case, five million dollars, are possessed by the Massachusetts Institute of Technology, Cornell University, and the universities of Texas, California, and Washington. It is remarkable that in no less than five States the private benefactions received by the State universities and State colleges during the year amounted to one-[illegible] or more of their total income.

[illegible]—An Italian engineer and mathematician, Stratico held professorships at Padua and Pavia, where he assisted Volta in his physical work, while under the rule of Napoleon he became an inspector of roads and bridges. He was also the author of works on hydraulics.

July 17, 1794. **John Roebuck died.**—The friend of Joseph Black and Watt, Roebuck was trained as a doctor and practised for a time at Birmingham. Turning his attention to chemical manufacture, he was successful in introducing leaden chambers in place of glass ones in the manufacture of sulphuric acid. In 1760 he founded the famous Carron Iron Works on the river Carron in Stirlingshire, but though a sound metallurgist, his business operations failed financially.

July 17, 1857. **Pierre Louis Frederic Sauvage died.**—Remembered as one of the independent inventors of the screw propeller, Sauvage was well known as an ingenious mechanician, and had works in the neighbourhood of Boulogne. He patented the propeller in 1832, but reaped no benefit from it; and though granted a pension by Louis Philippe, the failure of his scheme affected his mind and he died in an asylum. A statue of him was erected at Boulogne in 1881.

July 17, 1886. **David Stevenson died.**—A member of the well-known Scottish family of lighthouse engineers, Stevenson was trained as a mechanic, made surveys, wrote scientific papers, and with his brother Thomas (1818–1887) designed and built 28 beacons and 30 lighthouses in various parts of the world. He also took a leading part in the introduction of paraffin in place of colza oil.

July 17, 1891. **Willoughby Smith died.**—Entering the service of the Gutta-Percha Company in 1848, Smith superintended the making and assisted in the laying of the first submarine cables, and became chief electrician and manager of the Telegraph Construction and Maintenance Company. He made experiments on coating wire with gutta-percha, introduced improvements in cable manufacture, and was connected with the various Atlantic cable enterprises. In 1882 he served as president of the Society of Telegraph Engineers, now the Institution of Electrical Engineers.

July 19, 1879. **Louis Favre died.**—The son of a Swiss carpenter, Favre learned his father's trade and afterwards became noted as a builder of railways in the south of France and in Switzerland. In 1872 he became the engineer of the St. Gothard's tunnel, in the construction of which he made use of compressed air as suggested by Colladon. This tunnel is 14,900 metres in length. Favre's death occurred suddenly in the tunnel a short time before its completion.

July 22, 1869. **John Augustus Roebling died.**—One of the greatest bridge builders of last century, Roebling was a native of Germany, being born on June 12, 1806, at Mulhausen, Thuringia. He graduated from the Polytechnic School at Berlin, and in 1831 emigrated to the United States, where, after experience in canal and railway engineering, he founded a wire-rope manufactory. He constructed a wire-rope suspension aqueduct and a bridge over the Monongahela River, and suspension bridges over the Niagara Falls and the Ohio River, the latter having a span of 1057 feet. The success of his work led to the acceptance of his design for a great bridge over the East River to connect New York and Brooklyn, and it was while superintending the laying out of [illegible]

[illegible]

Royal Microscopical Society, June [illegible]—[illegible] Cheshire, president, in the chair.—**A. Chaston Chapman**: The use of the microscope in the brewing industry. The use of the microscope for research and control purposes has been directly responsible for greater technical advances and, indirectly, for more far-reaching discoveries in brewing than in any other industry. The larger breweries have laboratories in which both chemical and biological tests are carried out and much time is devoted to the examination of yeast, to the forcing of beers as a test of stability, to the testing of the efficiency of the air-filters, etc. The successful conduct of brewing operations depends almost entirely on such control work. The introduction of the microscope into the brewery as the result, chiefly, of Pasteur's investigations, has been responsible for the replacement of empirical methods by processes based on scientific knowledge.—**J. Strachan**: The microscope in paper-making. The microscope was introduced into the industry by amateur microscopists more than a century ago, and during the past twenty-five years, which have witnessed the application of exact scientific methods to paper-making, the technologist found the microscope already in common use. The microscope is used in the paper-mill chiefly for the analysis of paper and of its raw materials and in controlling the blending and preparation of these substances. It has also been applied to the beating process, which is largely a matter of colloid physics, and to sizing, dyeing, impurities in air and water, the valuation of new raw materials, etc. In spite of recent research work, which indicates that the cellulose basis of plants is of a uniform chemical composition, and that X-ray spectrographic methods have proved this substance to be of definite crystalline character, the constitution of cellulose remains unsettled. No important work had been done on its refractive index (about 1·555). Microscopic work on this matter and the application of the polariscope and ultra-microscope would probably yield important evidence.

Mineralogical Society, June 27.—Dr. A. Hutchinson, president, in the chair.—**A. Brammall** and **H. F. Harwood**: The Dartmoor granite; its accessory minerals and petrology. Minerals of general occurrence: tourmaline, ilmenite, magnetite, apatite, monazite, garnet, zircon [(1) in water-clear, small crystals, (2) in tawny, zoned, larger, and more abundant crystals], pyrites and pyrrhotine. More restricted: fluor (colourless, blue, and purple), topaz, cassiterite, andalusite, sphene, anatase, barytes. Biotite is abundant, muscovite is scanty. Streams have yielded, in addition, rutile, brookite, and blue-green anatase. Analyses are given of granite-types (bulk), biotite, porphyritic felspars (baryta-bearing) and some accessory minerals. In the tor area (Haytor-Widecombe), the granite occurs as successive sheets or flows, differing appreciably in chemical composition. The texture becomes coarser, porphyritic felspars become more abundant and richer in plagioclase content, and the percentage of biotite and accessories increases with vertical descent in a flow. The relationship of topography to pseudo-bedding, jointing, veining, and probable faulting is discussed.—**W. F. P. McLintock** and **F. R. Ennos**: On the structure and composition of the Strathmore meteorite. From microscopical examination of thin sections of this meteorite, stones of which fell in Perthshire and Forfarshire on December [illegible] 1917, the structure is that of the intermediate chondrites [illegible]. An apatite-like mineral is present [illegible] analyses of the magnetic and non-

magnetic portions agree closely with the [illegible] group.—H. F. Collins: On some crystallised sulphates from the province of Huelva, Spain. Analyses are given of pisanite, chalcanthite, coquimbite, copiapite, voltaite, roemerite, etc., from various pyrites mines. Experiments were made to determine the range of miscibility of iron sulphate and copper sulphate in mixed crystals of pisanite ($R''SO_4 . 7H_2O$) and chalcanthite ($R''SO_4 . 5H_2O$).—H. Hilton: The graphical construction of the constants of a shear. A graphical construction, based on the gnomonic projection, is given for obtaining the two circular planes of a shear, when the initial and final positions of two crystal-poles or edges are known.—H. Hilton: A note on crystallographic notation. A notation is suggested for the 32 crystal-classes and the 230 groups of movements, which is easy to write and print, and is based on the fundamental principles of structure-theory.—A. F. Hallimond and E. G. Radley: On glauconite from the Greensand near Lewes, Sussex; the constitution of glauconite. A boring through 325 feet of gault at Ford Manor yielded glauconite sand. A discussion of the analysis of this material and of some previously published analyses leads to the formula R_2O ($4R_2O_3$, RO) $10SiO_2 . nH_2O$.—L. J. Spencer: Ninth list of new mineral names.

DUBLIN.

Royal Irish Academy, June 12.—Prof. Sydney Young, president, in the chair.—G. H. Carpenter and Miss K. C. J. Phillips: The Collembola of Spitsbergen and Bear Island. The collections made by the Oxford University Expedition of 1921 include ten species of Collembola, one of which—*Folsomia sexoculata*—is an addition to the known fauna of Spitsbergen, while another—an Isotoma closely allied to the common *I. viridis*—taken on Bear Island is new to science. Twenty species of these insects have now been recorded from Spitsbergen, seven of these have been found also on Bear Island, which possesses, in addition, four species not yet detected on Spitsbergen. Sixteen members of this arctic fauna are represented in Great Britain and Ireland, while thirteen occur in Greenland and North America. Such distributional facts suggest paths of migration to the north of the Atlantic.

EDINBURGH.

Royal Society, June 19.—Prof. F. O. Bower, president, in the chair.—J. Stephenson: On the pharyngeal glands of the Microdrili (Oligochaeta). The chromophil cells in the anterior segments of the body of the Microdrili have, contrary to the usual view, no direct communication with the alimentary canal, and are not cells of the alimentary lining which have retreated from the epithelial layer while still retaining their connexion with it by means of a long thin neck which acts as a ductule. They are mesoblastic in origin; in the enchytraeids (where they form the septal glands) their secretion reaches the pharynx by percolating along special strands of tissue; in all other cases special channels are wanting and the products of the cells simply mix with the coelomic fluid; their secretion is thus an internal secretion.—W. Peddie: On self light, fatigue, inhibition, and recurrent visual images. Formal development of the trichromatic hypothesis is made beyond the stage at which it was left at the time of Helmholtz's death. Phenomena of contrast and after images, steadily decaying or oscillatory, and phenomena of fatigue and inhibition, are treated. The trichromatic theory of colour vision is founded securely on fact.—R. A. Fisher: On the dominance ratio. The "dominance ratio" upon which the relationship correlations depend, when inheritance follows the Mendelian scheme, has a numerical value [illegible] certain [illegible]. These [illegible] Mendelian [illegible] of the [illegible] correlations, in that it could occur only if the frequency ratio of the several factors were unsymmetrically distributed, in such a way that the dominant phase was commonly more numerous than the recessive phase. When, however, the effects of selection are taken into account the distribution of the frequency ratio may be calculated; the distribution obtained is unsymmetrical in the manner required, and the dominance ratio is exactly one-third. The distribution produced by selection also explains the occurrence among the non-recessives of the harmful character sometimes brought out by inbreeding.—A. P. Laurie: Chemical combination and Sir Alfred Ewing's magnetic atom. Sir Alfred Ewing's paper on hysteresis of iron has profound significance for the chemist, for it shows that it is possible to devise an atom of fixed and rotating magnets free from polarity, and that on the approach of another atom the rotating unit can be swung into an unstable position and then fall into a new stable position with evolution of heat. If we assume the electrons to be moving in the tiny orbits but arranged in space round a positive nucleus, the results obtained by Sir Alfred Ewing can be applied to chemical combination, ionisation, and catalytic action.

The Preservation of Food by Freezing.

CONSERVATION of our sources of energy is essential to national welfare, and the food stuffs whence human energy is derived are not the least important of our "fuels." Quite casual enquiry is sufficient to show that serious wastage of food constantly occurs. Markets are at times unable to absorb gluts of fish or fruit for which no cold-storage accommodation is available, and large quantities of these foods are consequently lost, while in the successive stages of transit from the abattoir abroad to the retailer at home, infection by putrefactive bacteria accounts for the loss of an appreciable proportion of our meat supplies. Such losses can be minimised by the development of the methods of cold storage and by a thorough scientific understanding of all that is involved in the refrigeration industry. This industry is now an essential characteristic of life in crowded communities; its expansion during the past forty years, enabling the supply of food to keep pace with the needs of a growing population, has been a remarkable achievement. The importance of the industry is magnified in the case of an island community, such as our own, whose supplies of home-grown food are strictly limited. In an industry of this importance a scientific stocktaking cannot fail to give valuable results.

The refrigeration industry makes wide demands upon the sciences. It calls for the co-operation of physicist, engineer, physiologist, chemist, botanist, zoologist, and mathematician for the solution of its problems. In arranging, through the Food Investigation Board, a joint attack upon the problems of food preservation from these different points of view, the Department of Scientific and Industrial Research is undertaking a most important function. To meet the needs a comprehensive organisation is necessary—if only to visualise the field for research—and since those needs are of vital national importance, it is fitting that the organisation should be initiated and supported by Government.

There has long been lacking a summary of our knowledge concerning the scientific aspects of cold storage, but it has now been supplied by Prof. Walter Stiles, who, at the request of the Food Investigation Board, has prepared a report upon the preservation of food by freezing.[1] We believe that this is the first general systematic study in this country of the scientific principles underlying the preservation of food in the frozen condition. For much of the information which follows we are indebted to Prof. Stiles's report.

[1] "The Preservation of Food by Freezing with Special Reference ..." By Walter Stiles. Special Report No. 7 of the Food Investigation Board.

Of the two refrigerative processes—chilling and freezing—employed for the preservation of food, the former is much inferior. In this process the temperature is kept at about 0° C., the physical state of the fresh material being maintained unchanged. In the freezing process, on the other hand, the temperature of storage is kept well below the freezing point of the food substance, which consequently becomes frozen into a solid block, the physical condition being profoundly changed. When it is remembered that, as a rough approximation, the velocity of a chemical reaction is halved by a fall of 10° C., it will be seen that the chilling process affords greater scope for the progress of the reactions incidental to putrefaction than does the freezing process. Moreover, the solid state of frozen tissue inhibits, or greatly reduces, the growth of micro-organisms and practically puts a stop to such putrefactive chemical actions as take place in aqueous media. While all foods can be preserved for a certain time by the chilling process, comparatively few are at the present time preserved by the freezing process. As Prof. Stiles points out, one of the objects of scientific investigation should be the transference of as many foods as possible from the chilling to the freezing process; and this was the object of many of the experiments of the Food Investigation Board which he describes. His report is restricted to the discussion of the processes and problems involved in the preservation of food in the frozen state. This method of preservation involves freezing, storage in the frozen state, and finally thawing of the frozen material, and the more nearly the condition of the foodstuff so treated resembles the original, the more successful has the storage been from the economic as well as the physiological standpoint.

In the freezing of foods the time of cooling is an all-important matter. It depends upon a number of factors, each of which Prof. Stiles examines in detail and indicates, by reference to the principles of physical chemistry, the extent to which they are controllable in the refrigeration industry. In foodstuffs other than liquids we are dealing with delicate and complex physical systems. True aqueous solutions of organic and inorganic substances and colloidal systems comprising both hydrosols and hydrogels are enmeshed in, or otherwise associated with, more or less definitely solid materials. Foodstuffs comprising such systems are obviously most susceptible to changing physical conditions, and it is only by careful study and control of the latter that successful food preservation can be ensured. The report directs attention to the gaps in our knowledge of matters of fundamental importance in refrigeration, such as, for example, the effect of rate of cooling upon the nature of sols and gels; in some cases the gaps have recently been filled by the work of Prof. Stiles [illegible] the interesting observation [illegible] a chlorophyll hydrosol is reversible [illegible] frozen the hydrosol yields visible "flocks" of chlorophyll, and the sol is not re-formed on thawing. Similarly he finds that the reversibility of the changes taking place in certain gels on freezing is largely dependent upon the rate of cooling, a gel which is rapidly cooled being reversible. Rapid cooling produces a fine-grained frozen mass, and, if this is sufficiently finely grained, the original structure of the sol or gel is restored on thawing. The statement may be extended to the freezing of plant and animal cells and tissues; such information as we have all indicates that, if these be frozen sufficiently rapidly, the changes in structure following freezing are reversed in thawing.

The essential importance of the vitamins for animal nutrition has made it necessary to ascertain the influence of low temperatures upon these accessory food substances. If the influence is markedly destructive, the nutritive value of foods must be seriously depreciated by cold storage. There is very little evidence upon this point at present, but it has been shown by Prof. A. Harden that the vitamin content of butter is undiminished by preservation in this way; investigations of the effect of low temperatures upon the antiscorbutic vitamins are at present in progress. Perhaps of little less importance than the vitamins are the enzymes in foodstuffs. Here more information is to hand. Generally speaking, enzymes survive exposure to the temperatures employed in refrigeration, and can exercise their catalytic functions when temperature and environment again become normal; in some cases, indeed, the catalytic activity may be increased by exposure to low temperatures.

Practically there are only two general methods employed in the freezing of foods on the large scale. These involve freezing in cold air, and in a cold brine solution, respectively.

Prof. Stiles's report includes a comparative account of the principles utilised in these processes. Air cooling is effected either by means of a system of cooling pipes placed inside the refrigerating chamber or by blowing into the chamber air which has been cooled outside by passage over a similar cooling-pipe system. Each method has obvious advantages and disadvantages, and the choice in any particular case will depend upon whether it is more important to reduce desiccation to a minimum or to avoid growth of micro-organisms. Fish depreciates rapidly by desiccation, but is not very liable to attack by micro-organisms; meat, on the other hand, does not lose water readily, but favours the growth of moulds.

The freezing of foodstuffs in [illegible] is a process

[illegible] It is to be found in the [illegible] specification of Hesketh and Marcet of 1899. The advantage of the method over that of air freezing lies in the much more rapid cooling that results, and rapid cooling, as mentioned above, is a characteristic of the most successful refrigeration. Brine is the only salt solution employed at present practice, but other salts, such as magnesium or calcium chloride, might conceivably be used. The process of brine freezing has its inherent difficulties; not only may the food cell contents pass outwards into the cooling medium, but salt may also pass from the latter into the tissues of the food. Penetration of salt into the food material is in some cases (*i.e.* fish) not objectionable, but in certain instances chemical action may occur between the foodstuff and the salt with undesirable consequences. Thus, while large pieces of beef frozen in brine were found to be in some respects superior to air-frozen beef, a reaction takes place between the salt and the pigment of the beef which so changes the appearance of the latter that its market value may be considerably reduced. The penetration of salt into the food substance cannot be prevented, but it can be minimised by a judicious selection of physical conditions.

The methods adopted for the storage of frozen food require the same careful consideration as those employed for freezing; the inherent difficulties are just as great. Physical changes, such as evaporation of water and aromatic flavouring substances, chemical changes including autolytic reactions, hydrolysis of fats and oxidation of the hydrolytic products, and finally the growth of moulds and bacteria, must be guarded against. All these changes can be retarded by lowering the temperature of the storage chambers, but economic conditions impose a limit at which reduction of temperature must stop. It becomes, once more, a question of selecting the least injurious conditions for each particular food; the conditions in storage chambers should, it may be emphasised, be different for different foods.

The use of liquid air on a large scale in the freezing and storage of food appears a remote possibility at the present time; but it is perhaps not entirely fanciful to picture a liquid air plant supplying nitrogen for use in the refrigeration industry and oxygen for other industrial purposes.

Prof. Stiles gives a brief summary of the available information concerning thawing of food. This side of the subject is not without importance, since the rate of thawing of frozen food has a significant effect upon its character.

A considerable proportion of the report is devoted to an examination of the relative merits of air freezing and freezing in salt solution in the case of both fish and [illegible]. The comparison, so far as the ultimate value of the food is concerned, is much in favour of the latter process. Parenthetically it may be added that Prof. Stiles does not deal with the economic side of the refrigeration industry. Despite its advantages and the fact that it has been known for a considerable time, the freezing of fish in a solution is a process which has only been employed during recent years, and on a small scale. Its chief advantages are the maintenance of weight, appearance, and general food value of the fish due to the reduced time of freezing and consequent minimised histological change. A quantity of experimental evidence obtained by the author and his co-workers under the Food Investigation Board, as well as by other workers in the subject, is collected in the report, and merits careful study by those who are concerned with the design and installation of food-preservation plant.

For the refrigeration of meat, freezing by immersion in brine has not yet been technically employed; the only process utilised is that of freezing in cold air. Beef which has been preserved in the frozen state is frequently inferior to fresh beef on account of the drip of meat juice which occurs on thawing. This loss may amount to as much as 15 per cent. of the weight of the meat. Consequently beef is, wherever possible, transported in the chilled condition; but since it cannot be kept in this state for more than three or four weeks, it is not possible to import chilled beef into the United Kingdom from Australia or New Zealand. From far distant countries beef must come "on the hoof" or in the frozen condition. Mutton, on the other hand, can be imported in the frozen state from the countries named in perfectly satisfactory condition. The discovery of a method of freezing beef which will obviate the difficulties mentioned is evidently a matter of importance, and the attempts made by the Food Investigation Board in this direction are of considerable interest. Small preliminary experiments indicated that rapid freezing by immersion in cold brine was an effective way of preservation so far as absence of drip and appearance and flavour of the product after thawing were concerned. Larger-scale experiments have not yet gone sufficiently far to yield conclusive results. One rather serious objection has already been mentioned. This is the discoloration of the surface layers of the lean of the meat owing to the conversion of hæmoglobin into methæmoglobin. The discoloration detracts seriously from the appearance and market value of the meat, but it is hoped that the cause, and a method of prevention, will be discovered in the course of further work. The successful application to beef of the method of brine freezing would lead to a very desirable expansion of our source of supply.

The Victorian Age

The Victorian Age: The Rede Lecture for 1922. By Dr. William Ralph Inge. Pp. 54. (Cambridge: At the University Press, 1922.) 2*s*. 6*d*. net.

IN choosing the Victorian Age as the subject of his Rede Lecture, Dean Inge afforded his audience ample occasion in which to enjoy the *obiter dicta*, which so frequently characterise his public utterances, and impart to them so piquant a flavour. It may be said the theme itself provided its opportunities. Its possibilities, in fact, of observations *en passant*, without a too obvious breach of continuity, are well-nigh limitless. The learned lecturer evidently revelled in the wealth and suggestiveness of his material, and the epigrams and aphorisms, at times, are almost coruscant in their brilliancy. Not that we would for a moment imply that the Dean's prelection in any way resembles the sermon of which King James remarked "that the tropes and metaphors of the speaker were like the brilliant wild flowers in a field of corn; very pretty, but which did very much hurt the corn." The richness of the soil which the Dean undertook to cultivate ensured the wealth and vigour of his crop; his flowers do but enhance the beauty of the field.

It may, however, be questioned whether the Dean's *obiter dicta* are always as sound as they are brilliant. For example, it is by no means invariably true that the pioneer starts by being unintelligible or absurd, has then a brief spell of popularity, and ends by being conventional and antiquated. The general character of the Civil Service in 1837 no doubt left much to be desired, but it is a travesty to say that it was "a sanctuary of aristocratic jobbery," and that its clerks were languid gentlemen with long whiskers, who, like Charles Lamb, departed early from their offices because they arrived late. The Dean occasionally is in danger of risking his credit for veracity by his irrepressible love of paradox and his affection for the epigram's peculiar grace, and for

"Some unexpected and some biting thought
With poignant wit and sharp expression fraught."

If, however, we make due allowance for the characteristic foibles of the lecturer, the Dean's brilliant survey of the significant features of the time covered by the reign of Queen Victoria is both illuminating and instructive. As he truly says, that period extended over the latter half of a *saeculum mirabile*, the most wonderful century in human history. His word-picture of England before what Toynbee styled the Industrial Revolution is done in his most characteristic manner. [illegible] we are told, was on the [illegible] a stake in the country. . . . Political [illegible] the hands of a genuine aristocracy, who did [illegible] deserve their privileges than any other aristocracy of modern times. . . . They were enlightened patrons of literature and art, and made the collections of masterpieces which were the pride of England and which are now being dispersed to the winds. . . . Those who have studied the family portraits in a great house, or the wonderful portrait gallery in the Provost's Lodge at Eton, will see on the faces not only the pride and self-satisfaction of a privileged class, but the power to lead the nation, whether in the arts of war or of peace"—a picture, in short, which will bring solace to the shade of that "Great Cham of Literature," the immortal Dr. Samuel Johnson. Not that the Dean can be truthfully described as a *laudator temporis acti*, for he is never wholly content with any age, and least of all with that in which he lives.

The whole account of the condition of England in the earlier years of the Victorian Age is tinctured with that flavour of mordant pessimism in which the Dean delights, and practically every phase and institution of the period comes under the gentle lash of his tolerant satire—its literature of complacency, the Platonism of Ruskin, the vehemence of Carlyle, the ugliness of the modern English or American town ("Never since civilisation began has such ugliness been created"); the gigantic blunder of the Industrial Revolution; the problem of mending or ending industrialism, foolishly called capitalism. ("Ruskin's own artistic life would have been impossible without the paternal sherry and the rich men who drank it; and Morris's exquisite manufactures depended absolutely on the patronage of the capitalists whom he denounced.") Departmental inefficiency; the systems of judicature; the slow emergence of the universities from the lethargy of the eighteenth century, "when they neither taught nor examined nor maintained discipline," when the Fellows "were most of them waiting for college livings, to which they were allowed to carry off, as a solatium, some dozens of College port"; the state of the army, "when a Royal Duke could not be given a military funeral, because there were not troops enough to bury a Field Marshal"; its glaring incompetence as revealed by the Crimean War, etc.

But the age had its compensations. The Dean is constrained to admit with Lecky that, at least so far as internal affairs went, no country was ever better governed than England between 18[illegible] and [illegible]. The one prime necessity for good [illegible]

[illegible] also paid the taxes were also those who imposed them. . . . Sound finance benefited the whole population by keeping credit high, interest low, and taxation light. Political life was purer than it had been, and purer probably than it is now. The House of Commons enjoyed that immense prestige which has been completely lost since the old Queen's death."

With regard to the intellectual and spiritual movements of her reign the Dean, if not exactly eulogistic, is at least more commendatory, and no part of his lecture affords more delightful reading, or exhibits sounder discrimination, than his account of the literary glories of the Victorian Age. As regards religion, he thinks it may be doubted whether organised Christianity has ever been more influential in England than during that period, "before the growth of the towns threw all the Church's machinery out of gear." At the same time, he admits that religious intolerance was very bitter, and only the secular arm stopped a whole series of ecclesiastical prosecutions. "Real hatred was shown against the scientific leaders, which Darwin calmly ignored, and Huxley returned with interest."

In parting with his subject the Dean, as might be anticipated, strikes no jubilant note. To him the Elizabethan and the Victorian Age appear as the twin peaks of English civilisation. But, he concludes, "as regards the fortunes of this country, the signs are that our work on a grand scale, with the whole world as our stage, is probably nearing its end." To which we can only fervently reply, *Absit omen.*

Natural History of Pheasants.

A Monograph of the Pheasants. By William Beebe. In four volumes. Volume III. Pp. xvi + 204 + pl. XLV–LXVIII + photogravure plates 40–60. (London: published under the auspices of the New York Zoological Society by H. F. and G. Witherby, 1922.) 12*l.* 10*s.* net.

THE third volume of this sumptuous work treats of the true pheasants—the genus Phasianus—and of the birds of the allied genera Puchrasia, Catreus, and Syrmaticus. Mr. Beebe has made an extensive study of the genus Phasianus, which embraces the most familiar and important birds dealt with in the monograph. His conclusions, based upon an exhaustive examination of numerous specimens, and his unique knowledge of the birds in their native haunts, are of outstanding importance.

In order to treat clearly of the group, Mr. Beebe has drawn a sharp line of demarcation between Phasiani [illegible] as they exist in their real zone of distribution, and the forms which have been crossed indiscriminately and acclimatised in all parts of the world. At least thirty-five forms have been described as species, or sub-species, or geographical races, according to the personal bias of authors; but in the evolution of these forms, mutation appears to have played little part, for most of them actually grade into one another, and even in their extremes are separated only by slight differences of colour and pattern. A good deal of individual variation occurs, especially in the more widely distributed forms, and this necessitates changing the status of species in this genus. The genus has usually included more forms than those recognised by the author, who, by consistently applying his criterion of genera—that of geographic non-overlapping—has removed the birds of the genera Syrmaticus and Calophasis from Phasianus, which is thus left "as an exceedingly homogeneous group."

In addition to a careful comparison of the numerous types and study of their environment, distribution, and barriers, Mr. Beebe has devoted much attention to the classification of the birds of this genus. Two very different lines of observation have contributed much to his ultimate decision. First, the results of a single day's collecting in China revealed, out of four brace of fully adult birds in freshly moulted plumage, several belonging to one covey, three recognisable sub-species, and two undescribed ones were obtained in two moderate-sized rice-fields. The second array of facts is derived from the conditions found among semi-wild hybrids introduced into foreign countries. Thus, at Tring, pheasants of colchicus, torquatus, and even of versicolor blood were turned down. Later a strain of pallasi was introduced, and from this mixture there arose pheasants which were absolutely indistinguishable from the wild form known as satscheuensis, the home of which is in the heart of China. From scores of similar facts Mr. Beebe has decided to consider every one of the continental forms of Phasianus as sub-species of *Phasianus colchicus.* The Japanese pheasant (*P. versicolor*) stands the test of a good species and is the most distinct of all the Phasianus group.

The distribution of the wild members of the colchicus group extends across Asia, from the Sea of Azof and the Black Sea eastwards to the Sea of Japan—a distance of nearly 5000 miles—and from Manchuria in the north to beyond the Tropic of Cancer. Throughout this wide area they have penetrated into valleys or along mountain slopes, sweeping through passes and adapting themselves to semi-arid deserts.

The typical form of the entire group, the common pheasant, the "Rion Caucasian Pheasant" of the

monograph, is a native of Caucasia, and is said to have been introduced into Europe from the banks of the River Phasis (now the Rion) in Colchis (now Kurtais). Though not mentioned by Mr. Beebe, the remains of Phasianus have been found in the Miocene of France and Switzerland, in the Pliocene of Greece, and in the Pleistocene of Germany—hence pheasants, possibly forms of colchicus, existed in Europe long before the advent of man.

With regard to the Koklass pheasants — genus Puchrasia—Mr. Beebe alludes to the difficulty of placing them with certainty in any linear scheme of classification. They show traces of resemblance to several groups, and perhaps come as close to the genus Syrmaticus, as defined by him, as to any other. The genus is one of the most interesting of the Phasianinæ, and its various forms reveal one of the rarest phenomena in nature—a widespread series showing delicately graduated and increasing complexity within a single closely related group of living creatures. Three species are recognised—*P. macrolopha*, *P. xanthospila*, and *P. darwini*, each with several forms.

The genus Syrmaticus, previous to Mr. Beebe's researches, contained a single species only—the gorgeous long-tailed Reeves pheasant, but here it has been expanded to include four additional species, namely, the copper pheasant, *S. soemmerringi*, comprising three forms; Hume's pheasants, *S. humiæ*, with two forms; Elliot's pheasant, *S. ellioti*; and the Mikado pheasant, *S. mikado*.

The Cheer pheasant (*C. wallichii*) exhibits a number of characters sufficiently distinct to warrant its inclusion in a separate genus, *Catreus*. It is confined to a comparatively small belt in the west and central Himalayas—Kumaon, Garhwal, and western Nepal—where it is found at elevations of 4000-10,000 feet.

In addition to the author's masterly treatment of the taxonomic aspect of the subject, he has added a charm to it by his graphic descriptions of the haunts and habits of the various birds which came under notice during his remarkable journeys, undertaken for observing and procuring specimens in various stages of plumage. He has also quoted copiously, when desirable, from the experiences of others. This combination of excellence, if it has ever been equalled, has never been surpassed in such a monograph.

The coloured plates, twenty-four in number, are reproductions from original drawings. Of these eleven are devoted to the principal forms of the true pheasants, and are from very careful drawings by the late Major Jones. The rest are the work of several well-known artists, among them Mr. G. E. Lodge, Mr. Fuertes, and Mr. Grönvold, but their reproduction is not so satisfactory as those which graced the preceding volumes. There are twenty-one photogravure plates depicting the haunts amid which the various forms are found and some of their nests. These are mainly from photographs by Mr. Beebe, and add much to the attractiveness of the volume. The maps, delineating the distribution of all the forms treated of are a very useful adjunct.

W. E. C.

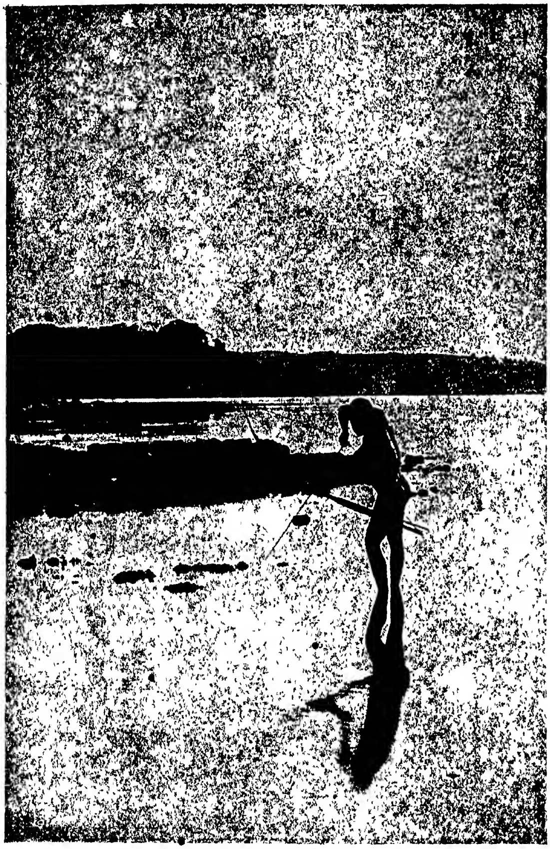
A New Book on the Andamans.

The Andaman Islanders: A Study in Social Anthropology. (Anthony Wilkin Studentship Research, 1906.) By A. R. Brown. Pp. xiv + 504 + 20 plates + 2 maps. (Cambridge: At the University Press, 1922.) 40*s.* net.

THIS handsome volume contains the anthropological results of a short residence of about eighteen months in the Andaman Islands on behalf of the "Anthony Wilkin Students' Research," and may therefore be taken as a sample of approved work by the modern type of Cambridge-trained student. It is well produced by the Cambridge University Press, and is excellently illustrated from photographs taken, it is presumed, by the author. Indeed, so good are these last that the present writer recognises the originals of several of the portraits. As regards photographs illustrating these aborigines, their surroundings, habits, manners, and customs, the scientific world is specially well off, owing to the efforts extended over many years by such competent illustrators as Messrs. E. H. Man and M. V. Portman, the many magnificent volumes of the latter observer, deposited in the India Office Library, being not nearly so well known as they should be.

The book may be divided into two parts: a running account of Mr. A. R. Brown's travels, giving the results of his observations of facts, together with references to and criticisms of his predecessors in this particular field of research, chiefly of Mr. E. H. Man, and an "interpretation" of the observations. The plan of the book is thus a good one. The writer states his own observations and where he differs from his predecessors, and then builds his theories on the results. It is where he ventures to differ from Mr. Man that the plan seems to fail to be as effective as it ought to be. He constantly sets up Mr. Man's views and statements only to knock them down. He thus pits his opinions against Mr. Man's. This makes for comparison, and leads to the observation that Mr. Man was thirty years with the Andamanese, knew them intimately and their language well, and studied them unremittingly: all this, too, at a time when they were numerous, their tribes well separable from each other, and the contact

with Europeans comparatively recent. Whereas Mr. Brown was with them for a short time, depended on interpreters, did not know the language except superficially, and only met them after they had been so decimated by epidemics that the tribes had had to drop their old exclusiveness and mingle freely together. It is true that Mr. Man was a pioneer who had to learn his way, and that Mr. Brown was a trained observer from the beginning, but all who know Mr. Man's work cannot also help knowing how meticulously and conscientiously careful he is in recording an observation of fact. It requires some boldness to differ from him on the point of accuracy. Several observers have tried, and not successfully. The result is that this latest book on the Andamanese, after all contains only evidence and not judgment. Mr. Brown is, here, nothing more than a witness—a good witness certainly, trained to his work—but only a witness, and the reader will have to decide for himself between him and Mr. Man.



An Andaman Islander shooting fish in Port Blair Harbour
From "The Andaman Islanders"

In the matter of recording language Mr. Brown has not been fortunate, though he has laboured hard. The older books and articles, from Mr. Man's works onwards, used an alphabet framed *ad hoc* by no less an authority than the late Mr. A. J. Ellis, whose skill, knowledge, and experience in such matters are still difficult to beat. The result has been that a good trustworthy system for recording these "unwritten" dialects for English readers has been in vogue for something like half a century. Mr. Brown has discarded it, and substituted the "Anthropos" Alphabet of Pater Schmidt. No one disputes the capacity of Pater Schmidt in this matter, but why in a book by an Englishman for English readers, published by an English University, go to an Austrian for the transcription of the language of the inhabitants of a British possession, when an adequate and well-known English transcription has been established for a long period, and has been used in many books? At any rate the result is not happy. Diacritical marks are used which are strange to English readers, though common enough in the Eastern European languages. The vowels are not familiar to users of English, and what are we to say of an observer who cannot detect the difference between "the *e* in error" and "*a* in Mary," and thinks they represent the same sound (p. 496). Or between the "*o* in not" and the "*o* in nought" (p. 496). Unhappily for Mr. Brown all four sounds are common in Andamanese, and he has thus put himself out of court as a recorder of languages, much more so as a critic of other people's work in this respect.

Like so many of his Oxford and Cambridge contemporaries, Mr. Brown reverts too often to a bad habit of the seventeenth-century writers on travel and foreign countries in ignoring the bibliography of his subject—in this case a long one—except to appropriate without acknowledgment the information gathered,

often laboriously, by even living predecessors. There are too many clear instances of this in his book.

Despite its drawbacks, however, the book supplies much good evidence on its subject, and the student will do well to make its acquaintance. With the second part one is not inclined to quarrel. It propounds a theory which cannot be gone into in a short review; but whether a theory stands criticism or not as time goes on, it is a good thing to put it forward, as the mere dissection of it promotes research and the acquisition of knowledge resulting from the research.

R. C. T.

Hydro-Electric Engineering.

Hydro-Electric Engineering. Vol. 1, *Civil and Mechanical.* Editor: Dr. A. H. Gibson. Contributors: H. D. Cook and the Editor. Pp. x+232. (London: Blackie and Son, Ltd., 1921.) 25s. net.

THE water resources of the world, from the point of view of available power for domestic, industrial, and agricultural uses, have received very considerable attention in recent years, and in many countries a large amount of information has been accumulated as to the amount of water-power that is available for exploitation. Not only have various sources of power, such as those of the great waterfalls, been harnessed, but in addition many schemes for impounding waters in suitable valleys and utilising them for power generation, irrigation, and for distribution to cities many miles distant have been carried into effect and at the present time many more are receiving serious consideration. In this country much has been done to impound waters for town and city purposes, but comparatively little has been attempted to develop the water-power available. Until the war came, with all its consequent economic problems, not least of which is the very serious increase in the price of coal, power could be produced by steam-engines and internal combustion engines at a price which made it practically impossible for water-power to compete, involving as it does large capital outlays per unit power produced and cost of transit over long distances. It is perhaps not surprising, therefore, that although Fairbairn and James Thompson in the British Isles were largely responsible for the very important developments which took place in water wheels and turbines in the nineteenth century, and the correct principles of design were very largely developed here and in France, yet neither of these countries have developed water-power as have, for example, Switzerland, Norway, and the United States. Students in Great Britain have not been encouraged to take a very keen interest in the subject and the literature published in this country has been somewhat scanty.

Recently, however, the Water Resources Committee, which has issued a number of reports, has investigated the power available in Great Britain, and a good deal of interest has been aroused in the possibilities of the development of hydro-electric power schemes. An equal interest has been awakened in other parts of the empire where the power available is much greater than here and where coal is not so easily obtained. This work on hydro-electric engineering comes, therefore, at an opportune time, for it is desirable that engineers and business men should understand clearly the principles underlying the storage and use of water for power purposes, and engineering students should have available a trustworthy guide in the study of the subject. A word of warning is required to those who hope to take a short cut to knowledge of the subject. In few branches of engineering have such diverse matters to be dealt with, and thus only those who are prepared by a sound training in engineering principles, civil, mechanical, and electrical, can appreciate fully and overcome the difficulties.

In the work before us, the authors have discussed some of the important principles involved but a great part of the work is occupied with descriptions and details of actual works. The all-important subject of the relationship of the water available to the rainfall on a given watershed, the power that can be obtained, and the problem of the flow of water and its measurement receive adequate treatment in the first third of the book.

The remaining portion of the book deals entirely with turbines. The various types are described with the aid of drawings of actual turbines, and the principles of design are discussed. It is of the greatest importance that the behaviour of turbines under variable conditions of gate opening and speed should be known, and typical characteristic curves are given for reaction turbines in which unit power is plotted against unit speed for various gate openings. Efficiency curves are also shown for turbines working under varying conditions of load. The Pelton Wheel is described and the theory discussed. The all-important question of the choice of the most suitable type of turbine for particular conditions is somewhat briefly referred to but the essential points to be considered are clearly presented.

An important chapter is devoted to speed regulation, and hydraulic problems connected with any attempt to change suddenly the flow of a large volume of water, and the theory of the surge tank are clearly discussed. Johnson's approximate formula for the movement of the water in a large tank for a given change of velocity

in the [illegible]. The danger of the period of oscillation in the tank synchronising with the governor is pointed out, and Johnson's differential surge tank, introduced to overcome this difficulty, is described. The concluding chapters deal with the general arrangement of stations and water-power reports. The text is clearly written and the illustrations are very good.

F. C. L.

Progress in Fat and Oil Chemistry.

Chemical Technology and Analysis of Oils, Fats and Waxes. By Dr. J. Lewkowitsch. Sixth edition, entirely revised by G. H. Warburton. Vol. 1. Pp. xviii + 682. Vol. 2. Pp. xii + 959. (London: Macmillan and Co., Ltd., 1922). 36*s*. and 42*s*. net.

THE successive editions of Lewkowitsch's "Oils and Fats"—now carried on by his successor, Mr. G. H. Warburton—are regarded almost as milestones by those engaged, in whatever capacity, in the industries based on these products, and their appearance affords a fitting moment for taking stock. It is perhaps of interest that the third edition was noticed in NATURE of September 22, 1904, p. 502, the fourth in the issue for August 19, 1909, p. 211, and the fifth in the issue for December 18, 1913, p. 449. The book is now of such size that this—the sixth edition—is like its predecessor, divided into three volumes of which only the first two have so far appeared. The index, unfortunately for the reader and the reviewer, is confined to the third volume, so that reference to these volumes is far from easy. We would strongly urge that this defect in so valuable a work be rectified in the future, as the temporary use of the first two volumes is impaired, and the reader in the future has to go to the labour of consulting two heavy volumes for the desired information.

Volume 1 as heretofore is devoted to the chemistry and analysis of the fats, a side which during the last decade has been relatively neglected. Volume 2, after an all too brief introductory section devoted to the obtaining of oils by the various methods of practice, deals in detail with the properties of the several oils. Volume 1 is described on the title page as entirely rewritten and enlarged, and volume 2, more circumspectly, as entirely revised. Both volumes, however, would be more properly described as revised, as little more has been done than to bring them up-to-date by the addition of new matter. No doubt in the remaining volume, which deals with a section of the subject in which very great progress has been made largely as the result of the altered conditions brought about by the war, much will have to be rewritten, but it is scarcely correct to apply this phrase to these volumes. From this point of view the new edition is frankly a disappointment; opportunity might have been taken to prune much which was diffuse and indefinite, and really to keep the work up-to-date in a crisp form. As it is, the reader at all versed in the subject will more often than not experience disappointment on consulting it, while for those who have the former edition the expenditure of a somewhat large sum on the new issue cannot be justified.

It is to be regretted that the study of the chemistry of fats and allied compounds is not at present fashionable amongst schools of chemical research, possibly in part because of the difficulty of the subject and the need to tackle it by what may be termed team work before results can be obtained. However this may be, the field of research is full of the most interesting possibilities both in the domain of pure organic, of physical and of biological chemistry. We may cite the work of Hardy, Adam, Langmuir, and others in this connexion, and the pioneer work on the synthesis of mixed glycerides commenced by Emil Fischer just before his death, with the hope that some of our workers will once more be attracted into this field of inquiry. Analytical work such as is embodied in volume 2 of the book is of interest technically, but the number of oils of prime industrial importance is limited to those which can be produced in quantity, and with sufficient regularity to make it an economical proposition to instal the requisite machinery to deal with them. Consequently, but few of the newer oils described become of practical interest: the world shortage of oils and fats so confidently predicted by the expert a few years ago has failed to materialise, so that there is no demand for new oils; indeed, to-day most of the vegetable oils are being marketed at prices unremunerative to the grower and manufacturer.

What is mainly wanted at the present time is far greater attention to quality: in this connexion it should be emphasised how little is known as to the manner of production of oils in plants, and the supposed change in the proportion of saturated to unsaturated acids in the oil during the ripening of the seed; also the cause of the development of fatty acid in the oil and its increase during storage. There is an opportunity for much research on the part of the biochemist in this direction.

The structure of a long open chain organic compound and the points of weakness at which it is most susceptible to attack is a question of prime interest to the chemist. The close packing hypothesis of Pope and Barlow, the modern crystal structure theory of the Braggs, and the recurrent spiral structure resembling a drawn-out coil of wire attributed to it of others, all have their adherents, and additional practical data are

most desirable. The hydrocarbons themselves are unsuitable for this purpose, but the fatty acids with their crystalline derivatives afford much more desirable material for research.

While in no way deprecating the enormous amount of information contained in the book, which virtually makes it an exhaustive dictionary, it is permissible to suggest that from the point of view of the user, a much more careful selection and limitation of the material would be an advantage.

E. F. A.

Our Bookshelf.

Die chemische Analyse. Herausgegeben von Dr. B. M. Margosches. VIII.-IX. Band: Methoden zur Untersuchung von Milch und Molkereiprodukten. Von Dr. Kurt Teichert. Pp. 374. (Stuttgart: F. Enke, 1909.) 11.40 marks (England: 45.60 marks).

On account of the interest now being shown in the quality of our milk supply, attention may be usefully directed to this book. It deals exclusively with milk and dairy products and forms the eighth and ninth volume of the general treatise on chemical analysis. The greater part of the space is devoted to the standard methods of analysis, but there is in addition a large amount of information which ought to be of help to the analyst and medical officer of health.

A preliminary section deals with the composition and properties of milk and the factors which are responsible for any change in the normal composition. Following this comes the portion which is concerned with the detailed analytical methods for the determination of fat, milk sugar, protein, etc. The chapter on cleanliness of milk and its freedom from bacterial contamination puts the facts in a clear and convincing manner, and is very valuable in view of the recognition of the dangers of uncleanliness both from the standpoint of public health and the manufacture of such products as butter and cheese. In this connexion the employment of the reductase and catalase tests has not become so general as was at one time expected, although the direct determination of dirt is now a regular practice in all analytical and public health laboratories, and leads to the punishment of those who dispose of filthy and insanitary milk.

Purely bacteriological methods of examination are shown to be difficult, particularly when applied to the detection of pathogenic organisms. The fermentation test, which is easily and rapidly carried out, is now being used to a greater extent both in connexion with the public milk supply and the cheese factory.

The chapter on the adulteration of milk, and the interpretation of the results of analysis obtained in this connexion, is valuable, as is also the one on the testing of cream, skim milk, whey, condensed milk, etc.

As in the case of milk, so with butter and cheese there are given details of analytical methods and hints on the interpretation of results. The detection of adulteration by the addition of foreign fats is dealt with, and other sections are concerned with the analysis of materials used in the preparation of cheese.

The volume is one for reference and the details appear to be scientifically sound.

Aeroplane Performance Calculations. By Harris Booth. (The Directly-Useful Technical Series.) Pp. xv+207. (London: Chapman and Hall, Ltd., 1921.) 21s. net.

The development of aviation appears to be entering on a new phase in which "safety in the air" is singled out as of primary present importance. This follows an era of military devotion to the cult of "performance," and the object of the book under review appears to be the statement of the detailed steps which have hitherto been taken to secure the greatest speed and maximum rate of climb of an aeroplane.

It is probable that the actual arithmetical processes described will rapidly fall out of use, but that the principles invoked will have a greater degree of permanence. The interest of the book is not so much in the relative merits of the four methods of prediction of aeroplane performance described in chapter 11. as in the statement of the problem as it appears to a designer. Much of the book shows the individuality of the author, but the general outlook is typically that of the community of aeroplane designers.

It is perhaps desirable at this point to indicate the established position as to aeroplane design and its relation to performance. The data used by all are common—derived mainly from sources external to the aviation industry—and have been used with almost equal success by a number of designers. In the result it is found possible to predict the consequences of the best efforts from preliminary sketch designs. To realise completely the maximum performance, it is necessary for a designer to consider the details of his craft carefully, and Mr. Harris Booth's book shows how that may be done. Further, it illustrates an essential element of progress, for it assesses in numerical form the importance of separate items in the complete whole. In illustration of this point, it will be found that 14 lbs. is estimated to be the resistance of a flying-boat hull if the open cockpits and hydroplaning steps are excluded. A further estimate shows that the steps account for 52 lbs. at the same speed and each cockpit for a further 17 lbs. Here is a striking example of the fact that the very small resistance of a smooth streamline body may be increased five- or six-fold by departures required for various reasons.

It is just because of its indications of the need for care in design that the present volume may fairly be accorded a place on the shelves of an aeronautical or design office library. So far as can be judged its importance is limited to such function, since the writer is following common practice in supposing that "performance" does not include "safety."

Building Contracts: The Principles and Practice of their Administration. By Edwin J. Evans. (The Directly-Useful Technical Series.) Pp. xviii+304. (London: Chapman and Hall, Ltd., 1922.) 10s. 6d. net.

The building trade resembles a good many others in that, while liberally supplied with works on the technical side, there is very little literature dealing with the business side. The present volume is intended to fill this gap. The subject matter is divided into four

parts, namely, the administration of contracts, office management, book-keeping, and trade memoranda. A glance at the table of contents will prepare the reader for some interesting information regarding what goes on behind the scenes. For example, among "methods usually adopted by contractors to obtain business" we find the following which refers to work undertaken on a percentage basis:—"It is surprising how many commissions of this character are secured by some contractors, and often well proceeded with, before their competitors are aware that the work is in operation. It must therefore be obvious that a good portion of the time and energy of these enterprising contractors is spent by keeping in touch with and studying the wishes and the requirements of architects and others who have work to place. These contractors are usually most obliging and amiable gentlemen who see no trouble in doing anything which will bring about business." The author is equally candid in many other matters, and it is impossible to read his book without feeling that he is intimately in touch with all the ramifications of his subject. The volume is a mine of information on all matters connected with the execution of building contracts, and will be of great value both to contractors and students.

Handboek der Algemeene Erfelijkheidsleer. By Dr. M. J. Sirks. Pp. x+494. ('S-Gravenhage: M. Nijhoff, 1922.) 15 gld.

TEXT-BOOKS of genetics have lately appeared with great rapidity. The most recent is that by Dr. Sirks, now before us. It is a substantial and well-illustrated volume, as good as its predecessors, covering the ground which has been explored up to date. The weakness of the book is that it attempts nothing new, whether by way of presentation or analysis. In a subject so new as genetics, something more than an exposition of easily accessible records should be demanded from a considerable text-book. The literature of horticulture and of animal breeding contains abundant material, both illustrative of established principles and suggestive of extensions, which has not yet been drawn upon. An author need be at no loss for novel themes of discussion, even if he has no actual discovery to present.

Dr. Sirks shows a disposition to limit his survey to the publications of the modern period and to subjects which have acquired topical familiarity. His treatment, moreover, is occasionally uncritical. The reader should have been told more explicitly that some of the interpretations, given as accepted doctrine, are highly speculative, and that some of the statements of fact are greatly in need of verification. Reports, for example, of the production of mutations as a direct consequence of changed conditions should not be accepted without a warning that, until the experiments have been repeated on an ample scale and confirmation obtained, evidence of this class has only suggestive value.

Manchester University Roll of Service. Pp. xvi+274. (Manchester: At the University Press; London: Longmans, Green and Co., 1922.) 10s. net.

THE Roll of Service of the University of Manchester contains 3765 names, of which 500 are those who lost their lives on service during the war. In each of these latter cases a brief account is given of the career including details of parentage, education, military history, distinctions, and particulars of death. In all, 842 distinctions were won, including two Victoria Crosses.

A preface to the volume has been written by the Vice-Chancellor, Sir Henry A. Miers. The record is very well arranged and produced, and serves as an adequate reminder of the service rendered by members of the University. It is also, to some extent, a memorial to those who laid down their lives in the common cause.

James Stirling: A Sketch of his Life and Works, along with his Scientific Correspondence. By Charles Tweedie. Pp. xii+213. (Oxford: Clarendon Press, 1922.) 16s. net.

MR. TWEEDIE'S volume opens with an account of the life of James Stirling, the distinguished mathematician of the early eighteenth century. Next follows a description of Stirling's contributions to mathematical knowledge, chief among them being his enumeration of cubic curves and the *Methodus Differentialis*. This latter is a remarkable piece of analysis, considering the state of mathematical knowledge at the time when it was evolved; it leads to the well-known expansion for log (n!) associated with Stirling's name. About three-quarters of the volume is occupied by copies of letters exchanged (during the period 1719-1740) between Stirling and such contemporary mathematicians as Maclaurin, Cramer, N. Bernoulli, Machin, Clairaut, and Euler. In days before scientific journals were developed new results were communicated by one worker to another in such letters as these. Much care has been expended by Mr. Tweedie in the reproduction of these letters: his book would have been improved by the addition of English translations of the French and Latin ones and by further comments upon them.

W. E. H. B.

Contemporary Science. Edited, with an Introduction, by W. B. Harrow. (The Modern Library of the World's Best Books.) Pp. 253. (New York: Boni and Liveright, 1921.) 95 cents net.

THE work under notice consists of a collection of twelve essays on recent achievements in various branches of science, by men who are masters in each. All are written in a way which makes them intelligible to readers whose special knowledge is not profound; yet even those who are engaged in advanced research may find interest in perusing them. This applies with special force to an excellent review of modern physics by Prof. Millikan. Though perhaps none the worse for the fact, the volume is a little unbalanced, articles of general importance being placed side by side with those dealing with such special topics as methods of gas warfare, the physiology of the aviator, and the measurement of brain-power. The inclusion of these is a reflection of the preoccupations of war time; and if their interest has waned, they serve to mark points in history. Atomic structure, engineering (Parsons), enzymes (Lister), duration of life, bacteriology (Flexner), psychoanalysis and Einstein, will serve as clues to the scope of the volume.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Cosmical Theory and Radioactivity.

SIR ERNEST RUTHERFORD in his book "Radioactive Substances and their Radiations" has suggested the possibility that solar heat may be supplied from radioactive energy derived from elements which had become radioactive under the extreme thermal conditions prevailing.

As possibly having bearings on cosmical theory (formation of nebulæ, planetary genesis, etc.) I would direct attention to the probability that such induced radioactivity would be attended with explosive phenomena on a very great scale and of extreme intensity.

Let it be assumed that in some deep-seated region of the sun the temperature has attained a potential critical for some element present—that is to say, adequate to disturb the atomic stability of this element. Now normal radioactivity results from internal atomic causes and the radioactive constant is statistical in origin, like a death-rate. But here instability is induced from without inwards. It seems, therefore, difficult to imagine that a normal radioactive constant can control the resultant effects. What will happen must resemble no mere death-rate based on statistics, but rather the mortality brought about by earthquake or flood. A large number of the specific atoms would be affected and a very great local rise in temperature would follow. There is, now, the further probability that this sudden rise will involve yet other elements in the catastrophe.

If this inference is justified, explosive phenomena in suns and nebulæ so far from being unaccountable must be regarded as inevitable, as being associated with gravitative attraction and the internal properties of the atom.

It is to be expected that such explosive phenomena would diminish in frequency and intensity as time advanced and elements of higher atomic weight became degraded. Thus, in primeval times, our sun may have been many times rent by such explosions. There appears to be evidence that central explosions of great violence occasionally occur even to-day.

How would the principle of the conservation of moment of momentum fare under conditions involving the translation of internal atomic energy into molar forms?

Trinity College, Dublin, July 9.

Gas Pressures and the Second Law of Thermodynamics.

IN the June *Philosophical Magazine* Mr. Fairbourne endeavours to prove that in certain easily attainable cases the second law of thermodynamics might be circumvented. He attempts to show that if an enclosure be divided by a partition, the chance that a molecule of a rarefied gas will pass the partition, from the space I to the space II, may be modified, by a funnel, without affecting the chance of passing from II to I, so that a pressure difference will arise. He considers the simple case, shown in Fig. 1, of a right-angled "funnel" in two dimensions only, truncated so that the diameter at the end BC is twice that at AD. Taking a point O on BC he shows that, of the molecules [illegible] on the whole more than half will [illegible] and less than half will pass through AD, since they can approach from an angle π while the angle between the limiting paths by which they can get through is in general less than $\pi/2$. He deduces that of 2N molecules striking BC in a given time less than N will pass through AD, while all of the N molecules reaching AD from the other side in the same time will cross it, so that on the whole more will come from II to I than *vice versa*.

The error in this argument lies in the fact that it is impossible to construct a line BC out of a number of points O; it is necessary to define the tolerance before one can say whether molecules have passed through O or not. As soon as this is done (by taking an element of length dl at O, and defining passage through O as passage through this length), it is clear that the chance of "passing through O" is not independent of the angle of incidence θ, but is proportional to $\cos\theta$, since dl is foreshortened for obliquely moving molecules. In any given case it will now be found that the total number of paths leading through AD is the same on both sides of the partition ZZ'. However, the following general proof of this equality should save the trouble of integrating particular cases. It applies to three dimensions and any shape of funnel.

It is clear that before the funnel (AB,DC) was added to the partition the chances of passing from

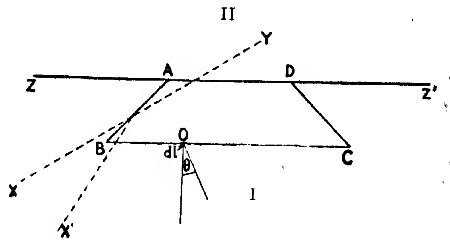

FIG. 1.

II to I and from I to II were equal, and that adding the funnel does not alter the chance of passing from II to I. If it is to have an effect then it must decrease the number of paths from I to II. But for every such path XY which it blocks it introduces a new path X'Y, and this is true of every point in any funnel. This result is of course well known in geometrical optics; if it were incorrect any temperature and energy density of radiation would be obtainable without work.

It may also be remarked that there is not only molecular roughness in even a polished wall, but thermal agitation of all the molecules of the wall; the argument that if the wall reflects light it should "reflect" a molecule is vitiated by the fact that the wave-length of visible light is about a thousand molecular diameters; and the argument that even if the direction of rebound is fortuitous the funnel should have an effect defies elementary hydrostatic theory.

Lastly, the mean free path of the molecules is irrelevant. Mr. Fairbourne assumes that his theory would not apply if there were a large proportion of encounters between gaseous molecules; but it is clear that if the effect of the funnel is to give on the whole a bias away from II to the average molecule striking it, it cannot matter whether that molecule retains the bias or hands it on to another [illegible]

The effect, if there were one, should be proportional to the number of molecules striking the funnel per second, *i.e.* to the total pressure.

R. D'E. ATKINSON.
Clarendon Laboratory, Oxford, June 1.

IN reply to Mr. R. d'E. Atkinson's letter, I should like to point out that, while his conclusion is undoubtedly true with regard to light, it is by no means clear that analogy justifies his extension of this conclusion to the molecular problem under consideration in my paper. The fundamental conception of unchanging uniform concentration would appear incorrect when applied to particles proceeding between collision centres and entering a minute vessel, the diameter of which is considerably less than the mean free path of the gas concerned. This confusion of issue, introduced by regarding the problem of light as identical with that I was considering, may perhaps be brought out most clearly by the following calculation, which is almost identical with the one Mr. Atkinson suggests would be possible.

If ABCD (Fig. 1) is the figure dealt with in the paper, and DH, AF, PE all be inclined at angle α to BC, while DI is perpendicular to BC, and D′ is the

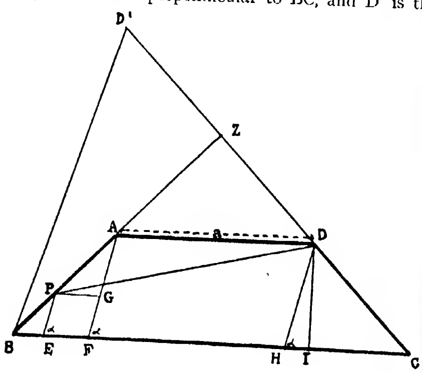

FIG. 1

mirrored image of D with respect to BZ, P being the point on BZ such that angle EPB is equal to angle DPA, then the following relationships may be calculated.

Case 1, where α is not less than angle D′BC. By the usual laws of reflection, light approaching BC from below, approximately at angle α, must pass out at AD if it enters between E and H, but will be returned through BC if it enters either between B and E or between H and C.

$$EH = EF + FH = PG + a = a\cot\alpha + a.$$

Case 2, where α is not less than angle DBC, and is not more than angle D′BC. In this case only light entering between B and H will escape through AD.

$$BI = BI - HI = \tfrac{3}{2}a - \frac{a/2}{\tan\alpha} = a(1\tfrac{1}{2} - \tfrac{1}{2}\cot\alpha).$$

Case 3, where α is less than angle DBC. In this case all the light will necessarily be returned through BC. Where α is greater than a right angle these three cases are merely duplicated.

Hence, if equal light intensity in all directions be assumed, and if A be taken as a constant representing its uniform concentration, then the ratio of the amount of light which passes from AD to BC to that which passes from BC to AD in unit time must be

$$A\int_{\alpha=0^\circ}^{\alpha=90^\circ} a\sin\alpha\,.\,d\alpha$$

$$: \left\{ A\int_{\alpha=\angle D'BC}^{\alpha=90^\circ} (a + a\cot\alpha)\sin\alpha\,.\,d\alpha + A\int_{\alpha=\angle DBC}^{\alpha=\angle D'BC} a(1\tfrac{1}{2} - \tfrac{1}{2}\cot\alpha)\sin\alpha\,.\,d\alpha \right\}$$

$$= Aa : \left\{ Aa\int_{\alpha=\angle D'BC}^{\alpha=90^\circ} (\sin\alpha + \cos\alpha)\,d\alpha + Aa\int_{\alpha=\angle DBC}^{\alpha=\angle D'BC} (1\tfrac{1}{2}\sin\alpha - \tfrac{1}{2}\cos\alpha)\,d\alpha \right\}$$

$$= Aa : Aa\,(0{\cdot}643 + 0{\cdot}357), \text{ approximately},$$

$$= Aa : Aa.$$

The above integration to equality is essentially dependent upon the axiomatic acceptance of the unchanging existence of equal concentrations for

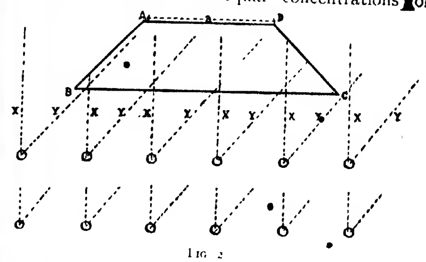

FIG. 2

intensities in all directions, uniformly throughout the medium in which the cone is placed. Such unchanging uniformity of concentration might be presumed to exist in perfectly diffused light, but it cannot exist in gases, since changes of concentration occur as intermolecular collisions, and must be important in relation to the entering of vessels considerably smaller than the mean free path of the gas. The light problem is one of flow, the molecular problem may be regarded as one of (interrupted) oscillation, at least to a large extent.

If each of the little circles in Fig. 2 be taken to represent equal areas (or spheres if three dimensions are being considered), the probability of molecules proceeding outwards, from collision in one of these circles, along a path X, is equal to that of their proceeding from collision, in that same or any other equal circle, along a path Y, this being true however many circles are under consideration, even in the limit of their occupying the whole space within free path distances from the cone. If two directions, X and Y, are considered for a large number of such circles, regularly placed so as to be representative of the equal probability of collision in all parts, it is obvious that molecules approaching BC along directions X

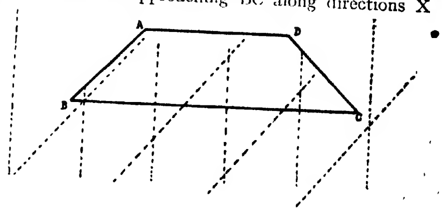

FIG. 3

and Y, and starting from collision sources, do not cross BC in numbers proportional to the sines of the angles of these paths with BC, as has to be assumed in light calculations such as the one above, which may be illustrated by Fig. 3 where no collisions occur,

and where the light approaches in two regular streams of equal concentration. The difference is due to the position of the opening BC relative to collision centres below it within less than free path distances, from which the approaching molecules will start, with equal probability of movement in all directions. The molecular problem would thus appear to approximate to the simple statement in my paper, in which the "points O" may consequently be regarded as little elements of area, and to be quite different from light calculations such as the one worked out above.

In connexion with Mr Atkinson's claim that elementary principles would be defied if an effect were to occur, it is not obvious why this should be so (provided, as has always been emphasised, that the apparatus shall be sufficiently small to deal with the oscillations or movements of molecules individually), any more than in the case of the energy of a swinging pendulum being converted into useful external work by the agency of suitable mechanism

The argument that if light is reflected, then molecules must actually be so similarly, to which Mr. Atkinson strongly objects, does not appear in my paper, where, in fact, the exact opposite is stated (page 1053, line 26), although such reflection, as an average effect, is not regarded as being impossible.

Polarisation of Diffused Light under the Sea.

I took advantage of a recent opportunity to make some observations on polarisation of the diffused light in sea-water, using a detector consisting of four quartz prisms made up on the De Senarmont principle, combined with a Nicol. The depth was 30 feet, the sea-water very clear, and the day cloudy, with no trace of sky polarisation. The diffused light at the bottom was quite strongly polarised, the water behaving like a turbid medium observed at right angles to the incident beam, the plane of polarisation being perpendicular to the surface.

The greatest intensity was in the horizontal direction, diminishing rapidly as the angle of elevation increased, and disappearing completely long before the direction became nearly vertical. Repeated observations created a strong impression that the direction of maximum polarisation was not exactly horizontal, but very slightly inclined downwards. However, the difference, if any, was so small that it must be regarded as doubtful

I should have liked to repeat observations on a day of blue sky, but the opportunity did not arise. The light from the sandy bottom and from a white plate did not show any trace of polarisation.

Apart from polarisation, it was interesting to observe the surface. It is not easy to look vertically upwards in a diver's helmet, but there was evidently a circular luminous area directly overhead, rapidly falling off in intensity without any sharpness of transition. It was a kind of inverse penumbra effect.

E. E. Brooks.

Leicester City Technical School, June 30, 1922.

Discoveries in Tropical Medicine.

In Nature of June 24 Sir Ray Lankester repeats his statement that the transmission of *Filaria bancrofti* from infected to healthy men through the intermediation of the mosquito is not a sufficiently established fact. I trust you will permit me to state, for the benefit of those of your readers who may be puzzled by an assertion so discordant with current teaching, that at this school we shall always be happy to demonstrate sections of mosquitoes and of *human* lymphatic gland that show the facts of that transmission.

With regard to Sir Ray Lankester's other emphasised statement that "Manson did *not* discover the part played by the mosquito" in this transmission, we shall be happy to show Manson's original charts and drawings made in Amoy, and other necessary evidence that Manson did follow out the development of the embryonic and larval *Filaria bancrofti* in the stomach and body-cavity of the mosquito. This evidence, quite apart from any additions to it or corrected inferences from it, establishes the essential fact that the insect is the vital agent of transmission, since it releases the imprisoned embryo from the blood-vessels of its host, nourishes it until certain necessary organs are developed, and thus enables it to make a start in life.

Ouramœba.

With regard to the notes by Messrs. Rowley and Kirkpatrick in Nature of July 8, on the occurrence of Leidy's genus Ouramœba in England, it may be of interest to record that I have recently (a few days before their letters were published) found one specimen of *Amœba proteus* in this condition, *i.e.* infected with a parasitic alga. I was very much interested, because I have never encountered anything like Ouramœba in the neighbourhood of Manchester, where I have chiefly collected.

I have not Leidy's book with me now for reference, but am familiar with his figures, and have no doubt whatever that the specimen which I found corresponds exactly with his genus Ouramœba. It was a typical *Amœba proteus*, with filaments of the parasitic alga projecting fanwise in two tufts, one tuft on each side, nearer the end which was posterior in progression. Its vitality certainly was not impaired in any way.

This specimen was taken from a small tarn near Crag House farm, not far from Windermere. The tarn lies at the summit of a ridge, the altitude of which is given as 700 feet on the Ordnance Survey map It should be emphasised that, although the tarn contains ordinary *Amœba proteus* in fair abundance, only one specimen has so far been seen which was infected with the alga. The other fauna of the tarn include very numerous Thecamœbida, some Flagellata, Ciliata, desmids, diatoms, etc., a fauna which corresponds fairly closely with that dealt with by Leidy in his book, and which is probably typical of open moorland country at high altitudes.

Amœba proteus is found in other tarns in this neighbourhood; but I have never seen any other specimen infected with the alga from these other localities, although, since reading Mr Rowley's letter, I have again searched fresh material.

Histological Stains.

With reference to Dr. Nierenstein's remark (July 8, p 33) that the British dye industry would do well to pay attention to the supply of dyes suitable for histological work, it should be recorded that in 1919, when pathologists here had a difficulty in getting satisfactory stains, the Pathological Society of Great Britain and Ireland approached Dr. Levinstein in the matter and received from his organisation ample and most useful help which carried us on until reasonably good stains became available again through the ordinary trade channels.

A. E. Boycott.

July 8.

The Structure of Organic Crystals.[1]

By Sir William Bragg, K.B.E., F.R.S.

It may be said with truth that modern advances in physical science are due in the main to the acquisition of the power to handle the individual atom. Until the present time we have always attacked the problems of matter by examining the behaviour of atoms or molecules in groups. The new powers arise in two ways:—

In the first the individual atom is endowed with excessive speed and energy, and is able to make its individuality felt on this account. The α-particle of the radioactive radiations is a helium atom moving with a speed of the order of one-tenth of that of light. While in possession of the relatively tremendous energy which the speed implies it can, unaided, make a visible impression on a fluorescent screen. It can pass through thousands of other atoms without sensible deviation and, if occasionally it suffers violent deflection, it has penetrated to the very core of the atom which has deflected it. Rutherford has shown us what important deductions can be drawn as to the construction of the atom by examining these rare and sharp deviations, and is going even further in examining the shattering effect which the deflecting atom may itself experience. So also, the electron endowed with sufficient speed can traverse matter and bring about its ionisation and other effects of great interest, but if its velocity becomes less than one million metres per second this free existence disappears. It is attached to the first atom it meets.

The second method of attack upon the individual atom proceeds on very different lines. It is by way of the mutual action of X-rays and crystals. When we are examining things by eyesight we follow the influence of the objects that we look at upon the waves of light. If we wish to penetrate deeper into the minute, we take advantage of the optical effects of lenses and build microscopes: but, even then we cannot attack individual objects containing less than many thousands of individual atoms. A limit is set by the difficulty that light cannot show us the form of things which are much smaller than the wave length of the light itself. With the aid of the very short waves known as X-rays we can make our way down to objects ten thousand times smaller, but by itself this extension of our powers would be inefficient, because the effect due to one atom or one unit of pattern would be inappreciable. Here lies the value of the crystal, which, being an aggregate of some small atomic pattern repeated again and again through space, shows up on a measurable scale the properties of the atoms in the single unit. By the combination of X-ray and crystal we can examine the very foundations of material construction. It is difficult to set a limit to what may be the consequences of the exercise of these powers since we can now examine all physical effects, so to speak, at their source, and must in the end be able to refer all the physical and chemical properties of materials to the properties of the individual atoms and their mutual forces. So far the new methods have scarcely begun to show their full strength. A few inorganic crystals have been examined with a view of discovering their structure, but the new field of research is barely entered. Inviting roads lie before us pointing in numerous directions.

Very little has yet been done in the way of applying the new methods to the structure of organic crystals, although no study could be more tempting. Their vast variety of form, the perfection of their structure, their importance, all urge us forward, and especially the fact that the whole progress of organic chemistry shows that the science depends upon laws of position with which the X-rays are especially qualified to deal. The difficulty at the outset lies in the complexity. In the naphthalene molecule there are 18 atoms: in what way can we expect by means of X-rays to solve the intricate problem of their relative positions? Our first attempts to solve inorganic crystals depended for their success upon two facts:—

The first, the simplicity of the structures which were attacked.

The second, the guidance derived from the principles of crystallographic symmetry.

The determination of the structure of rocksalt opened a way to further determinations of such simple crystals as the diamond, zinc blende, fluorspar, and others. In all these the principles of symmetry supplemented the knowledge derived from the examination of the intensities of X-ray reflection by the various crystal planes. As the work has proceeded in the hands of observers in many countries, other principles have emerged or are emerging which render further and very valuable aid so that problems appear to be coming within our grasp that not long ago seemed most difficult of solution.

Of these principles, one began to appear in consequence of the very earliest results. It was a very striking fact that in crystals of polar substances the molecule seemed to disappear; it was in fact dissociated, and the structure of the crystal depended upon the grouping of the positive ions round the negative and of the negative ions round the positive. In rocksalt each metal atom is surrounded by six atoms of chlorine and *vice versa*. If we accept this as an indication of the general character of such structures, adding to it the condition that every atom is to be like every other atom of its own kind in respect to relative distances and orientations of all its neighbours, it becomes possible to foretell the probable form of structure, using the X-ray methods for subsequent verification. This method of proceeding may be very much easier than if it were taken in the reverse way. We might for example have gone far to foretell the structure of fluorspar. It is an ionic compound in which the calcium atoms are doubly charged and fluorines are singly charged. Each positive is to be surrounded, therefore, by twice as many neighbours as each negative by positive. The fluorspar structure in which the metal atoms are arranged at the corners and the face centres of the cube, while the fluorines lie at the centres of the eight small cubes into which the larger ones can be divided, is one of the very few regular ways in which this numerical relation of 2 to 1 can be carried out. So also in ice, the 2 to 1 arrangement is

[1] Discourse delivered at the Royal Institution on Friday, May [illegible]

carried out in a second of these ways, the relative numbers of neighbours being four to two. It is the lightest and most open of the 2 to 1 structures, and is consistent with the low specific gravity of ice and with the possibility of compressing the substance into denser forms: at the same time it shows the six-pointed arrangement and the featheriness of the snow crystal.[2]

The earlier results at the same time showed that in the diamond we had a construction of very different properties and nature. Here the atoms are electrically neutral and are bound to one another, not by electrical attraction from centre to centre, but by a more intimate process which probably consists in some way of a sharing of structural electrons. The diamond is on this account the hardest of known substances.

These considerations amount to a recognition that the bonds between the atoms may be of very different characters though it may be difficult to draw hard and fast lines between them. We can say that there is a very strong electron sharing bond of which the diamond is typical, and that there are ionic bonds in polar compounds which in general are of a weaker character, as, for example, in rocksalt, though on the other hand they may be strong when, as in the ruby, the ionic charges are large.

Lastly, there is a third type, which is found in the organic crystal, where it would appear that the separate molecule can be distinguished. The atoms in each molecule are strongly tied together, but the forces that bind molecule to molecule may be described as residual. They would appear to be weak fields concentrated at definite points on the molecule, the positive and negative charges to which they are due lying within it.

The second principle which emerged fairly early in the experiments was described by my son in an address which he gave in this Institution some time ago.[3] We may call it the principle of radii of combination. The distance between the centre of one atom and the centre of a neighbour can in many cases be measured with great accuracy: we can compare these distances when substitutions are made in isomorphous compounds. The replacement of fluorine by chlorine, chlorine by bromine, bromine by iodine in a series of salts produces changes in the distances which imply that the radius of any one of the atoms mentioned may be treated as a constant within the range of the substitution considered. The accuracy is amply sufficient to give useful assistance in crystal analysis. It would not be true, however, to say that each atom has an invariable radius, and indeed the original statement of the principle purposely refrained from going so far. It is not right to speak of *the radius* of an atom; it is better to speak of *a radius of combination*. We may take an illustration from the behaviour of arsenic, antimony, and bismuth. The crystals of these substances are trigonal in form,[4] plainly showing that the properties of each atom are not the same in all directions within the crystal: in fact, analysis shows that each atom is fastened to three on one side of it by much closer bonds than to three atoms on the other side. One bonding resembles more closely that of the diamond, the other that of a metal where free electrons keep the atoms together by electrostatic attraction. It may be said that the atom behaves as a metal on one side and a non-metal on the other. At any rate, there are two radii of combination varying with the nature of the bond. The metallic bond is the weak one and the cleavage plane cuts only through such bonds. It seems very likely that in this way we can understand the formation of crystals of different type when these elements enter into their composition. For example, in the cubic form of senarmontite (Sb_2O_3) the atoms of antimony are completely separated; each touches six atoms of oxygen, while each oxygen touches four atoms of antimony. Antimony is here behaving as a metal only, so that we represent it in a model as a sphere, and the uniform spheres of antimony and of oxygen naturally build into a simple crystal. It is a cube in which the atoms of antimony occupy the corners and centres of the faces while the six oxygen atoms lie at the centres of six of the eight small cubes into which the large one can be divided.

There is, however, an alternative form of Sb_2O_3 known as valentinite, which is ortho-rhombic. Analysis, so far as it has gone, though it is not yet complete, points emphatically to the conclusion that here atoms of antimony are pairing, the bonds between the members of a pair being of the stronger variety already referred to. We now have an elementary body of a dumb-bell shape which, when forming part of the crystal structure, will naturally cause a deviation from a simple cube.

Yet again, there are principles which are barely established as yet, though it seems probable that they will be found of material assistance in analysis. The greater expansion of some crystals in certain directions than in others seems to depend upon the nature of the bonds. Bismuth expands more along the axis than across it, as we might expect from the fact that in the one expansion the weak bonds alone can be operative. In the same way diamond has an extremely small expansion co-efficient because all the bonds are of the strongest kind, but in graphite, on the other hand, the expansion along the axis may be described as enormous. Mr. Backhurst finds an increase in length of 3 per cent. for a rise of 900° C. At the same time, so far as can be inferred, the expansion across the axis is still quite small. In one case weak bonds only are concerned, in the other, strong bonds of the same kind as in the diamond.

It is when all these considerations are taken into account that it seems possible to make an attempt upon the structure of the organic crystals. They are, of course, very complex; naphthalene contains 10 atoms of carbon and 8 atoms of hydrogen, and our ability to interpret X-ray evidence, that is to say, the relative intensities of reflection by the different planes in different orders, is not sufficiently advanced to enable us to place so many atoms in their proper position in the cell from this evidence alone. We can readily find the size of the unit cell, show that there are two molecules in it, and that the points, each of which represents a whole molecule, are to be placed as is shown in Fig. 1, but without some further help we can frame no hypothesis on which to proceed.

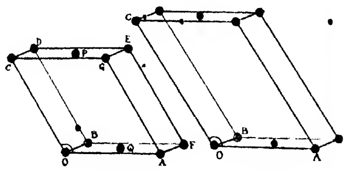
Suppose now that we compare the structures of diamond and graphite. As my son showed long ago,

[2] Proc. Phys. Soc., London, vol. xxxiv. pt. 3, p. 98.

[3] See *Phil. Mag.*, Aug. 1920.

[4] James and Tunstall, *Phil. Mag.*, Aug. 1920 and July 1921; Ogg, *Phil. Mag.*, July 1921.

the structure of graphite must be derivable from that of the diamond by separating to nearly double their previous distance the sheets of atoms parallel to one of the cleavage planes of the latter crystal. The question has been very carefully considered more recently by Hull in America and by Debye and Scherrer on the Continent in the hope of finding more exactly the details of the movement: they do not quite agree.



Naphthalene. Anthracene

FIG. 1.—Unit cells of naphthalene and anthracene drawn to the same scale

	OA = a	OB = b.	OC = c
Naphthalene . . .	8·34	6·05	8·69
Anthracene . .	8·7	6·1	11·6

Naphthalene α = BOC = 90°, β = COA = 122° 49′, γ = AOB = 90°
Anthracene α = BOC = 90°, β = COA = 124° 24′, γ = AOB = 90°.

Fig. 2 represents the change as described by Hull. The bonds between the atoms in each sheet are unaffected apparently, but those between sheet and sheet are replaced by something much weaker. The diamond is typical of hardness, the graphite is used as a lubricant. If the hexagonal rings of which the sheets are formed have survived this violent change, why not suppose that they may survive the further change when the sheets break up into ring structures? In other words, suppose that the benzene ring is really a fact, not merely a diagram; the distance between atom and atom in

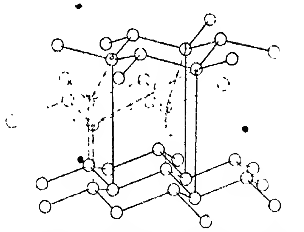


FIG. 2.—The fine lines of the diagram show the structure of graphite. By moving the top layer to the position shown by the broken lines the diamond structure is obtained.

the ring is 1·54 Å.U. as in the diamond, and perhaps we may add that the atoms are not all in one plane, but are arranged, as may be seen in Fig. 3. We then proceed to test this hypothesis by finding whether we can fit together molecules of the assumed size and shape into the cells which hold them. From X-ray studies we know the exact form and dimensions of the cells, and can learn also much concerning the relative distributions of the molecules within them. It appears at once that in the few simple cases which have been examined an excellent fit is possible and, more than that, we find encouraging signs that the structural idea has been chosen rightly. For instance, the comparison of the cells of naphthalene and anthracene, one a two-ring, the other a three-ring combination, shows that two of the axes of the cell remain constant, while the third has grown by an amount which is nearly the width of the benzene ring. From these and various other indications we build a structure such as is represented in Figs. 3 and 4. It would seem that the molecules are linked together side to side more strongly than from end to end, and that is why these and similar crystals cleave across the end or β position.

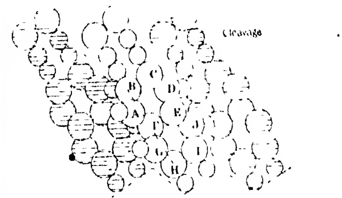

FIG. 3.—Showing mutual relations of three naphthalene molecules and parts of others.

The unshaded circles between the two cleavage planes represent a molecule as at Q (Fig. 1). The shaded represent molecules B and F in the same figure. The small circles represent hydrogen atoms, but their size is uncertain.

Diameter of carbon atom = 1·50. BH = 4·92. Projection of AD on the plane of the diagram = 2·50. Benzene ring consists of atoms A . . . F only.

If we examine α-naphthol in which hydrogen at the side of the naphthalene molecule has been replaced by an OH group, we find that the standard cell contains four molecules, which is what we should expect, for each of the four α positions must be represented. When the OH group is taken from the side and put at the end, we find that the cell has shrunk sideways and grown lengthways by the amount we should expect to result from the addition of an oxygen atom. When as in acenaphthene a complex group of atoms is attached to one side of the molecule and the crystal

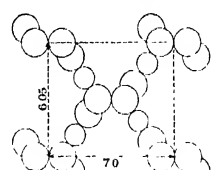

FIG. 4.—Section of naphthalene cell perpendicular to the axis of c, showing α-hydrogens connecting the molecules side to side.

to our surprise becomes more regular than before, right angled instead of oblique, we find an explanation in the fact that there are now four molecules within the cell instead of two, and that by sloping in pairs in opposite ways they increase the symmetry of the crystal.

These examples may serve to show how an attempt may be made to arrive at a knowledge of the structure of these organic compounds with, I think, some success. It seems justifiable to see in the rigid and queerly shaped molecule attaching itself at definite points, and with great precision of orientation to neighbouring molecules, a cause of the immense multiplicity and, at the same time, the accurate form of organic crystals, and indeed to find here the foundations of organic chemistry.

The Action of Cutting Tools.

By Prof. E. G. Coker, F.R.S.

ENGINEERING activity is so largely dependent on the action of cutting tools, that it is not surprising to find a very large amount of research work has been devoted to its study, and at the present time there are in England two committees actively pursuing researches in this field, in addition to private investigators. At the suggestion of the Cutting Tools Research Committee of the Institution of Mechanical Engineers, of which Sir John Dewrance is chairman, some experimental studies of a preliminary character have been made recently at University College, London, on transparent bodies subjected to the action of cutting tools, and the double refraction produced by stress has been used to measure the stress distribution in the cut material. Similar experiments have also been carried out on some glass-cutting tools used for turning and planing operations.

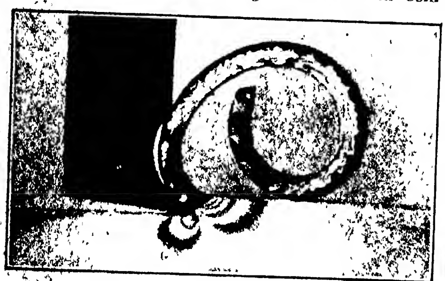

Fig. 1.—Steel tool planing a strip of nitro-cellulose.

The photo-elastic method has many advantages over direct experiment on metals, as up to and, in fact, well beyond the elastic limit of the transparent nitro-cellulose used, the stress distribution produced can be measured with considerable accuracy at all points in a disk or flat plate under the action of a tool. The optical effects give, at once, a measure of the difference of the principal stresses at a point, the lateral contractions afford a measure of their sum, and the isoclinic lines map out the directions of the stresses. Existing literature shows how very difficult it is to obtain similar information from the metal itself when under the action of a tool. Since the distributions are similar up to the elastic limit of each material, owing to the absence of elastic constants in the fundamental equation $\nabla^4 \chi = 0$, there are obvious advantages in a study of the characteristics of cutting tools by these means. The general phenomena observed when a tool is cutting are shown in Fig. 1, where a steel tool is planing a plate of nitro-cellulose in a circularly polarised field of light. It will be observed that colour bands spring from the cutting edge of the tool and curve round in approximately circular arcs to meet the boundary, indicating the existence of variable radial compressive stress in the area in front of the tool, and a similar state of tensional stress behind it.[1] Measurements of the principal stresses and their inclinations show that this is approximately what obtains, and a very fair idea of the stress conditions in the material can be obtained from the photograph if radial lines are drawn in all directions from the point of the tool to intersect the colour bands. The outer bands pass through all points at which the stress is 1150 pounds per square inch, for the sharply defined boundary between the purple and the blue, and the succeeding ones reckoning inwardly mark stresses of twice and three times this value. The fourth band indicates possibly a somewhat different stress intensity than its numerical order warrants, owing to its close proximity to the black area in which intense plastic stress is developed at and near the cutting edge of the tool. An interesting feature is the partial recovery of the material, for the black area is met with only at this place. The shaving again shows brilliant colour effects after it has finally left the tool, but later becomes obscured, again owing to the further curl developed due to contact with the parent material.

Careful measurements show, however, that the actual state of stress, excluding the plastic field, is somewhat more complicated. The stress is never quite radial, and the isoclinics are therefore not straight lines, but are always curved somewhat, as indicated in Fig. 2, which shows a set of isoclinics obtained from a disk of about six inches in diameter when subjected to the action of a turning tool with a somewhat acute cutting angle. The lines of principal stress confirm this, and the valves of the minor principal stresses appear to be small in the cases examined so far, and to a first approximation the distribution of principal

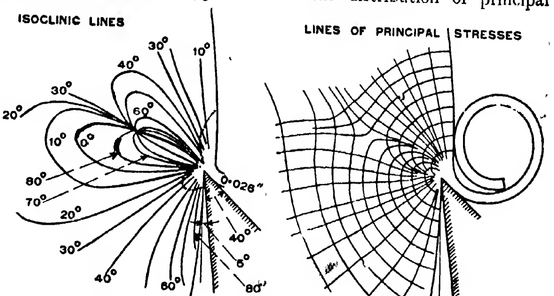

Fig. 2.—Isoclinics and lines of principal stress in a disk under the action of an edge-turning tool. From the Proceedings of the Institution of Mechanical Engineers, by permission of the Council.

stresses $\widehat{RR}$ and $\widehat{\theta\theta}$ may be taken to be of the type

$$\widehat{RR} = (-2P/\pi) \cdot \cos\theta/r$$

where $\widehat{\theta\theta}$ is small, and the angles are measured from the radial black brush dividing the tension from the compression area. The position of this latter brush

[1] "An Account of some Experiments on the Action of Cutting Tools," by Prof. E. G. Coker and [illegible]. Proceedings of the Institution [illegible]

[illegible] cutting angle of the tool, and also upon its [illegible] clearance, but the investigation has not proceeded far enough as yet to define accurately the influence which each element has upon its position.

A somewhat remarkable change from these conditions is produced when the cutting edge is not so perfectly sharp as it is possible to make it. It then becomes apparent that the shaving is no longer cut from the main body, but is broken or torn away by the continual forcing of a wedge between the shaving and the main body of the material, after the latter has once been penetrated. The shaving breaks away at a point A above the cutting edge (Fig. 3), mainly owing to the

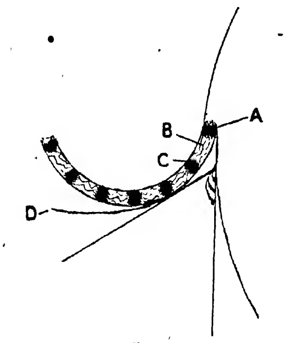

Fig 3.

bending action exerted by the raking face of the tool, and is so much overstressed at this place that all colour effects are obliterated. An intense and permanent black patch is therefore produced separated by a less stressed part B, in which plastic stress colour effects are observable from a similarly much more overstressed part C immediately preceding. These effects are repeated at regular intervals as is indicated in Fig. 3 in a somewhat diagrammatic form, and are accompanied by a rhythmic pulsation of the colour bands in phase with this phenomenon. The tearing away of the shaving in this manner produces a rough uneven surface on the material, which in planed work is therefore not truly flat, and in turned work is not perfectly cylindrical. It is probable that this influences the character and kind of chip produced in brittle materials, as it undoubtedly influences the shaving from an elastic material which is capable of assuming a plastic condition. Moreover, it is sometimes found that when this latter condition occurs the tool is acting in a two-fold capacity, for not only does it break off a shaving, but it may also pare off the irregularities as the point of the tool comes in contact with them, so that occasionally a second and much thinner shaving, D, is produced, and peeled off as indicated in Fig. 3, by a true secondary cutting action. Double shavings are sometimes produced in this manner when steel is turned in a lathe, and it is probable that the fine powder, which can often be observed falling away from a tool working on cast iron, is due to this secondary cutting action.

In tools with multiple cutting edges the same general features of stress [illegible] are observed in [illegible] material. They are sometimes accompanied by additional phenomena, as, for example, with the milling

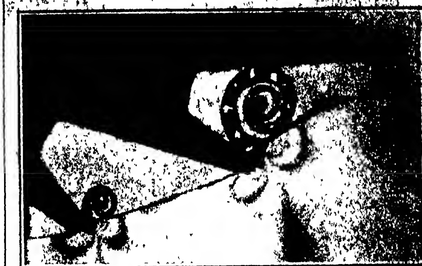

Fig 4.—Steel milling cutter operating on a plate of nitro-cellulose.

cutter, shown in Fig. 4, where the depth of cut is variable owing to the uniform movement of the material up to the cutting edges, which are also turning at a definite and uniform rate. The shaving cut from the trochoidal contour is continuously increasing in thickness therefore, as the cut advances, and in the

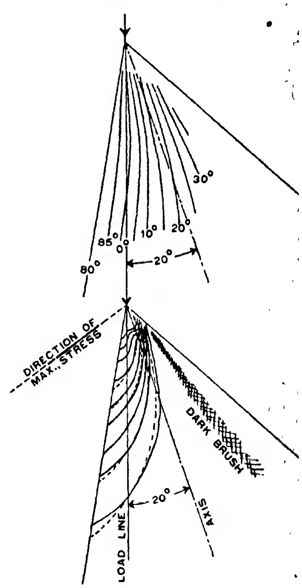

Fig 5.—Isoclinic lines and colour bands observed and calculated for a wedge of angle 60° when a load of 50 pounds is applied at an angle of 20° with the axis Colour bands observed are shown in full lines; equivalent stress lines given by theory are shown dotted. From the Proceedings of the Institution of Mechanical Engineers, by permission of the Council

present instance is being torn off rather than cut, as the characteristic markings for this kind of action occur in a very pronounced manner. If sufficient travel is given to the work, the separate lobed colour bands springing from each cutting edge and denoting approximate radial stress, ultimately [illegible] before

the end of the cut, and the stress distribution becomes much more complicated.

The stress in glass tools when cutting nitro-cellulose has been studied, and it is found that when the material is being removed in a thin shaving by a true cutting action the stress system is of a simple radial type. The colour bands are very nearly arcs of circles passing through the cutting edge as indicated in Fig. 3, and are such as would be produced by the action of a concentrated force applied at this place. They are, in fact, of the same type as those obtained when a non-axial force is applied at the apex of a wedge, giving isoclinic curves and colour bands (Fig. 5), all of which pass through this point up to the yield point of the material. The centres of the circular arcs of these latter bands all lie upon a line passing through the apex and perpendicular to the dark band shown in Fig. 5, which marks the region of no stress. They are, therefore, approximately consistent with Michell's theory of stress in a wedge,[1] and have been shown experimentally, in the paper referred to above, to be in good agreement therewith along the line of action of the applied force. The stress system is found to be almost entirely radial and expressed by

$$\widehat{rr} = -c \cdot \frac{\cos(\alpha - \phi)}{r},$$

along this line—where α is the inclination of the outer face to the line of centres of the colour bands, and ϕ is the inclination of the applied force to the same face. Along each colour band $\widehat{rr}$ is practically constant. The value of the constant c is also expressible in terms of the force P, the angle α and the angle γ of the wedge. The stress system in the case when the material is being torn off by the action of the raking face of the wedge angle of the tool has not, so far, been made out. Experiment shows, however, that it is of a more complicated type, especially when the action is accompanied by the building up of a secondary wedge on the tool from the material torn off in a manner which is familiar to those engaged in machinery operations involving heavy cuts.

The New Building of the National Academy of Sciences, U.S.A.

By Dr. C. D. Walcott.[1]

In 1863 Henry Wilson, United States Senator from Massachusetts, asked a number of men eminent in science to come together to form an organisation by which the scientific strength of the country might be brought to the aid of the government. This meeting was directly the result of an Act of Congress passed March 3, 1863, incorporating the National Academy of Sciences of the United States of America. While Senator Wilson presumably had aid and suggestions from the incorporators, the bill had its inception with, and was drawn by him, and did not incorporate the Academy in any state or territory, or in the District of Columbia. It seems to have been his idea that the Academy should be national in its broadest sense.

The Academy has held its annual meetings in Washington at the Smithsonian Institution and its autumn meetings in other cities. Joseph Henry was president for many years and at the same time secretary of the Institution. The records and library of the Academy have been stored in several hundred boxes at the Institution, awaiting such time as the Academy may have a building of its own where this material can be made available.

The semi-centennial in 1913 gave new life to the activities of the Academy, and the foreign secretary, Dr. George E. Hale, proposed then that the Academy should have a home. He prepared tentative plans and had them put in shape by an architect. These plans provided laboratories and a library for the use of the Academy and resident men of science for research work.

The project was not to be long delayed, for the world war coming in 1914 changed and broadened the thought of the world. What started to be a battle of armed forces turned to competition between the countries at war in creative scientific research, looking to the destruction of masses instead of individuals. This led to the need in the United States of a body that could bring together the most able men in the fields of science for the solution of war problems. Dr. Hale, conceiving the need for such a service long before it was an actual necessity, proposed that the Academy take preliminary steps in the organisation of the scientific resources of the United States, and this was the beginning of the National Research Council which rendered such effective service at the request of the President of the United States during the war.

Appreciation of this service from the Academy was shown in an executive order issued by President Wilson, directing the National Academy of Sciences to continue the Council. Under this order the Research Council was reorganised on a permanent peace basis as an agent of the Academy, and the need of the Academy for a home was accentuated. Dr. Hale's precious plans were discussed at length, but the question of available funds continued. The quarters in the Smithsonian Institution, already too crowded, could not afford room for this new body, and temporary space elsewhere was found in the Munsey Building; then a residence at 16th and L Streets, having twenty-one rooms, was secured. A little later a larger building at 16th and M Streets was occupied, until the present location at 17th and Massachusetts Avenue was leased.

Early in these renewed activities strenuous efforts were made to secure a permanent endowment and money for a building for the Academy, and a suggestion was made to the Carnegie Corporation of an endowment and building for the Academy and Research Council, resulting in an offer of 5,000,000 dollars, provided the Academy would secure a site and present satisfactory plans. The amount needed for the purchase of this site was apportioned, so that the entire country might have a part in the great enterprise. The raising of funds for the purchase of the

[1] Paper read before the National Academy of Sciences on April 24.

ground was accomplished through the efforts of Dr. Hale, Dr. Millikan, and others.

The lot purchased by the Academy is known as Square 88. It contains 189,755 square feet. Originally its highest point was in north-west corner and its lowest point was under water in the river at the south-east. To-day its lowest point is about 24 feet above high water and its highest 41 feet. The borings show that there is a fill of from 5 to 10 feet where the building will stand, from 6 to 28 feet of clay and sand, and from 7 inches to 3 feet of decomposed rock.

The building planned has a frontage of 260 feet and is 140 feet deep. The height above the first floor is 60 feet. The vestibule is 11 by 20 feet; the entrance hall, 36 by 21 feet; the central hall, 64 by 24 feet; the library, 36 by 64 feet; the lecture-room, 34 by 50 feet. The five exhibition halls range in size from 26 by 14 to 34 by 21 feet.

The total number of square feet of floor space, exclusive of elevators, doorways, and hallways, is 39,874. This includes exhibition space amounting to 14,571 square feet, lecture and entertainment space of 7982, and 14,786 square feet for administrative purposes. Every modern convenience and facility will be provided.

Having brought you thus far, let us assume that we are on our way to the annual meeting in 1924. Walking west along B Street, half-way between 21st and 22nd Streets, we find a broad walk on our right, with reflecting pools in the centre leading through a formal effect of trees and shrubs to a building in the middle of the square surmounting a series of terraces. It is the home of the National Academy of Sciences and the National Research Council—a marble structure of fine proportions, standing out in bold relief against the blue sky in the morning sunlight (Fig. 1).

Facing the Lincoln Memorial, the marble building in simple classical style will rise three stories from a broad terrace. On the first floor there will be an auditorium seating some 600 people, a lecture-hall holding 250, a reading-room, library, conference rooms, and exhibition halls. The basement will contain a cafeteria and kitchen. The two upper floors will be devoted to offices.

The building is the gift of the Carnegie Corporation of New York, while the ground was bought at a cost of nearly 200,000 dollars through the donations of about a score of benefactors. Bertram Grosvenor Goodhue of New York is the architect. He is one of the best-known architects in the country, and designed the St. Thomas Church, the West Point Building, the Nebraska State Capitol, and many other buildings. The contract for the construction of the building has been let to Charles T. Wills, Inc., of New York, and it is expected that the building will be ready for occupation in the autumn of 1923. Lee Laurie, the sculptor, has been selected to do the decorations, which will symbolise and depict the progress of science and its benefits to humanity. A series of bronze bas-reliefs will show a procession of the leaders of scientific thought from the earliest Greek philosophers to modern Americans.

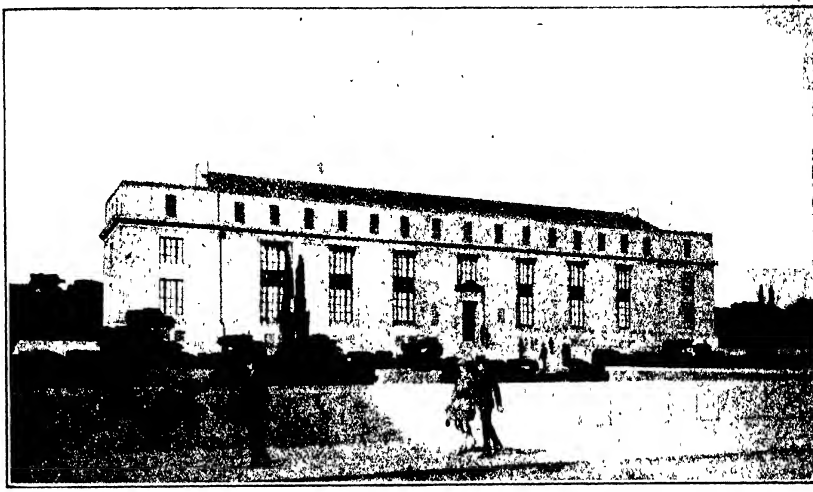

FIG. 1.—New building to be erected in Washington, D.C., for the National Academy of Sciences and the National Research Council.

On passing through the entrance hall the visitor will find himself in a lobby rotunda. Here he will see in actual operation apparatus demonstrating certain fundamental scientific facts that hitherto he has had to take on hearsay. A coelostat telescope, mounted on the dome of the central rotunda, will form a large image of the sun on the white surface of a circular table in the middle of the room. Here visitors will be able to see the sun-spots, changing in number and form from day to day, and moving across the disc as the sun

turns on its axis. A 60-foot pendulum, suspended from the centre of the dome, will be set swinging through a long arc, repeating the celebrated experiment of Foucault. The swinging pendulum will mark an invariable direction in space, and as the earth of the building revolves beneath it, rotation will be plainly shown by the steady change in direction of the pendulum's swing over a divided arc.

Two great phenomena of Nature, the sun and the rotation of the earth, are thus to be exhibited. Other phenomena to be demonstrated in striking form in the central rotunda are magnetic storms, earthquakes, gravitational pull of small masses, the pressure of light, the visible growth of plants, swimming infusorians in a drop of ditch water, living bacteria, and other interesting phenomena.

In the seven exhibition rooms surrounding the central rotunda, the latest results of scientific and industrial research will be illustrated. One room will be set aside for the use of Government bureaus, another for industrial research laboratories, others for the laboratories [illegible] of universities and other institutions. The newest discoveries and advances in the mathematical, physical, and biological sciences and their applications [illegible] shown in this living museum, in which the exhi[illegible] be constantly changing with the progress of s[illegible]. One week there may be displayed the latest form [illegible] radio-telephony; the next perhaps a set of psychological tests or a new find of fossils or a series of synthetic chemical compounds. Such a mutating museum will continue to attract and instruct large numbers of visitors and residents.

We call it the building for the National Academy of Sciences and the National Research Council, but in reality it should be the national home of science in America, and will be looked upon by our fellow-citizens and the world at large as the place where the creative mind will be able to do much to bring about a better existence for the future people of the world, for it is to their enlightenment and advancement that it will be dedicated.

The Internal Combustion Engine.[1]

By Prof. W. E. Dalby, F.R.S.

The Influence of the Internal Combustion Engine.

To engineers the terms horse-power and horse-power hour have strictly technical meanings. They can be illustrated by comparing the weight and efficiency of an aircraft engine and a locomotive engine. An aircraft engine can be built with about 2½ lbs. of metal per horse-power as against approximately 250 lbs. of metal per horse-power in a locomotive engine. An aircraft engine requires about ½ lb. of fuel oil per H.P. hour as against 3 lbs. of coal per H.P. hour used by the locomotive engine, in addition to which the locomotive engine must carry about 3 gallons of water per H.P. hour. All these, of course, are round figures. It is the extreme lightness of the petrol engine in relation to its power which has made it possible to develope aircraft.

An internal combustion engine of the Diesel type is built to use heavy oils, and has provided a prime mover by means of which the submarine was able to develop so considerably during the war. Thus the internal combustion engine helped to sink our food ships, but at the same time helped to save the situation by driving the agricultural tractor. Few, perhaps, realise fully how serious was our position in 1917. Horses were required for the Army and were being taken from the farms; but the agricultural tractor replaced them at the plough and thus made it possible to maintain the necessary food supplies.

Probably the greatest effect of the internal combustion engine on our national life is its influence on road transport. Standing at Hyde Park Corner twenty years ago a motor car would have excited notice; standing there to-day it is almost true to say that the horse-drawn vehicle has practically disappeared. The internal combustion engine is displacing the horse from the streets, and is even causing the railway companies grave concern. The chairman of one of them stated at the last half-yearly meeting that the companies had lost 9 million tons of goods, and 6 million passengers to the motor lorry and the motor car. This is a remarkable achievement for the small 16-20 H.P. internal combustion engine which is fitted in these vehicles. During 1921 about 800,000 licences were issued to vehicles propelled by internal combustion engines and the tax on them amounted to about ten million pounds.

These brief considerations indicate how profound has been and is the influence of the internal combustion engine in shaping our destinies. It has conquered the air, and has given us a prime mover useful in farming and in transport. It is influencing the policy of our railways, and will shortly so transform our outlook and our modes of life that men of to-day will appear to be separated from their boyhood not by a few decades but by a few centuries.

Some Problems of the Internal Combustion Engine.

Considering combustion from the point of view of the Kinetic Theory of gases, but without attempting to explain the nature of the differential attraction between molecules, most of the energy developed in the cylinder of an internal combustion engine arises from the fact that oxygen combines with carbon and hydrogen to develop large quantities of heat. The function of the engine is to convert as much as possible of this heat into mechanical work.

It can be deduced by the laws of gases that the molecules at 22° C. and atmospheric pressure require 729 times the volume they occupied as a liquid. This can be illustrated by "air patterns" representing the distribution of molecules in the air. Actually the molecules are flying about at a high velocity across the vessel the sides of which they are continually bombarding and therefore exerting pressure on them.

Calculation from the kinetic theory of gases shows that at 22° C. the oxygen molecules in the air are flying at a velocity of about [illegible] feet per second, the nitrogen

[1] From a Discourse delivered at the Royal Institution on [illegible]

molecules of about [illegible] ft. per second. This velocity is not the mean but the square root of the mean square of the actual velocities of the particles. The molecules collide and zig-zag about in the enclosing vessel so that it is only by imagination that we are able to conceive them as standing still and forming a pattern something like the pattern on a wall-paper.

When a spark is passed in a mixture of air and a hydrocarbon such as pentane a re-arrangement of the molecules takes place. The 5 atoms of carbon in the pentane molecule produce 5 molecules of carbon dioxide; 12 atoms of hydrogen produce 6 molecules of steam. Before ignition there are 41 molecules including 32 molecules of nitrogen. After the explosion there are 43 molecules, nitrogen taking no part in the change. Oxygen ceases to exist as a separate entity. The result is that every pound of pentane so transformed produces 10,000 lb. calories of heat.

The immediate effect of this production of heat is to increase the velocity of the flying molecules. The actual velocity of the products of combustion in the vessel depends on the mean temperature. Direct measurement of the temperatures of the working charge of a gas engine gives 2570° abs. as a reasonable temperature from which to calculate molecular velocities. At this temperature the carbon dioxide molecules are moving at 3950 ft. per second, the steam molecules at 6166 ft. per second, and the nitrogen molecules at 4950 ft. per second; these numbers being the square roots of the mean squares of the actual velocities.

The next point for consideration is the time taken to effect this change. The time-interval taken by oxygen to combine with carbon and hydrogen lies along a time scale beginning with a detonation and ending with slow burning. In a mixture of air and pentane the oxygen molecules are a long way, on the average, from the carbon and hydrogen of the pentane molecule, and also the freedom of action of the oxygen molecules is clogged by the inert nitrogen present, but the rapidity with which oxygen can combine when the circumstances are favourable is shown by nitro-glycerine.

Chemists have discovered how to produce this nitro-glycerine molecule so that oxygen lies side by side with the carbon and the hydrogen. Its action is unclogged by any other substance, and the molecular distances have been annihilated, or perhaps it would be better to say that they have become atomic distances. Moreover, the molecule contains almost the exact quantity of carbon and hydrogen required to satisfy the oxygen present. As Lord Moulton once put it, it is a case of the lion and the lamb lying down together. A mechanical shock causes an immediate transformation—the lion devours the lamb; and the time-interval for the meal is so short that it is not measurable. This is called a detonation. Chemists have by their researches shown how to combine nitro-glycerine with other substances in order to control the rate of combustion. Engineers are also trying to get control of the rate of combustion of some of the mixtures used in the internal combustion engine. Thus the chemist and the engineer are working in different parts of the same wide field of research.

Experiments initiated by Sir Dugald Clerk are now proceeding at the National Physical Laboratory under the general supervision of the Aeronautical Research Committee for the Air Ministry. Apparatus of the most refined nature has been devised, and the research is being carried out by Mr. Fenning. Various combustible mixtures are made up in a bomb. These are exploded and then the time taken for the chemical combination to take place is recorded. Two results may be mentioned: a mixture of one part by volume of hydrogen, $2\frac{1}{2}$ parts by volume of air, was compressed to 64 lbs. per sq. inch and then exploded. Between the passage of the spark and the beginning of the rise of pressure about four-thousandths of a second elapsed. The combination was complete in about the same interval of time. In another experiment the mixture was diluted with one part of hydrogen and 6 parts of air: this caused delay in the combination, which took six-hundredths of a second to complete. In such diluted mixtures the energy has to be shared by all the molecules which do not take part in the change.

The engineer is faced with two problems: the problem of a too rapid combustion, becoming a detonation, and the problem of a combustion too slow for complete combustion at high speeds.

In practice the turbulence and eddies caused by the rapid admission of a charge through the narrow annulus of an open admission valve results in quickening the rate of combustion, and it is owing to this cause that the gas engine can run at speeds greater than those corresponding to the measured rate of flame propagation for an efficient mixture. Sir Dugald Clerk found a striking difference in the area of indicator diagrams according to whether the mixture was exploded immediately after the admission valve was closed or whether it was exploded after precautions had been taken to damp out the eddies.

Among the problems arising from running internal combustion engines at high speeds is that of torsional oscillations, and synchronous oscillations. There is also the balancing problem. The four-cylinder petrol engine is usually constructed so that it is perfectly balanced for primary forces and couples, but gives the maximum error for unbalanced secondary forces. At certain speeds a model of this type suspended from springs will oscillate twice as fast as the speed of rotation of the engine, while at the same speed and on the same springs a model, balanced to eliminate the secondary forces, will run steadily at all speeds.

Other problems have also to be considered. Accurate records of the pressure-volume relation in the internal combustion engine must be obtained, and the difficulties are increased owing to the high speed at which the cycles take place. The direct measurement of temperature is also a difficult matter, and there are various fuel problems.

Sufficient has been said to show that the future of the internal combustion engine is not settled; it is full of problems requiring continuous and laborious research. The question is what provision has been made for this research. Before the war purely scientific research on the internal combustion engine was focussed largely in the Research Committee of the British Association established at the Dublin meeting in 1908. This Committee was the only one of its kind, and the

work was carried on vigorously until the war under the successive distinguished chairmen, Sir William Preece and Sir Dugald Clerk. The Committee is still in existence. There is also the Research Laboratory at Shoreham under the direction of Mr. H. R. Ricardo, himself a distinguished scientific investigator.

During the war official organisations have been established, and now the Department of Scientific and Industrial Research provides aid in money, apparatus, advice, and encouragement to any individual worker who has ideas and is qualified to carry on a research alone or under direction. This is a great national asset. But above all, so far as the petrol engine is concerned, there is the powerful organisation for Research within the Air Ministry itself, generally under the supervision of Air-Marshal Sir Geoffrey Salmond (known as the Director-General of Supply and Research), but under the immediate direction of Brigadier-General Bagnall-Wild, officially known as the Director of Research. The Air Ministry is advised by the Aeronautical Research Committee under the chairmanship of Sir Richard Glazebrook. This Committee has grown from the old Aeronautical Advisory Committee of the late Lord Rayleigh. Work of the highest scientific value is now in progress at the National Physical Laboratory, at Farnborough, and at other places under the direction of the Ministry.

All I have done here is to hint at some of the work now going on at the National Physical Laboratory; it would take a whole evening merely to epitomise the researches in progress at that institution. Farnborough is now entirely a research establishment in its widest sense, for it is organised both for laboratory and for full-scale work. Work on the internal combustion engine has reached a magnitude and an intensity undreamt of before the war. The war has, in fact, shown that the internal combustion engine instead of being a convenient prime mover to put in our motor cars, to drive our workshops, or even our ships, has become an engine vital to our very existence. The Aeronautical Research Committee realises this, and the Air Ministry also. Let us hope that the nation will realise it too, and that in the need and passion for economy our legislators will not starve research on this vital national prime mover.

The Hull Meeting of the British Association.

Local Arrangements.

ARRANGEMENTS are well in hand in connexion with the meeting of the British Association for the Advancement of Science at Hull, September 6-13. Hull is particularly well provided with suitable rooms for the evening discourses, public lectures, and sectional meetings. Its large City Hall, centrally situated, accommodates three thousand people, and trams for every part of the town start at its doors. In this the inaugural meeting on Wednesday, September 6, will be held at which Sir Charles S. Sherrington (President of the Royal Society) will deliver his presidential address entitled "Some Aspects of Animal Mechanism." On the following day the City Hall will be the scene of the Lord Mayor's reception.

Hull's new magnificent Guildhall provides an excellent reception-room, adjoining which the banqueting chamber makes a very fine lounge and writing-room. On the same floor are suitable rooms for the various officers of the Association, the press bureau, the meteorological demonstration given by the Air Ministry, etc. This last named will be very welcome in the reception room, where it will be seen by everybody, and in an adjoining room the methods of preparing the chart will be available to the members.

Across the road from the reception-room are the British Association refreshment rooms, the Queen's Hall (Section F (Economics) and joint meetings). Section A (Mathematics) meets in the Central Hall, Pryme Street; B (Chemistry) in Waltham Street; C (Geology) and H (Anthropology) in the Museum and Royal Institution; D (Zoology), E (Geography), K (Botany), and M (Agriculture) in the new Art School; I (Physiology) in the Church Institute; J (Psychology) in the Albion Hall; and L (Education) in the Lecture Hall, Jarratt Street. All these buildings are within three minutes' walk from the terminus of the various tram routes in the City Square.

The Local Committee is providing each member with a small badge, which has been artistically designed and will serve as a more convenient means of identification than the somewhat cumbersome members' ticket (this latter, however, is this year to be waistcoat-pocket size and once more includes, as formerly, a map of the meeting-rooms). Each badge bears the number of the member's card, so that a reference to the index at the end of the list of members will enable the identity of any particular member to be ascertained, if desired.

With regard to the accommodation, while it is not expected that there will be any difficulty in providing for as many members as care to visit the city, the hotel accommodation which will be available for visitors is exceedingly limited. This year, therefore, a list of hotels and lodgings will not be prepared, but a special committee is sitting with the object of meeting the requirements of the members. In this connexion rooms are being provided at Bridlington, Hornsea, Withernsea, Beverley, Cottingham, Brough, Ferriby, Hessle, and other places in the immediate vicinity, but the provision of special late trams and of exceptionally favourable weekly contract tickets for this meeting will help considerably. It is desired to impress upon intending visitors to the Hull meeting the necessity of filling in the cards on the back of their preliminary programme, and returning them to the Secretary at the earliest possible moment, in order to prevent unnecessary trouble, which will certainly be caused if members arrive at the meeting without having previously notified their intention of being present. This warning seems particularly necessary, as several members have intimated their intention of being present, but neither state that they have found accommodation nor that they wish accommodation to be found for them. Those who have applied will receive particulars of their rooms shortly.

In a previous article reference was made to the various presidential addresses, with the exception of

[illegible] pleased to announce that Dr. C. S. Myers has accepted the presidency of this section and will deliver an address on "The Influence of the late Dr. W. H. R. Rivers on the Development of Psychology in Great Britain."

An exceptional opportunity at the Hull meeting will be afforded for discussing thoroughly the work of the Corresponding Societies of the Association. This subject has had the serious consideration of the council of the British Association for some time, and at the Hull meeting it is proposed to depart from the practice which has grown up in recent years of looking upon the Conference of Delegates almost in the light of still another section of the Association, and to revert to the former system of discussing the various ways in which the corresponding and other local societies may accomplish useful work. Conditions which obtained since the war are likely to interfere with the work of natural history, geological, archæological, botanical, and allied societies; already the publication of the results of their work has been seriously impeded by the present charges for printing, and in many other ways it seems desirable that this Conference of Delegates shall be more of a conference than of a Section X, to which papers, not quite desired by other sections, shall be sent! Certainly in recent years the connexion between the Conference of Delegates and some of the papers presented at its meetings has been somewhat remote. At Hull, therefore, there will be no set presidential address to the conference.

Advantage will be taken of the fact that the meeting is held in the county in which probably the leading provincial society in the British Isles (that is, the Yorkshire Naturalists' Union) exists, and the way in which this society, by means of its sections, committees, publications, etc., carries out and records its researches will be explained in Hull, as probably upon such lines it will be necessary that other societies should work in the future.

The list of the distinguished members from the near continental countries, from the United States, Canada, and other parts of the world, is constantly growing, and the Hull meeting bids fair to be memorable from the part these gentlemen will take in its proceedings.

Under the editorship of one of the local secretaries a handbook to Hull and the East Riding of Yorkshire is in preparation, and will be [illegible] member. In this booklet an effort will be made [illegible] attention to the various attractions in the Riding, as well as to give descriptions of the city and district under the heads of geology, zoology, botany, archæology, meteorology, commerce, etc.

Elaborate arrangements are being made by a special excursions committee for general and popular excursions to Scarborough, Flamborough, Bridlington, York, Beverley, and other places of scientific interest within easy access of the city, as well as for special excursions of smaller parties of members particularly interested in geology, engineering, chemistry, and other subjects.

In addition to the handbook, a local programme is in preparation, which will contain particulars of the various directions in which the members may be occupied during their stay in Hull. The Constitutional Club, the East Riding Club, and others are electing members of the British Association honorary members of the clubs during the meeting, the Freemasons are giving a reception to their brethren, and special exhibitions of various kinds are being prepared to interest the different sections of the Association. One of these, organised by the Yorkshire Naturalists' Union, will be held in the Board Room of the Education Offices opposite the Museum in Albion Street, and will illustrate the work of the various sections and committees of that society.

The public lectures to citizens so far arranged are as follows:—Dr. A. Smith Woodward on "The Ancestry of Man"; Dr. E. H. Griffiths on "The Conservation and Dissipation of Energy"; Sir Westcott Abell on "The Story of the Ship"; Prof. A. P. Coleman on "Labrador"; and the Rev. A. L. Cortie, S.J., on "The Earth's Magnetism."

Evening discourses will be given by Dr. F. W. Aston on "The Atoms of Matter, their Size, Number, and Construction," and by Prof. Walter Garstang on "Fishing: Old Ways and New."

For the first time, special lectures are being arranged for the children in the upper classes in the secondary and other schools in the city, and these will be given by Prof. H. H. Turner on "The Telescope and what it tells us"; Prof. J. Arthur Thomson on "Creatures of the Sea"; and Mr. F. Debenham on "The Antarctic." Each lecture will be given to two thousand pupils.

T. S.

Current Topics and Events.

An imposing gathering of savants recently assembled in the great hall of the Sorbonne to celebrate the double centenary of the foundation of the Asiatic Society and the discovery by Jean François Champollion of the secret of the Egyptian hieroglyphs, the most important of which is the famous Rosetta Stone in the British Museum. The meeting, presided over by M. Millerand, was addressed by M. Sénart, who pointed out that the Asiatic Society was founded at the period when Champollion, in his famous letter to Dacier, revealed the secret which restored to humanity five thousand years of history. Since then the Society had always been in the van of Orientalism, and Phoenician and Palestinian epi- [illegible]

Sir Arthur Evans, in the *Times* of July 14, announces two dramatic discoveries at Knossos. It had long been observed that the position of the walls at the South-east Palace angle indicated a sudden collapse of the building by what could only have been a great earthquake shock. The discovery of two large skulls of the urus ox, and in front of them remains of portable terracotta altars, showed that "previous to the filling in there had been a solemn expiatory sacrifice to the Powers below—recalling the words of the Iliad, 'in bulls doth the Earth-shaker delight.' There can be little doubt that the great deposits throughout a large part of the Palace area, all illustrating an identical cultural phase [illegible] widespread contemporary ruin [illegible]

about 1600 B.C., were due to the same physical cause. The great earthquake of Knossos, in fact, sets a term to a Minoan period." Even more dramatic than this is the discovery on the South side of what appeared to be the opening of an artificial cave, with three roughly cut steps leading down to what can only be described as a lair adapted for some great beast. "But here perhaps," says Sir Arthur Evans, "it is better for imagination to draw rein." Was this really the abode of the Minotaur?

A BIOLOGICAL expedition is leaving Antwerp for Brazil during this month. It is under the direction of Prof. C. Massart, of the department of botany in the University of Brussels, and there are four other members of the expedition, two of whom are students. For several years before the war the universities of Belgium and Holland organised expeditions to enable students to go into the field under the guidance of their professors, and it is one of these expeditions, to Brazil, which has now been promoted by the University of Brussels. The party will not aim at exploring Brazil; the object is rather to put the young naturalists directly in touch with tropical Nature; they will have the opportunity of collecting botanical and zoological material for study and demonstration and of making ethnological observations. Brazil has been chosen on account of its salubrity and also because, some twenty days' journey from the starting-place, the party will be in the virgin forest. The expedition will remain in Brazil from August until January or February next, and visits will be paid to the States of Rio de Janeiro and Bahia, to the Campos de Minas Geraes, a region in the State of Bahia which is almost deserted, and to some of the peaks of the Serra de Mantiqueira. The necessary financial support for the expedition has been assured by the University of Brussels and the Belgian Ministers of the Colonies and of Sciences and Arts, while the Brazilian Government has promised every assistance for the success of the expedition

THE American Museum of Natural History has recently received from Mr. J. D. Rockefeller, jr., a gift of a million dollars—the largest single donation that has ever come into its exchequer. It is the result of a long and careful inquiry which the donor has caused to be made into the value of the work done by this institution in connexion with the public schools. At the same time, Mr. George F. Baker, a leading New York banker, has given a quarter of a million dollars to the museum. The income from these gifts may be used to extend the direct educational work of the museum, or to assist its research expeditions. The most important of these enterprises being carried on at present is the sending of a party, with specially constructed automobiles, to penetrate the Great Mongolian Desert, a tract which is almost virgin soil for the archæologist and palæontologist.

A NOTE is given in the *Meteorological Magazine* of June from Mr. R. C. Mossman on some recent remarkable temperatures. At Buenos Aires, on the morning of April 26, the shade minimum fell to 27°·9 F. and the grass minimum to 20°·5 F. The previous April shade minimum in the last 60 years was 33°·4 F. On March 10, at Grytviken (South Georgia), the shade maximum rose to 83°·8 F., which is 13° above the previous record.

SIR WILLIAM POPE has been elected president of the International Union of Pure and Applied Chemistry for the ensuing three years. The next meeting of the Union will be held at Cambridge in June 1923.

PROF. A. N. WHITEHEAD has been elected president of the Aristotelian Society for the coming session; he will deliver his inaugural address on November 6.

THE annual meeting of the French Association for the Advancement of Science will be held at Montpellier on July 24-29 under the presidency of Prof. Mangin, director of the Paris Museum of Natural History.

AT the annual general meeting of the Royal Society of New South Wales on May 3, Mr. C. A. Sussmilch was elected president. Mr. Sussmilch is principal of the Newcastle Technical College (N.S.W.), and was for many years lecturer-in-charge of the Department of Geology and Mining, Sydney Technical College. His contributions to science include an account of the geology of New South Wales and a number of papers on geology and physiography.

A MEETING of the Royal Meteorological Society will be held in the Rooms of the Royal Society, Edinburgh, on Monday, July 24, at 3 o'clock, when the following papers will be read: "Observations of Upper Cloud Drift as an aid to Research and to Weather Forecasting," C. K. M. Douglas; "Note on the Effect of a Coast Line on Precipitation," J. S Dines; and "Note on Turbulence," illustrated by smoke and cloud photographs, Dr. A. E. M. Geddes and G. A. Clarke.

IN the Calendar of Industrial Pioneers in NATURE for June 24 it is stated that Singer, who died in 1817, was the inventor of the gold-leaf electrometer. Singer's invention of this instrument may have been independent, but the credit for its first invention belongs to the Rev. Abraham Bennet, who in 1789 included a description of it in his "New Experiments on Electricity." Mr. Shurlock, Principal of the Technical College, Derby, who has kindly pointed this out, says Bennet was a fellow of the Royal Society and for twenty-five years was curate of Wirksworth, Derbyshire, where he died, May 6, 1799, at the age of 49, but that little more is known of his career.

THE death of the eminent anthropologist, Dr. W. H. R. Rivers, has already been recorded in these columns. It will be satisfactory to his many friends, and to others who recognise his great services to science, to know that a full biography, with a complete list of his numerous books and articles, by

Dr. A. C. Haddon, his colleague in the Cambridge Expedition to Torres Straits, and Mr. F. C. Bartlett, appears in the July issue of *Man.* The bibliography of his published work between the years 1888 and 1922 is a remarkable record of the scientific knowledge and powers of work which this scholar possessed, and will increase the regret felt by all his friends and the students of his writings at his sudden and unexpected death in the plenitude of his activity.

AT the first glance one might be tempted to remark that the science master has no concern with the teaching of English, but it is evident from the papers on the subject by Mr. Eggar and by Mr. Breames which have appeared in the *School Science Review* for June 1920 and 1922 respectively, that many science masters have to begin by teaching the boys who come to them to write English. We are told that boys of fourteen who have spent several years on the classical side of a public school are turned over to the science side unable to read English intelligibly or to write it in such a way that their meaning is clear. In such circumstances the science master's task is doubled. He must teach his boys the scientific and technical terms of his subject and also how to express themselves clearly and correctly. Mr. Breames divides the latter process into two stages In describing an object or an experiment he trains his boys to devote one sentence to each feature or to each change. Afterwards he teaches them to combine into one longer statement the sentences dealing with the features or changes which are closely related. He finds that this procedure produces a "respectable style" of writing in about two years.

A BOOKLET from C. F. Elwell, Ltd. (Craven House, Kingsway), shows one of the directions in which wireless telephony is developing, for we have illustrations of receiving sets made up into elaborate pieces of drawing-room furniture in the various period styles of decoration. The apparatus itself within these attractive coverings is in the form of compactly arranged enclosed standard panels, the simplest of which is equipped with a crystal detector. The more useful panels employ valve receivers, and the distance from which they will pick up messages, etc., can be extended by the addition of one or more panels of similar dimensions and appearance equipped with amplifiers. Either head telephones or loud-speaking apparatus can be used, and where the higher degrees of amplification are employed, an indoor loop aerial can replace the outdoor aerial which would otherwise be necessary.

MESSRS. H. K LEWIS AND CO., Ltd., 136 Gower Street, W.C.1, have sent us two catalogues just issued by them, namely, "College Text Books and Works of Reference on Science and Technology" and "Works on Medicine and Allied Subjects." As the lists are carefully classified they should be very useful for reference.

Our Astronomical Column.

IT is stated in the *Times* that the proposal to remove the Paris Observatory to a new site is again under consideration. When the Observatory was erected it was outside the city boundaries, but to-day it is surrounded by busy thoroughfares and streets of tall houses Commenced in 1667 and finished in 1671, a few years before the Greenwich Observatory, the main buildings, as seen to-day, were designed by Claude Perrault, the famous architect of the Louvre. The first director was Dominique Cassini, who had come to France in 1669 at the invitation of Louis XIV, and the directorship remained in the Cassini family for about 120 years. Picard and La Hire were among the first to work in the Observatory, and Grant, in his "History of Physical Astronomy," regrets that Picard's great merits as a practical astronomer were not recognised by his being placed at the head of it. The Observatory contains a fine collection of historical instruments and apparatus used by the distinguished astronomers and physicists who have laboured there, and once a month the public are admitted to see the Observatory and its treasures and to listen to short lectures on the instruments in daily use

CAMBRIDGE UNIVERSITY OBSERVATORY.—It is satisfactory to learn from the annual report of this Observatory, of which Prof. Eddington is director, that its activity, which was sadly crippled during the war, two of the assistants having lost their lives, is now fully re-established The Sheepshanks equatorial is being used for photographic determinations of proper motion of faint stars by comparison of pairs of plates taken 15 or 20 years apart, one of each pair being photographed through the glass to permit of juxtaposition of images, film to film. The regions include those around stars investigated for parallax by Prof Russell and Mr. Hinks from 1903 to 1905, also the region round θ Orionis, and Kapteyn's Selected Area No. 12. Some of the proper motions are being investigated by Miss Payne (Newnham). Miss Douglas (Newnham) is studying the relation between stellar velocity and absolute magnitude.

Mr. W. M H. Greaves has been engaged on various gravitational researches, chiefly connected with the stability of Saturn's Rings, which have been published in the Monthly Notices of the R.A.S.

HARVARD COLLEGE OBSERVATORY'S REPORT.—This is the first annual report issued since Dr. Harlow Shapley succeeded Prof. Pickering, who died in 1919, as director of this observatory. The report shows the wide, sweeping nature of the researches undertaken. Dr. Shapley and Miss Cannon have in hand a discussion of the distribution of stars of different spectral type and magnitudes which occur in the Henry Draper Catalogue The investigations of stellar distances is another line of work in hand which will help in the study of the structure of the stellar system Good progress has been made in the publication of the valuable Henry Draper Catalogue, and volume 97 has just been distributed. By the generosity of private donors the prompt appearance of the remaining volumes is now assured. Numerous discoveries as to stars with peculiar spectra have been made from an examination of the plates of the Henry Draper Memorial, among which the number of spectra having bright lines in the region of the Large Magellanic Cloud has been increased from 48 to 61. The Arequipa station is becoming yearly of more importance, and particularly so now when the distances of southern stars are so much required.

Research Items.

THE ART OF THE MARQUESAS ISLANDERS.—In 1595 the Spanish admiral, Alvaro de Mendana, discovered a group of islands about midway between the Peruvian coast and New Guinea, to which he gave the name of Marquesas, a shortened form of the name of his patron, the Viceroy, Garcia Hurtado de Mendoza, Marques de Canete. In the *Museum Journal*, issued by the University of Pennsylvania, Mr. H. Usher Hall describes a fine collection of the art of the islanders, including finely carved war-clubs, warriors' fillets, amulets made from cylinders of human bones, the war conch-shell, fans carved in whale ivory and wood. The human figures used in the ornamentation of canoes are particularly interesting. The article is illustrated by an exceptionally fine collection of photographs.

THE DEVELOPMENT OF FLINT IMPLEMENTS.—In *L'Anthropologie* (vol. xxxii. Nos. 1-2) M. A. Vayson, under the title of "L'Étude des outillages en pierre," publishes a valuable, well-illustrated article on the development of flint implements. Two principles which he lays down deserve attention: "La similitude des outils n'implique pas la communauté de races ou de civilisation de leurs fabricants; l'identité de forme des outils en pierre ne signifie pas l'identité d'emploi. Ainsi les similitudes vu les différences des outils en pierre que nous pouvons étudier ne permettent pas de conclure nettement sur leur emploi et sur les autres industries dont ils étaient auxiliaires."

A REMARKABLE PARASITE.—An interesting study of the flowers of the parasite *Rafflesia Arnoldii* is published by P. Justesen in Annales du Jardin Botanique de Buitenzorg, xxxii. Pt. 1, 1922. The observations were made on flowers and buds growing on "vines" in the highlands of Sumatra. The paper is illustrated by good photographs showing the form and structure of the large flowers; full measurements are also given of the mature male and female flowers. It is estimated that the complete development of a flower from a prominence just recognisable on a vine root occupies almost a year, and Mr. Justesen gives tables showing the increase in size of the buds during their development. Seven mature flowers were found—four female and three male. One of the female flowers, which is illustrated, measured 64 cm. across, but the largest was 72 cm., while the largest mature male flower measured 75 cm. in diameter. The author gives some details of the ripening of the seeds, which appear to take several months to reach maturity, and he has made some interesting observations as to their dispersion. The fertilisation of the diœcious flowers also presents some unsolved problems. The author suggests that the small seeds may be carried into the earth by termites, and that in so doing they may easily bring them into contact with the roots of the vines. He also suggests, from the finding of Rafflesia in widely separated areas which are nearly always just within the edge of primeval forest, and close to the tracks of pigs and other animals, that wild pigs, pangolins, and mice may be the agents for the wider dispersal of the seeds. A fine model of the flower of *Rafflesia Arnoldii*, which is the largest flower in the world, may be seen in Museum No. 1 at the Royal Botanic Gardens, Kew.

PHYSIOLOGY OF FUNGI.—In the Annals of the Missouri Botanical Garden (vol. viii. No. 5) appear two additions to the excellent series of studies in the physiology of fungi. The first, by G. M. Armstrong, is entitled "Sulphur Nutrition: The Use of Thiosulphate as Influenced by Hydrogen-Ion Concentration." Three fungi, *Aspergillus niger*, *Penicillium glaucum*, and *Botrytis cinerea*, were grown in various solutions containing different compounds of sulphur, and a study was made of the end products of thiosulphate and of its efficiency as a source of sulphur. Reversions of reaction from the more acid condition towards neutrality were observed with both Aspergillus and Penicillium. R. W. Webb, in his study of "Germination of the Spores of Certain Fungi in Relation to Hydrogen-Ion Concentration," finds that the majority of the fungi employed exhibit a distinct maximum of germination between *Ph.* 3·0 and 4·0. It is not until *Ph.* 1·5-2·5 is reached that inhibition of germination is evidenced. A study is made of the effect of different nutrient solutions such as Czapek's solution and solutions of mannite, peptone, and beet decoction, and curves of germination are given for different hydrogen-ion concentrations. In some solutions, *A. niger* and *B. cinerea* on germination produced no change in reaction, but in alkaline cultures of sugar-beet decoction caused a slight shift towards neutrality. The data presented by Webb are of considerable interest and importance and should be taken into consideration in any future study of fungicides or spray mixtures.

GIANTISM AMONG GASTROPODS.—The stories circulated of a gigantic gastropod in the Wealden strata of Sussex have been confirmed by Mr. B. B. Woodward in a paper on "*Dinocochlea ingens*, n. gen. et. sp." (*Geol. Mag.*, 1922, p. 242). A photograph is given of a specimen lying in calcareous sandstone of the Wadhurst Clay series, and it appears that this spiral object is the cast of a gastropod that sometimes attained a length (or altitude) of 2·22 metres (about 7 ft. 3 inches). The affinities of this giant are with the Tiaridæ. The shells are lost by solution, but the spiral casts show that they conformed to molluscan rules of growth. The whorls, some 23 in number, increase only slowly in size from the apex to the mouth, and the whole form is thus fairly cylindrical. Mr. Woodward shows how these objects differ from the concretions that occur in the same beds; but the seemingly abrupt appearance and extinction of Dinocochlea present a fascinating puzzle. The author reminds us that the Carboniferous *Actinoceras giganteum* may have been at least as large. The writer of the present note recalls the vertical cylindrical "concretions," some 10 feet in height, in the Potsdam (Upper Cambrian) sandstone of Blake's Quarry, near Kingston, Ontario, which he inclines to attribute to the burrows of gigantic worms. The notion has hitherto seemed fantastic; but surprises evidently await the palæontologist.

THE "TURTLE-OREODON LAYER" IN S. DAKOTA.—The Oligocene continental strata now under investigation by Princeton University in the Big Badlands of the White River, S. Dakota, afford an interesting parallel with the flood-deposits of Upper Miocene age which entombed the turtles of Old Castile (NATURE, vol. cviii. p. 481). Prof. W. J. Sinclair describes (Proc. Amer. Phil. Soc., Philadelphia, vol. lx. p. 457, 1921) how the remains of enormous numbers of land-turtles occur in all positions in the Oreodon beds, with skulls of mammals, bones gnawed by rodents, and coprolites of carnivores.

[illegible] attributed to temporary floods [illegible] surface on which the animals [illegible] several horizons in the Oligocene beds of Indian Creek Basin calcareous algal crusts have accumulated up to a foot in thickness, probably formed by a species of Cyanophyceæ.

Photosynthesis of Nitrogen Compounds.—In a paper published in the June issue of the Journal of the Chemical Society, Prof. E. C. C. Baly, Prof. I. M. Heilbron, and Mr. D. P. Hudson describe the photosynthesis of nitrogen compounds from carbon dioxide and nitrates. It has previously been reported that decisive evidence of the production of formaldehyde by the action of light on carbon dioxide and water, in the presence of photocatalysts, had been obtained. It is now found that the "activated formaldehyde" so produced can react with potassium nitrate. This reaction takes precedence of the polymerisation of the activated formaldehyde to reducing sugars. When the activated formaldehyde is produced at a rate greater than that at which it can react with the nitrite and with the formhydroxamic acid thus formed, the excess polymerises to reducing sugars. In this case, the two reactions take place simultaneously and independently. Small traces of ammonia are frequently found in the solutions after exposure to light, and activated formaldehyde reacts with ammonia to give methylamine. This confirms Pictet's contention that formaldehyde acts in photosynthesis as a methylating agent. In the synthesis of compounds by the action of activated formaldehyde on formhydroxamic acid, oxygen is set free. The possible modes of formation of indole and quinoline compounds are discussed, and the paper is one which has great interest from the point of view of plant chemistry.

Iron Ore in South Australia.—The Geological Survey of South Australia has recently published in Bulletin No. 9 a very complete account of the iron ore resources of South Australia by R. L. Jack, Deputy Government Geologist. The iron ores of South Australia are of importance, first of all as a flux in smelting, particularly in smelting the silver-lead ores of Broken Hill; ultimately Port Pirie became the centre of this lead-smelting industry, and the bulk of the iron ore required was supplied from the important deposit at Iron Knob, which was acquired by the Broken Hill Proprietary Company. Subsequently this company took advantage of the large supply of good iron ore thus available to erect important iron and steel works at Newcastle, New South Wales. These steel works were started in 1915, and the South Australian production of iron ore went up at once from a little more than 37,000 tons to nearly 265,000 tons, while in 1921 it reached nearly 629,000 tons. Since 1919 the value of the iron ore produced has exceeded that of any other mineral product. A very large number of deposits of iron ore are described in this Bulletin, though it is obvious that the two groups, Iron Knob and Iron Monarch, with estimated reserves of 133 million tons, and Iron Prince and Iron Baron, with estimated reserves of 32 million tons, overshadow all the others in importance. Since South Australia possesses no fuel supplies for metallurgical purposes, the iron ore production is necessarily for export, and on this account the accessibility of a deposit of iron ore in South Australia forms an essential element in determining its economic importance; due regard has been paid to this point in describing the various deposits, stress being laid on those that are well suited for export purposes.

Formation of Thunderstorms.—Mr. E. V. Newnham, of the Meteorological Office, has contributed a discussion, Professional Notes, No. 20, on the formation of thunderstorms over the British Isles in winter. Thunderstorms are rare in winter over eastern England, but they occur more frequently in the west and north. In January during the eight years discussed, 1900–1907, storms occurred on one or two days only, on the east coast of England, but on 19 days at Blacksod Point, 14 at Stornoway, and 11 at Valencia. Forty years ago Dr. Buchan showed that thunderstorms were quite common in winter in the west of Scotland but were very rare in the east. The author has attempted to explain the cause of the winter thunderstorms, following the reasoning generally admitted for the formation of thunderstorms in summer, namely, instability of the air with height caused by a rapid fall of temperature. He attributes the instability in winter to the heat imparted to the lower layers of cold air currents in disturbances which have come from cold northern regions and have subsequently travelled over a considerable area of the warmer ocean. Maps are given showing the trajectories of the January storms he has discussed. It is shown that when a thunderstorm occurred with a south-west or west wind the origin of the air was nearly always in higher latitudes and air which traverses a long stretch of ocean seldom occasions thunderstorms unless it has come from very cold regions, but with these conditions thunderstorms usually occur.

A Direct-reading Spectrometer.—The Government Laboratory exhibit at the Royal Society Conversazione on May 17 included a new type of direct-reading spectrometer made by Messrs. Bellingham and Stanley, Ltd., which embodies several novel features. The optical arrangement is shown in Fig. 1. The light entering through the slit 1 is reflected

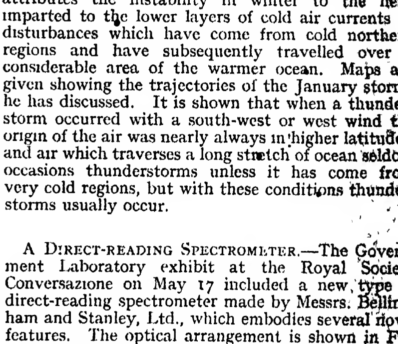

Fig. 1.

by a small right-angle prism on to a concave mirror 3, which directs a parallel beam of light on to the dispersing prism 4. The prism reflects the beam back to the concave glass mirror which brings it to a focus in a plane on the slit 1'. The dispersing prism is mounted on a rotating table which may be turned by the arm 5 operated by the micrometer screw 6. The screw head is divided so that it can be set to pass any particular wave-length of light to slit 1', and thus the instrument can be used as a monochromatic illuminator. For investigations in the ultra-violet the glass prism 4 is replaced by one of quartz, and the mirror is of quartz with mercury tinfoil amalgam backing. When in use as an infra-red spectrometer the dispersing prism is of either quartz or rock-salt. The chief advantages of the design are that the 30° prism is always used in the position of minimum deviation, and that with the concave mirror no chromatic differences of focus are introduced.

Glasgow Meeting of the Society of Chemical Industry.

THE forty-first annual meeting of the Society of Chemical Industry, which was held in Glasgow on July 4-11, was the fourth occasion on which the Society has visited Glasgow, the last visit being in 1910. Last year the Society met in Canada, under the presidency of Sir William Pope, and at this year's meeting it has been honoured by the presence of its Canadian president, Prof. R. F. Ruttan, of McGill University, Montreal, with a party of visitors from Canada and the United States.

The president addressed the Society on "Some Aspects of Scientific and Industrial Research," and, after referring to the influence of the war in directing academic research into industrial channels, spoke of the lesson of co-operation which had thereby been learned, and the prominence now being given to internationalism in science. This was expressed notably in the establishment at Brussels in 1919 of the International Research Council of the Allied and Neutral Nations The Council includes the International Union of Pure and Applied Chemistry, and its ultimate goal is to make a World Parliament of Sciences. This organisation, said the president, should do more than any other for the unification of mankind, because its underlying principle is the universalism of science and the catholicity of truth. The organisation in Great Britain of a State Department of Scientific and Industrial Research has given rise to similar Departments in the Overseas Dominions and the United States. In consequence, a dearth has been revealed of men sufficiently trained and laboratories suitably equipped for research. One of the first problems to be faced by the research organisations is how permanently to associate those pursuing abstract science with those concerned with its application. Universities must be regarded as holding their laboratories and equipment in trust for the community, and they are responsible for inculcating the principles and habits of work which underlie all research. The countries of the Empire expect capacity for research from the scientific departments of their universities, and the universities must therefore have adequate State aid to discharge these responsibilities. Further, Prof. Ruttan advocated the establishment of a State-aided Research Institute in Great Britain, where future scientific and industrial research would be suitably blended. A compromise must be made between scientific ideals and industrial needs; and scientific research should become an accepted responsibility of the State, as certain and permanent as that of national education

A noteworthy feature of the present meeting has been the inauguration of the Messel Memorial Lectures, established by means of a legacy to the Society of Chemical Industry by the late Dr. Rudolph Messel, which was to be applied for ". . the furtherance of scientific research and such other suitable objects as the Council of the Society may determine." The first Messel Medal was presented to Prof. H. E. Armstrong, who delivered a lecture entitled "Rhapsodies culled from the Thionic Epos"

The title of Prof. Armstrong's lecture is explained by the fact that Dr. Messel was the pioneer in the manufacture of sulphuric anhydride by the aid of a platinum catalyst. Besides discussing the mechanism of catalysis and the influence of water in chemical change, the lecturer made an earnest plea for clear thinking in science, for free criticism and exchange of opinion, and for the development of a philosophy of science based on experience. Prof. Armstrong said he was glad that, after the great attention which had been paid to the physical aspects of chemistry, a return was now being made to the consideration of molecular structure, and the inner meaning of chemical phenomena. Advance in the domain of organic chemistry has outstripped that in other branches, because in them there had been little effort to develop a theory of chemical change on the foundation laid by Faraday.

Papers were read by Dr. J. W. M'David on "A Rapid and Accurate Method for the Calibration of Storage Tanks," a method which depends on the time taken to fill the tank to a given level by water forced through an orifice by a constant head; and by Dr. R. A Joyner on "The Viscosity of Cellulose in Cuprammonium Hydroxide," a novelty described being the preparation of the reagent by dissolving finely divided copper in aërated ammonia solution.

The remaining papers of scientific interest were provided by the Engineering Group, which, in its fifth conference under the chairmanship of Mr. J. A Reavell, considered the subject of evaporation and distillation.

In an introduction to an abstract of the papers the relation between evaporation and distillation with reference to modern types of plant was emphasised. Mr. P Parrish presented a paper on the design of ammoniacal liquor stills, in which the origin of the present type of still was traced, details of the composition of ammoniacal liquor were given, and the distinguishing features of the various kinds of still were discussed, together with the physico-chemical principles involved in their use, and the probable lines of future development. Mr. W. A Walmsley dealt with tar distillation In this paper the differences in composition between tar from horizontal and from vertical retorts were considered, and details were given of experiments on the continuous distillation of tar, which yields a greater output than the intermittent process. The treatment of tar fractions was outlined, experiences with modern distilling columns were described, and lines of desirable progress suggested.

The general problem of evaporation was reviewed by Prof. J. W. Hinchley. The influence of various conditions of temperature, atmospheric pressure, and hygroscopic state, radiation, and air-contact upon evaporation was considered. Appropriate evaporation formulæ were developed, their application to details of engineering design was discussed, and their economic importance emphasised. Mr. T. H. Gray read a paper on the historical development of the distillation of glycerine in which interesting drawings of plant were submitted. The importance of economic working was pointed out and the high state of purity of the modern product emphasised. The value of all these papers was much enhanced by the discussions by which they were followed.

A handbook of the meeting had been prepared by the local secretary, Dr. J. A. Cranston, which contained a useful account of the chemical and allied industries of Glasgow and the West of Scotland, prepared by Mr. W. H. Coleman. R. M. C.

The Development of Research in Universities.[1]

By Principal IRVINE, F.R.S., Vice-Chancellor of the University of St. Andrews.

FOR some years it was my privilege to direct the work of a research laboratory where young graduates were trained in research methods and, after a period of collaboration, enabled to strike out independent lines of inquiry for themselves. This endeavour to make research work an organised part of the university's activities was successful, and it occurs to me that the experience thus gained in miniature may be of service in discussing the larger problems associated with the development of research in all subjects, in all universities.

It is not necessary to defend here the idea that research is a vital necessity. My plea is that, although much has been done, our research efficiency as a nation can be vastly improved and the full advantage reaped from present expenditure by changes which in themselves would not be expensive. The functions of a university are threefold: to satisfy the intellectual needs of the people, to lead the communities we serve, and to add to the store of human knowledge. Yet it must be emphasised that every advance made by investigation is something more than a mere addition to knowledge; it means also that some one has gained a rich experience. It is not so much the prize as the discipline of training and the joy of supreme effort which makes any contest worth while, and this applies equally in the world of intellect as in the realm of sport. The universities should not leave original research to the solitary worker, to the unaided enthusiast, but must place facilities for research in the way of every one naturally equipped with the spirit of inquiry.

These ideas are widely spread and are all but universally accepted. The movement in favour of the research development in the universities has suddenly taken shape after many years spent in educating public opinion. Glance for a moment at the phases through which it came into being. In doing so I confine myself meanwhile to research in experimental science, where development has been most rapid and is most easily traced.

I commence with the institution of the 1851 Exhibition Research Scholarships, a wise step which placed at the disposal of a few selected graduates the means necessary for extending formal study by research work.

On this was modelled some nineteen years ago the research scheme of the Carnegie Trust which has done so much to improve the efficiency of the Scottish universities. Whatever views may be held regarding the payment of university fees by the Carnegie Trust there can be only one opinion as to the wisdom and success of this feature of their activities. Notice the points of distinction between the Carnegie Trust Scheme and that of the 1851 Exhibition Commissioners. The latter is confined to scientific subjects alone, and, until recently, scholarship awards were made on one uniform standard. On the other hand, the Carnegie Trust also opens the door to literature, language, history, and economics. The award begins with a scholarship, and from this the best scholars are promoted to fellowships and ultimately to research assistantships, which include teaching duties. There is thus a steady weeding-out process at work, and only the best survive.

There are, of course, other research organisations operating in the universities, but I may pass at one step to the national scheme now administered by the Department of Scientific and Industrial Research. The details of this scheme follow closely the lines adopted by the Carnegie Trust for the universities of Scotland, but differ in the exclusion of non-scientific subjects.

I question very much if the full measure of advantage afforded by these schemes could ever have been attained if the universities had not taken the common action of instituting the Ph.D. degree. Now we are launched on this great new effort. The word "research" is on every tongue. In many subjects of study provision has been made for financing the way to research, and the universities have recognised the movement by the award of the new doctorate. What obstacles and difficulties have already been encountered and what have we still to guard against? These are among the questions I try to answer from an experience admittedly incomplete. Let us take the features common to all universities, irrespective of size or location, and to all subjects of study. The first urgent need I perceive is that our research organisation must recognise the claims of three distinct classes of original workers. These are: First, the young graduate, attracted sometimes by the genuine spirit of research, sometimes by less worthy motives, who in practically all cases is immature and untrained. Then there is the second class, represented by the university lecturer who has passed the apprentice stage and couples with teaching duties the continuation of his researches, frequently through love of the work, sometimes through recognition that worldly wisdom and the hope of a chair make it advisable. In the third place, we have the mature worker and thinker, represented by the professor, the man whose experience is ripe, but whose time, already getting short, is fully occupied with other things.

Each class merges into and feeds the other, and all three classes need help. Prudence points to using the mature material to the best advantage, yet we have never done so, and the research schemes of to-day make the situation infinitely harder than before. The bulk of support is now afforded to the graduate research worker. Scholarships are awarded generously and widely. The conditions attached are moderate and reasonable, and there is now a rush to research. But the young worker has to be trained, supervised, guided, inspired, and this help can come only from the members of my two upper classes—the lecturers and the professors. I wish specially to emphasise this necessity, for I have seen too many good research workers spoiled and discouraged through lack of help, and too many moderate workers developed into investigators of the first rank by careful guidance. Such supervision and training involve the complete absorption of the time and energy of the mature investigator. There can be no formal course of instruction, no common course applicable to all pupils and all topics. Each individual has to be studied. There must be the daily consultations at the laboratory bench, in the library, and round the study fire.

The question of training and supervision must be taken seriously; there is a great danger, particularly in scientific subjects, that this has not been fully appreciated. How great is the temptation in such subjects to use the technical skill of the graduate

[1] From an address on "The Need for the Provision of Enlarged Opportunities for Advanced Study and Research in the British Universities," delivered at the annual Conference of Universities of Great Britain and Ireland, held in London on May 13.

to carry out one's own researches, to regard these young workers as so many extra pairs of hands. Even when the responsibility of becoming a research supervisor is fully recognised, how difficult it is to put oneself in the position of the beginner. The unexpected result is obtained, and the supervisor immediately explains it out of his long experience. What benefit does the student derive? The real supervisor has to curb his impatience and lead his collaborator to sum up the evidence and at long length reach the conclusion for himself. But that takes patience, sympathy, and, above all, time. The supervisor has his reward when gradually the research pupil reveals himself and emerges as an independent worker, but his own research output fades away. There is a novel called "The Devourers," in which a woman of genius finds her artistic development arrested when in time her children claim her every thought. Just as children are in this sense the devourers of their mothers, so are research students the devourers of their professors. When I relinquished my chair I was spending daily three hours at teaching and seven hours with the "devourers."

My first two points may be summarised thus:

(1) Research training must be thorough and must be taken seriously, both by the student and the supervisor.

(2) This training must be in the hands of mature investigators, who should be relieved of routine or administrative work and who need undertake only a limited amount of teaching.

This will cost money, and staffs must be enlarged to supply the main bulk of routine university teaching. There is plenty of room in university organisation for the patient conscientious teacher on whom the gods have been kind enough to bestow only a modest passion for inquiry. Nevertheless, the research supervisor himself must be a teacher and must mingle freely with undergraduates so as to recognise at the earliest possible stage the potential research workers of the future and to guide their studies accordingly.

The needs of the lecturer class of research workers are easily defined. They require more leisure for research than they get at present, and this freedom must not be secured through the agency of overwork and late hours. It should be defined and form part of the terms of appointment. So many hours in the day, so many days in the week, or weeks in the academic year, should be kept free from teaching or administrative work. Here again we encounter the question of finance. Additional staff must be provided, and for this more money is required. In this connexion the research assistantships recently instituted by the Carnegie Trust are a step in the right direction. One other point appeals to me strongly and involves no finance. Every facility should be given the lecturer-investigator to secure collaborators to work under him. I do not mean, of course, that the professor should take the pick of the bunch and leave the residue to his juniors. Every professor should pass a self-denying ordinance on himself in this matter, and, frankly speaking, he will find that it pays.

The professor's needs have already been dealt with, but there is another thing in which we can help him. Again it is a domestic matter. It is, I am convinced, a mistake for a governing body to call for an annual list of publications from their research departments. Nothing could be more injurious to the true atmosphere of research than the feeling of pressure; that papers must be published or the department will be discredited. Thus we have scrappy, incomplete accounts of topics which have been chosen apparently for no other reason than that results will come quickly. One word more regarding the professor: let him have as much financial support for his work as can be spared, but it is well to insist on his keeping these accounts separate from those concerned with university teaching. But these are perhaps petty details compared with the greatest need of the professor-investigator—the necessity to be free at intervals to travel to other centres and refresh himself in the company of kindred workers.

What I have said appears to me to apply generally to all forms of university research and is founded partly on experiences other than my own. I turn now to concrete suggestions. The first and most important is that in each university there should be a Board or Standing Committee entrusted with the supervision of higher study and research. We have Entrance Boards, or Matriculation Boards, governing and regularising the first phase of university study, and it is equally necessary to have such a body assisting in the highest studies. The functions of such a body would be widely varied, and should include the power (1) to recommend additions to the teaching staff in departments actively engaged in research work and to recommend promotion; (2) to allocate money voted from university funds for research purposes, and to see that subjects which are denied benefits from Government or public schemes are properly supported (I speak more particularly on behalf of classical and philosophical subjects, which are in a serious position to-day); and (3) to supervise higher degrees, including approval of the topics given to students.

These need not be elaborated; but here are some specific needs which such a body at once encounters: (1) The provision of research libraries in which reference works can be consulted in the department where the work is carried out; (2) travelling grants to enable workers to visit libraries, to consult authorities, to inspect MSS., or carry out investigations in the field; (3) publication grants, so that where no periodical literature is available in which research results can be published, the work will not remain buried and obscure—the classical and philosophical workers in particular have difficulty in finding a publication medium; and (4) special assistance for subjects not included in National Research Schemes.

As a matter of practical convenience the policy of establishing separate suspense accounts for each of the above has been adopted in the University of St. Andrews, so that heavy expenditure in one year is balanced by accumulations.

An organisation such as I have outlined is, of course, open to some objections. Research cannot be machine-made; it cannot be governed by regulations or committees. The very word "research" is an expression of intellectual freedom. But some organisation is necessary. It is effected on lines similar to those sketched by the Carnegie Trust in Scotland, and in miniature within my own university. The system works well in that the available money is fairly distributed without reference to utilitarian demands. All classes of research workers are stimulated by the feeling that their interests are being looked after and that no subject has preferential treatment. The classical scholar can work in harmony with his scientific brother and without a feeling of envy. Above all, it is a step towards the safeguard that all subjects of inquiry will be prosecuted in the universities, and we may be saved from the degradation of a one-sided intellectual development. The system educates even the mature investigator, and I am sure it is a good thing for the twentieth century chemist to

[illegible] explored, or hopelessly [illegible]. In many branches of study the research [illegible] have got their chance now, and they will have to work hard to justify it. The greatest need is money, so that all subjects may be helped, and our greatest difficulty will be to spend it wisely.

English Place-names.

At a meeting of the Royal Anthropological Institute held on June 27, Prof. A. Mawer, of the University of Liverpool, read a paper on "A Survey of English Place-names." He said that from the earliest times the value of place-names as a possible source of historical knowledge has been recognised. Much early history has frankly been invented from them, and historians have speculated freely as to their meaning. More recently, scholars like Kemble have seen the possibilities latent in place-names; but until Prof. Skeat first put place-name study on its only secure basis, namely, the study of the early forms of the names, most of the work in this direction was only idle speculation. Conducted on scientific lines, place-name study could do much to throw fresh light on the dark places in the history of our country and its civilisation, where we had no documentary evidence or only such as has long been worn threadbare. Place-names and archæology are the only unworked sources of evidence still remaining open to us, and these studies should be conducted in close touch with one another. With the aid of place-names, not only should we have fresh light on long-standing problems, but we should also be furnished with excellent illustrations of many phases of our history and culture.

At present we are only at the beginning of these studies. Much had been done by individual scholars upon single areas, but it has gradually come home to workers in this field that, in addition to such work, we also need co-operative effort, if ever we are to glean the true harvest of knowledge from place-names. The reasons for this are that (1) no safe inferences, either particular or general, can be drawn with reference to the names of any area except in the light of the full evidence for at least the whole of England; (2) the range of interests, historical, linguistic, topographical, and archæological, concerned in the problems of place-names is so wide that they could not be dealt with adequately by any single scholar. These considerations have moved a small body of scholars representative of the various interests named to initiate, under the patronage of the British Academy, a scheme for a survey of English place-names with a view, not only of the interpretation of the individual names, but also of drawing from them all that wealth of historical and cultural lore which is latent in them. During the first six months of work of the survey, a start has been made in several counties; many eminent scholars skilled in the various aspects of the work are giving active help, and close relationships have been established with the two public offices most immediately concerned in the matter, namely, the Ordnance Survey and the Public Record Office.

In opening the discussion, Mr. H. J. E. Peake expressed his gratification that the projected survey of English place-names was not to proceed upon purely linguistic lines, as had been done by earlier workers on this subject, but that archæological [illegible] parishes and [illegible] this country [illegible] the Royal Anthropological Institute had [illegible] will be of assistance in the work of the survey on these lines. In connexion with the survival of [illegible] elements in place-names, to which Prof. Mawer had referred as an instance in which archæological evidence might be brought to bear upon this problem, he indicated the possible connexion between the element "leck" (e.g. in Leckhampton) and a stone, monument or other, and between the element "wick" (e.g. Wickham) and Roman roads. The unknown site of the battle of Wodensburgh, wrongly identified with Wansdyke, to which Prof. Mawer had referred, he himself had identified by archæological evidence within the bounds of Aston Priors, the name possibly surviving in the neighbouring Woodborough. Dr. Singer emphasised the necessity for the study of anthropology of this country, as well as that of the primitive peoples of other parts of the world, to which attention had hitherto been too exclusively directed, and Mr. Nixon gave instances of explanations of Yorkshire place-names which he had obtained by investigations in Norway.

University and Educational Intelligence.

Aberdeen.—The recent graduation ceremony on July 13 was one of the heaviest ever carried through; there were 224 degrees conferred, which included 101 in arts and education, 60 in science and commerce, and 57 in medicine. The special graduation of the previous week was devoted wholly to conferring the degree of LL.D. on ex-President Taft. The Vice-Chancellor, Sir George Adam Smith, presided on both occasions.

Edinburgh.—Mr. J. A. S. Watson has been appointed to the chair of agriculture and rural economy in succession to Prof. Robert Wallace, retired. Prof. Watson was demonstrator in botany under Sir Isaac Bayley Balfour, afterwards continuing his studies in Germany, America, and Canada. He has been lecturer in agriculture in the University for some time.

At the graduation ceremony last week a "record" number of five hundred graduates were capped by the Vice-Chancellor, Sir Alfred Ewing. The B.Sc. degree in mining was conferred for the first time.

Leeds.—Dr. W. MacAdam has been appointed medical tutor and registrar. Dr. MacAdam is a graduate of Glasgow University. He was awarded the Brunton Memorial prize as the most distinguished graduate in medicine of the year, and, after completing his University course, held the McCunn scholarship and the Carnegie scholarship in physiological chemistry. For two years he was senior assistant tuberculosis officer in Sheffield, and was at the same time a demonstrator in Sheffield University. He has been lecturer in pathology at the University and has held a number of medical posts. Mr. H. W. Symons and Mr. P. J. Moir have been appointed clinical assistants in surgery; both have been closely associated with hospital work for some years. These appointments, to new full-time posts, mark an important step in the development of the clinical teaching of medicine and surgery.

Manchester.—The Council has appointed Prof. J. S. Dunn to the Procter chair of pathology and pathological anatomy in succession to Prof. [illegible] R. [illegible] Prof. Dunn at present holds the chair of [illegible]

pathology at the University of Birmingham. Mr. W. W. C. Topley has been appointed to the chair of bacteriology and to the directorship of the Public Health Laboratory. Mr. Topley is at present director of the Institute of Pathology and lecturer in bacteriology and pathology at Charing Cross Hospital, London.

It is announced that Mr. R. M. Wilson, at present principal of the East Anglian Institute of Agriculture, Chelmsford, has been appointed principal of the South-Eastern Agricultural College, Wye.

The Empire Cotton Growing Corporation will shortly appoint an assistant for cotton research in St. Vincent, West Indies, whose duties will consist of genetics research on the cotton plant. The salary offered is 600*l*.-700*l*., with free bachelor quarters. Further particulars are obtainable from the Secretary of the Corporation, Millbank House, Millbank, S.W.1. The latest date for the receipt of applications for the post is Thursday, August 10.

A number of evening advanced courses in technology are being organised as usual for the coming session by the University of Leeds. Students who are under the age of twenty-two are required to produce evidence of adequate preparation for the courses or to pass an entrance examination before they will be admitted. Courses are held in civil, mechanical, electrical, and gas engineering, coal mining, textile industries, colour chemistry and dyeing, leather industries, fuel, metallurgy and geology. Many of the courses are specially suitable for those desirous of undertaking research work.

Two Frecheville Research fellowships are being offered by the Imperial College of Science and Technology, South Kensington, to aid in carrying out any investigation or research connected with mining, mining geology, metallurgy, or the technology of oil, which, in the opinion of the Selection Committee, is of sufficient use or promise. Each fellowship will be of the annual value of 300*l*., tenable for one year, with a possible renewal for a second year, and the holder will be expected to devote his whole time to the work of the fellowship. Further particulars may be obtained from the secretary of the college, and all applications must be lodged with him before September 1, information being furnished at the same time as to the qualifications of the applicants and the nature of the proposed investigations.

The president and council of the Royal Society propose to create a Foulerton Research Professorship and a Foulerton Research Studentship, the duties respectively of each being "to conduct such original researches in medicine or the contributory sciences . . . as shall be calculated to promote the discovery of the causes of disease and the relief of human suffering," and "to conduct researches in medicine or the sciences under the supervision and control of the managing committee." The annual value of the professorship will be 1400*l*. and that of the studentship 700*l*. Members of either sex are eligible for appointment. Applications must reach the Royal Society, Burlington House, Piccadilly, W.1, by, at latest, October 31.

The West Indian Agricultural College, which has materialised as the result of the report of a committee on the question, referred to in Nature of April 1, 1920, p. 153, will be opened in October next, in temporary accommodation which has been acquired at St. Augustine, Trinidad. [illegible] representing the University of Cambridge, [illegible] and Sir David Prain, representing [illegible] Darnley, the Secretary of State for the Colonies, deputy chairman of the governing body, on which will be also representatives of the University of Glasgow, the Royal Botanic Gardens, Kew, and the Imperial College of Science and Technology. The College will aim at providing a three years' diploma course in tropical agriculture for those desirous of following the business of tropical planting, and a shorter course for those unable to take the full course; there will also be facilities for research. Sir Francis Watts will combine the duties of Principal of the College and Commissioner of the Imperial Department of Agriculture, which has been amalgamated with the College. The College has offices at 15 Seething Lane, London, E.C.3, and further details of the courses can be obtained from the secretary, Mr. A. Aspinall, at that address.

Prof. Alexander Mair, writing in the Bulletin of the Association of University Teachers, says—"Research . . . is the fashionable cant word of our generation." He deplores "the fact that so many men and women . . . are induced to spend one or two important years in doing pedestrian work that could equally well be performed by an intelligent mechanic or clerk" owing to the fallacy that free creative activity can be commanded by a mere fiat. A similar warning is embodied in an article on Medical Research in the report for 1920–21 of the president of the Carnegie Foundation for the advancement of teaching. "Every college and university," he says, "covets the reputation of being a centre of research. . . . The result of this striving is that the thing which ought to be the greatest inspiration toward good teaching has become only too often an excuse to escape the primary duty of teaching." In Prof. Mair's article reference is made to "an inquest into the whole question" (of research by members of university staffs) which, it seems, the Association of University Teachers is undertaking.

The retirement is announced, on the ground of failing health, of Mr. Sidney H. Wells from the post of Director-General of the Department of Technical Education of the Egyptian Government. Mr. Wells was appointed to that position in 1907 upon the creation of the department by Lord Cromer, and during his fifteen years' service has organised technical, agricultural, commercial, and industrial education in all branches. Generally speaking, schools of three grades in each of the sections named, elementary, intermediate, and higher, have been created, and there are now nearly fifty different institutions at work in the country extending from Alexandria to Assouan. With the creation of the Ministry of Agriculture, the direction of the agricultural schools was transferred to that Ministry, and it is intended to incorporate the Higher Colleges of Engineering and Architecture, and of Commerce, with the proposed new Government University of Cairo. For his work during the war as Director of Civilian Employment for the Egyptian Expeditionary Force, Mr. Wells was mentioned in Lord Allenby's dispatches and in 1919 was awarded the C.B.E. He also holds the insignia of Grand Officer of the Mejidieh Order, and of the Order of the Nile conferred by the Khedive Abbas and Sultan Hussein for his services to Egypt. Mr. Wells will be remembered as the first Principal of the Battersea Polytechnic, which position he held from the building of the institute until his departure for Egypt in 1907.

[illegible] The story of the sewing machine is one of the romances of modern industry. To such as Thomas in England, Thimmonier in France, and Howe and Wilson in America are due the main features of the machine, but it was the Boston mechanic Singer who made it available for even the poorer people. Singer patented his machine in 1851; the Singer Manufacturing Company dates from 1863, while the annual output of machines rose from 21,000 in 1863 to 800,000 in 1896. To-day the Company produces more than 2,000,000 machines a year.

July 23, 1876. Henry Deacon died.—A successful industrial chemist, Deacon was born on July 30, 1822, in London, where at an early age he came under the influence of Faraday. He was trained as an engineer by James Nasmyth—for whom it is said he made the first model of the steam hammer—and afterwards became manager of glass works and chemical works. In 1855, with Gaskell, he founded the firm of Gaskell, Deacon and Co., manufacturing carbonate of soda, attacking the ammonia soda process, and taking out many valuable patents. With Gossage and Muspratt he was one of the founders of the prosperity of Widnes

July 24, 1899. Sir Arthur Thomas Cotton died.—Like his contemporary, Sir Proby Thomas Cautley, Cotton was trained as a soldier but became a great irrigation engineer. He not only carried out many of the earliest and most important irrigation schemes in India, but he founded a school of hydraulic engineers, which is still engaged in the development of the resources of the Indian rivers

July 25, 1843. Charles Macintosh died.—Born in Glasgow, December 29, 1766, Macintosh was enabled to attend Black's lectures at Edinburgh, and in 1786 he set up as a manufacturing chemist. In 1797 he started the first alum works in Scotland, and for many years was connected with Charles Tennant of the St Rollox Works, Glasgow. His name is popularly known at the present time, however, for his invention in 1823 of a method of making cloth waterproof by cementing two thicknesses together with a solution of rubber in naphtha, an invention which, together with the discoveries of Goodyear and Hancock, laid the foundation of the rubber industry.

July 28, 1886. Sir John Anderson died.—An eminent mechanical engineer, Anderson was trained in Scotland, and after working with Fairbairn, John Penn, and David Napier was appointed in 1842 to Woolwich Arsenal, where he effected a complete revolution in the method of manufacturing guns and small arms, and ultimately became superintendent of machinery. He wrote a treatise on the strength of materials, lectured at the Royal Military Academy, and was officially connected with some of the great exhibitions.

July 29, 1708. Swalm Renkin died.—Known as the constructor of the famous "Machine de Marli," Renkin was born at Liége in 1644, and at an early age acquired a high reputation for his skill as a carpenter and millwright. Employed by Louis XIV. on the plans for conveying the water of the Seine to the fountains and works at Versailles, Renkin began the great machine in 1675 and completed it in 1682. The machine is said to have cost 8,000,000*l*. It consisted of 14 water-wheels driving no fewer than 253 pumps, some of which worked at a distance of three-quarters of a mile by chains and rods. The water was raised in three stages to a height of 533 feet, whence it flowed to Versailles by an aqueduct. This "gigantic specimen of a race of mechanical megalosaurians" was dismantled in 1817, and the water pumped by one of Watt's steam engines. E. C. S.

Societies and Academies.

LONDON.

Faraday Society, June 26.—**A. W. Porter** and **J. J. Hodges**: The law of the distribution of particles in colloidal suspensions with special reference to Perrin's investigations. Perrin found that the particles of a suspensoid distribute themselves according to the same law as the molecules in an atmosphere of gas; but his experiments extended over only a very small range of depth. Observations have been extended over a much greater range and wide divergence from the gas law is found; *e.g.* for the concentrations employed the concentration becomes sensibly uniform in a depth of one millimetre. Curves are fitted to the observations and the question is examined theoretically as well as experimentally.—**W. R. Cooper**: The electrochemical effects produced by superimposing alternating currents upon direct currents. Previous authors have shown that when an alternating current is superimposed on a direct current increased corrosion is obtainable and the overvoltage may also be reduced. It is now found that low frequency currents do not affect the amount of deposition or corrosion in the case of copper plates in copper sulphate The view expressed by Goodwin and Knobel that alternating currents affect hydrogen overvoltage only when the conditions are such as to give a reversal of current in each period appears to be incorrect. The effect increases as the strength of the alternating current is increased, but the percentage effect becomes less, and takes an appreciable time to pass off when the current is discontinued. With platinum wire electrodes in dilute sulphuric acid, low frequency current gives the greatest effect when the applied voltage for the direct current is below the decomposition voltage, but this is not the case with high frequency currents. The absorption of hydrogen is very marked and there are other differences between the electrodes. If a fine platinum wire and a comparatively large platinum surface are used as electrodes, a high frequency current causes an electric discharge to take place under certain conditions. The resulting bubble forms in the body of the electrolyte, at a distance from the electrode, and the discharge is luminous in the dark.—**T. M Lowry** and **E. E. Walker**: Expansion and shrinkage during caking of potassium carbonate. Photographic evidence is given of the expansion and subsequent shrinkage of an old package of potassium carbonate, after emptying out into a jar. Attempts to produce artificially such an expansion in various modifications of potassium carbonate have led to negative results. A possible explanation of the expansion assumes the presence in the material of a sesquihydrate, which expands on conversion into the dihydrate. Data are given in reference to the methods of preparation of this sesquicarbonate.—**T. M. Lowry** and **L. P. McHatton**: The powdering of minerals by decrepitation. The decrepitation of barytes may be attributed, as in the case of water-soluble salts such as lead nitrate, to the presence of included water; clear fragments have been obtained which are completely resistant to decrepitation by heat and a semi-quantitative relationship has been found between the water-content of barytes and the fineness of the powder produced by decrepitation. The decrepitation of celestine, crocoite, and common salt has also been investigated.—**A. M. Williams**: Two properties of powders. It is suggested that specific surface should be referred to unit mass and not to unit volume, owing to the relative difficulty of measuring

the latter in [illegible] division. The [illegible] its relation to [illegible] powder as obtained by the immersion method, and a new criterion to distinguish between a physical and a chemical change in certain cases is given.—J. L. Haughton and G. Winifred Ford: A note on the systems in which metals crystallise. In the majority of cases the system in which a metal crystallises depends on its position in the periodic table. Alloys which form a homogeneous series of solid solutions right across the diagram generally crystallise in the same system. There is apparently no relationship between the changes which occur in the physical properties of metals at the melting-point, and their crystalline habit. A possible exception is the electrical resistivity of the metals in the odd series of group 5.—A. J. Kieran: The electrical conductivity of hydrochloric acid and potassium chloride in presence of sucrose. The equivalent conductivities of hydrochloric acid, through a wide range of dilution, were determined in the presence of varying quantities of sucrose, the concentration of the latter being maintained constant in each series of measurements. While the behaviour of potassium chloride in presence of sucrose is normal, in that the equivalent conductivity increases regularly with increasing dilution of the salt to an asymptotic limit, that of hydrochloric acid is abnormal, the equivalent conductivity passing through a maximum and falling thereafter with increasing dilution. This is connected with the relatively minute traces of electrolytic impurity present even in the purest samples of sucrose obtainable. The nature of the abnormality is of interest in view of the close association of minimal amounts of electrolytes with other organic substances of high molecular weight.

PARIS.

Academy of Sciences, June 19.—M. Emile Bertin in the chair.—Marcel **Brillouin**: The isotropic field. Heterogeneous fluid sphere.—Maurice **Leblanc**: A new freezing machine with air as the working fluid. A detailed description, with diagrams, of a machine based on the principles given in an earlier communication (June 12). The results obtained by this machine will be published later.—Charles **Depéret**: An attempt at the general chronological co-ordination of the quaternary period.—A. **Rateau**: The pressure and specific gravity of air in a normal atmosphere.—M. **Riquier**: The elimination of arbitrary constants.—G. **Friedel** and L. **Royer**: The liquids of Grandjean with equidistant planes.—M Charles Gravier was elected a member of the section of anatomy and zoology in the place of the late M. Ranvier.—M. **Gosse**: Partial differential equations of the second order integrable by the method of Darboux.—Bertrand **Gambier**: Applicable surfaces with equality of the principal radii of curvature.—L. **Dunoyer** and P. **Toulon**: The polarity of the electric arc.—B. **Szilard**: A new electrometer with rigid pointer designed for the measurement of radiations. A description and diagram of the instrument are given: the advantages claimed are transportability, easy adjustment to the zero of the scale, and sensibility. A visible displacement is obtained with 0·01 gram black uranium oxide free from uranium-X.—F. **Guéry**: A curious property of a special mounting of electrical machines excited in series.—Edouard **Belin**: The transmission of handwriting and drawings by wireless telegraphy. An account of additional experiments by the method described in an earlier communication. A reproduction is given of a radio-[illegible]

[illegible] precipitate [illegible] with it a considerable proportion of [illegible]. The oxide of uranium-X is less basic than uranium oxide.—Max **Geloso**: The absorption of iron by precipitates of manganese dioxide.—Ch. **Dufraisse** and P. **Gérald**: The action of alcohols on α-bromo-benzalacetophenone.—Henri **Longchambon**: Study of the tritoluminescence spectrum of saccharose. Previous work on this subject has led to the conclusion that the light given out when crystals of sugar are crushed is continuous. It has now been proved that the spectrum is discontinuous, and the bands observed correspond with the second positive band spectrum of nitrogen. The effect is probably due to a silent electrical discharge between two solid particles of sugar suddenly separated and charged electrically. This view is confirmed by the fact that when sugar is broken in a vessel containing air under reduced pressure (40 mm. to 1 mm. of mercury) the luminosity is much more intense.—St. **Jonesco**: The distribution of the anthocyanidines in the coloured organs of plants.—E. **Wollman** and M. **Vagliano**: The influence of avitaminosis on lactation. A rat fed with food deprived of vitamins is incapable of supplying its young with the vitamins necessary for growth. Young rats, from the earliest days of their existence, can utilise vitamins of foreign origin (from yeast and butter).—G. **Mouriquand** and P. **Michel**. Auto-immunisation against deficiency diet.—L. **Panisset** and J. **Verge**: The "donneurs de sang" (horses providing blood for transfusion) in veterinary medicine. The transfusion of blood from one individual to another of the same species is known in the case of man, to be attended with certain risks (agglutination, hæmolysis). Laboratory experiments *in vitro* and also clinical practice show that these risks are very small with horses or with cattle.—Jean **Delphy**: *Gregarina Sænuridis* and its host.—W. R. **Thompson**: The study of some simple cases of cyclic parasitism in entomophagous insects.—C. **Levaditi** and S. **Nicolau**: Vaccine and neoplasms.

The Cause of Rickets.

SO much has been heard in recent times of rickets as a disease due to a deficiency of the fat-soluble vitamin A which promotes growth, that it is a good corrective to examine again the position of those observers who do not agree that the disease is essentially an "avitaminosis," as the French would say. An interesting survey of the work of the Glasgow school from this point of view is given by Dr. Leonard Findlay in the *Lancet* (April 29, 1922, vol. i. p. 825). He there reviews the variety of investigations which have been carried on for some 15 years by himself and his collaborators—clinical, experimental, and sociological—and comes finally to the conclusion that "confinement and defective hygiene are the most potent causes in the production of rickets." While opinions will differ as to whether this summary may not be too comprehensive, no one can fairly say that the facts which he adduces are compatible with a positive conclusion that rickets is due to a deficiency of fat-soluble A. It is fortunately no longer necessary to try to decide which of these two views is correct for, as so often happens, it is now pretty clear that both are right, and, which deserves less notice, that both are wrong. The two propositions are indeed not contradictory but complementary.

In the same journal (July 1, 1922, vol. ii. p. 7) appears a preliminary account by Dr. Chick and her colleagues of their observations on children in Vienna which goes far to reconcile and harmonise the two points of view. By very careful experiments they show clearly that under certain conditions rickets can be controlled by cod-liver oil, and it is legitimate to assume for the present that the active factor is fat-soluble vitamin A. They also show (1) that the well-known seasonal prevalence of rickets in the winter and early spring finds a rational explanation in the preventive and curative action of sunlight, which can be duplicated by rays from a mercury vapour quartz lamp, and (2) that under equal conditions of diet and environment the disease develops much more readily in children under six months of age than in those a little older, presumably in correlation with the more rapid rate of growth, as Mellanby found in his experiments on dogs. The occurrence of rickets is evidently conditioned by a number of circumstances, of which one or another may in any given case be the "cause" in the pragmatical sense that attention to it may give satisfactory prophylaxis or cure.

From the vast amount of clinical and experimental work on the subject which has appeared in the last two or three years it seems possible to disentangle a certain number of definite data. If conditions are otherwise

favourable, rickets may be [illegible] diet, the deficiency being in the sense of (i.) too little fat-soluble A, (ii.) too little calcium and phosphate, (iii.) too little meat and too much bread; (b) by bodily confinement and lack of exercise or by rapid growth; or (c) by the absence of sunlight. Conversely, rickets may be ameliorated or cured by (a) giving plenty of fat-soluble vitamin in cod-liver oil or butter, avoiding too much cereal food, and (which is of experimental rather than practical importance) having a reasonable amount of calcium and phosphorus in the diet; (b) by encouraging metabolism by massage and electricity, or, which comes to the same thing, by being careful that the total intake of energy in the food is no more than is necessary; or (c) by exposing the skin to open sunlight or to sources still richer in ultra-violet light, such as mercury vapour lamps or metallic arcs.

Dr. Findlay rightly objects to any superficial conclusion from this array of circumstances that rickets has many causes. A disease of so definite and isolated a species must be held *prima facie* to have but one cause. What that *vera causa* is we do not know, but evidently if the various contingencies that have been enumerated can be reduced to some common factor, some progress will have been made in its discovery. In the analogous case of beri-beri it is known that the quantity of vitamin B which is required to avert the onset of polyneuritis in experimental pigeons is proportional to the quantity of carbohydrate in the diet. It seems likely that the quantity of vitamin A necessary to prevent or cure rickets varies similarly with the intake of other food. A full diet and rapid growth encourage its onset: a meagre stunting allowance is to some extent a preventive. The quality of the food is evidently also of importance: it must contain an adequate and balanced supply of the materials necessary for bone formation, and, though this is still obscure, the right kinds of proteid (animal rather than vegetable) and no large excess of carbohydrate. It also makes a difference whether the food absorbed into the economy is used for energy production or for storage and growth. Exercise, even that brought about by the irritation of the itch, according to Dr. John Mayo (1674), is antagonistic to rickets, and if the child cannot take it in the ordinary way massage and electrical stimulation may supply it.

It appears, therefore, that the amount of vitamin B which is necessary varies with the proportion or quantity of food which is not used for energy production. If all other conditions are as favourable as possible, the vitamin may with some children be reduced without ill results to amounts which appear to be very small by the available method of testing on growing rats: from which comes the conclusion that the vitamin [illegible] on the other hand, any or some of the other conditions are unfavourable, the quantity of vitamin [illegible] abundance, *e.g.*, of butter or cod-liver oil—may make all the difference between a healthy and a sick child: hence the conclusion that vitamin B is the most important factor. Even in respect of the necessary components of bone, the vitamin is quantitatively important. Rickets may be induced in rats by a deficiency of vitamin A and of calcium, but not by a deficiency of either substance alone. The vitamin in this case enables the growing tissues to make use of a concentration of calcium which otherwise they would be unable to utilise for bone formation. Such observations may in time elucidate the relative weight of the various factors of which at present it is known only that they are quantitatively related to one another.

To bring the influence of ultra-violet rays on the skin into this conception of the causation, or rather the contingency, of rickets, it is not difficult to believe that it acts by increasing general metabolism, in other words by giving exercise. It is known that inflammatory and sub-inflammatory processes in the skin may lead to the generation of substances which are absorbed into the circulation and affect the whole body, *e.g.* by increasing the susceptibility of the whole skin to the action of some local irritant. By some similar process, metabolism might easily be affected. It is also possible that vitamin A is developed in the skin under this form of stimulation, though the nocturnal and crepuscular habits of our pigmented hairy predecessors make it difficult to explain the phylogenetic history of the mechanism. Whatever the solution, the observation that rickets may be cured by short exposures to the mercury vapour lamp in hospital wards provides a welcome experimental confirmation and partial analysis of the sociological finding that the conditions of life in the dreadful tenement flats of Glasgow are *per se* conducive to the disease.

The question therefore "What is the cause of rickets?" is at present as insoluble as the problem "Is the tubercle bacillus the cause of tuberculosis?" The answer in both cases is that it depends on circumstances. In the latter case we have, however, reached the stage when we can say that tuberculosis is impossible without the tubercle bacillus: the bacillus has been identified as the ultimate limiting factor. That absence or deficiency of vitamin A occupies the same position in respect of rickets has yet to be shown. It seems likely that it does, but the demonstration has not been made that cod-liver oil will avert rickets when all other germane circumstances have been arranged [illegible]

[illegible] *The Reconnaissance*, 1921. By Lieut.-Col. C. K. Howard Bury and other Members of the Mount Everest Expedition. Pp. xi + 356 + 33 plates + 3 maps. (London: E. Arnold and Co., 1922.) 25s. net.

THIS is a very attractive book with its wealth of beautiful illustrations, and the interest is great, whether told by Col. Howard Bury himself, or in the introduction by Col. Sir Francis Younghusband, by the surveyors—Major Morshead, Major Wheeler, and Dr. Heron—by other members, Dr. Wollaston and Mr. L. Mallory. The latter's knowledge of the Alps makes his portion a valuable contribution. The description of the monasteries, the beautiful type of their architecture shown in photographs, will be new to many. Of the Lamas themselves and their orderly system of government we find the same from one end of Tibet to the other. This will interest and prove instructive; readers will find they are not ignorant savages, but a people highly advanced in arts and education, and in many respects far more practical, united, and sensible than we are. Of course it is not new; much can be seen in Ladak and in the fine monastery of Himis near Leh, but what is new is the degree to which the tameness of wild animals and birds has been brought by the Buddhists living under the shadow of Mount Everest, markedly by those leading a hermit life in the Rongbuk Valley.

There are some striking lines in chapter 12, p. 183, where Mr. Mallory describes his feelings on the first good view of Everest, feelings shared in by Mr. G. H. Bullock on their sighting it at 57 miles distance from Shiling, west of Tinki, their first impressions of what was before them. I was struck by, and like, what Col. Howard Bury says on "Back to Civilisation," p. 176. The right type of traveller is shown here:

"There was sorrow in our hearts, however, at parting with the friendly and hospitable folk whom we had encountered, and at leaving behind us the familiar landscapes with the transparent pale blue atmosphere that is so hard to describe and the distant views of range upon range of snowy mountains often reflected in the calm waters of some blue coloured lake. The attractions of Tibet may yet be strong enough to draw us back again once more."

It is very disappointing to read in the *Geographical Journal* for May, p. 380, that "No Survey of India party is to go this year, and that Dr. Heron of the Geological Survey has not been allowed by the political authorities to continue his geological work." This may possibly be got over, but I fear that what I said in my article in this Journal last year on our successful en[illegible] Geographical Society, "Our [illegible] must be completely, may not be realised."

These are investigations of true interest and value in connexion with the history of the Himalayan Range, the combining of accurate topography with knowledge of the rocks, so that a formation, say like that of the Ladak Range, can be traced mile after mile for a considerable distance, defining the age of the rocks both on the north and south of it.

The climbing of Mount Everest, on the other hand, is of secondary importance compared to what will be lost by political exigency, partly because "there was some little difficulty last year about the disturbance of the dragons that live under the sacred mountains" (quoting from the *Geographical Journal*, May 1922, p. 380). As a member of the Bhutan Mission in 1863–64, I remember what unreasonable, unexpected difficulties they will throw on the traveller going to any particular peak, or in any particular direction.

The past year's work, so well recorded in this book, has given us an insight into the geology and topography of the great peak. We know of the many valleys descending from it, towards the northern Tibetan side, and the type of the glaciers. It is lamentable to be told that Dr. Heron will not be able to complete his survey of the metamorphosed sedimentaries and associated granites, even on the limited slopes above the Chang La, which this year's expedition will reach, for there would be much detail for Dr. Heron to observe, and whether the "Daling Series" extends thus far.

I draw a line between climbing and mountaineering. There is a charm in the first, similar to that felt in the rigging of a ship by every sailor when he ascends to the main truck or lays out on a yard in a stiff breeze—there is a spice of danger in it. The second—and Mallory comes in here—demands a period of apprenticeship to gain that eye for ground which tells the surveyor where he can go, where he cannot, and the time it will take him to get over any particular section of country. Mountaineering is the highest form of athletic exercise that can be conceived; mind and knowledge enter into it.

I have long doubted the possibility of reaching the summit of Mount Everest by several thousand feet. What is the possible height attainable only those who have been on its side can guess. It is now being solved. I am guided by past experience at much lower elevations, less than 21,000 feet, but at a much higher latitude in Kashmir territory. There are so many uncertain factors, such as the impossibility of waiting for any length of time for a change of weather at the highest camp; strength of wind; cloud and snow and mountain sickness, which will prostrate a whole party at [illegible] feet (Baltistan and Ladak).

A few remarks may be made on what there is to do. Accurate comparison should be made between the very typical glaciers of this far southern section of the Himalayan range and those in Kashmir territory and the Alps, on both of which much has been written. The accompanying illustration (Fig. 1) shows the rugged pinnacled surface, caused by difference in temperature between 28° latitude and that of Kashmir some 6° farther north, where the accumulation of both snow and moraine is so similar to that in the Alps. Around Mount Everest all is changed: its height and isolation alter all the usual conditions, even those of denudation. It is desirable to know the thickness of the glaciers, the stratification, rate of motion, how far the moraines extend, and to what extent rocks *in situ* show the effects of past glaciation. Among the members of this very large expedition some should take such observations and fewer be engaged in finding what height a man can reach with or without oxygen.

FIG. 1.—Mount Everest from the Rongbuk Glacier, nine miles north-west.
From "Mount Everest" (slightly reduced in width from the illustration facing p. 214)

The extent of the moraines at the base of Mount Everest tell something of its history. They would be the same age approximately as those I have observed farther east on the south face of the Himalaya in Bhutan and on the Assam Range, with the elevation of which Everest is closely connected. Since late Pliocene time enormous disturbance and crushing on the Tibetan plateau has taken place, disturbance well displayed in the Naga Hills, on the Burrail range, where the whole thickness of the Tertiary rocks, from the base upwards, is seen elevated to 10,000 feet, resting unconformably on a much older formation. How much and how often has the course of the Arun altered, and with it the Tsauspu, in that, geologically speaking, short lapse of time? Mr. Mallory describes this basal area and the surface of the Rongbuk Glacier, comparing it with his knowledge of the Alps. I am led to quote him (p. 192): "The glacier is prostrate, not a part of the mountain; not even a pediment, merely a floor footing the high walls. At the end of the valley and above the glacier Everest rises not so much a peak as a prodigious mountain mass." The party—put at 12 Europeans, 500 mule-loads, with number of coolies unknown—is to me, who worked long ago, huge, and out of all proportion to what has to be achieved, particularly as the first year's work has been so well told, the survey and geological work

so well done. The oxygen apparatus had much better have been left out, and experiments made on some more accessible peak. Never yet used under natural conditions at any elevation, it is complicated, and as four bottles weigh 32 lbs., impossible to work, for it seems to me the surveyor or climber carrying it would be unable to use his eyes or observe anything at the most critical time and under the most critical conditions.

I conclude with some remarks on the nomenclature of peaks. In the pages of the book and on Map 2, a large-scale one of Mt. Everest, constructed at the Royal Geographical Society, are the names Pumori, Ri-Ring, etc. In the May number of the *Alpine Journal* these, eleven in number, are explained (p. 228) in a contribution by Mr. Arthur R. Hinks, secretary of the R.G.S. They are all fictitious, and after all that has been written on the subject of nomenclatures I cannot too strongly condemn their creation, although they have had the criticism of Sir Charles Bell. Henceforward it will be no longer possible to distinguish between a *bona fide* Tibetan name and these inventions, unless as is adopted in natural history, the name of a species is followed by the name of its describer. The English names of Conway, Bullock Workman, and Dr. de Filippi, such as "Ogre Peak," "Mitre Peak," "The Bride," etc., are of a higher inoffensive order, and I for one see no reason why they should not be accepted. Will these new-coined names please the Tibetans, lay or sacerdotal? They may possibly give offence. Should we as a nation be pleased to see some foreign power mapping this country and giving names to our hills and valleys? I now come to the last name assigned to Mount Everest, "Chomo Lungma." It is not a happy one for a peak though quite correct in the passport issued by the Dalai Lama's Prime Minister, and very applicable to the country, a series of valleys round the great peak, which the Expedition was to work in. Lungma and Lungpa is a common name for a valley from Scardo eastward, and on Sheet 29A, N.E. of part of Baltistan and Little Tibet will be found a similar name, "Chogo Loongma," for the great glacier valley which ends at Arundo. Substitute "Chomo," feminine prefix (goddess) for "chogo" (large), there is a close resemblance, but neither is applicable to the summit of a mountain.

I am glad the Survey of India did not rush at the discovery of this name and adopt it. Mallory thus records on p. 225: "In the Sahib's tent that night there took place a long and fragmentary conversation with the headman, our sirdar acting as interpreter. We gained one piece of information: there were two chomolungmas," that is, valleys. Every valley has its name in Tibet, where they go with their flocks and herds, but peaks are not so universally noticed and distinguished. While the R.G.S. is publishing on maps new names for Himalayan peaks, I notice comparison with Peak K2 occurs on p. 309. This, the second highest peak in the Himalaya, received the name of Godwin-Austen. At a meeting of the Royal Geographical Society, when Lieut. Younghusband read his paper, "From China through Tibet to Kashmir," I was present, and pointed out, on a large-scale plan I had prepared, the great size of the Baltoro Glacier and the position of the great peak near the source. Then followed the proposal of General J. T. Walker, R.E., the late Surveyor-General of India, under whom I had served, seconded by Sir Henry Rawlinson, president, in the chair, put to the meeting and carried unanimously. It was a great honour, an unexpected recognition of my survey work, and was deemed worthy of notice, appearing in a short time in the "Times Atlas" and in a German one. By degrees the R.G.S. has discarded my name; this book does the same; geographical record is wiped out, and leaves me to regret I was present that evening. The Indian Survey, carrying out rules of their own, correctly recognise no other name than Mount Everest; for the rest they must be of true native origin.

H. H. G.-A.

The Early Metal Ages in South America.

The Copper and Bronze Ages of South America. By Erland Nordenskiöld. (Comparative Ethnographical Studies, 4.) Pp. viii + 197. (London: Oxford University Press, 1921.) 18*s.* 6*d.* net.

THERE has long been felt the want of a general summary of information relative to the employment of copper and bronze in South America, and Dr. Erland Nordenskiold's volume will be welcomed as, to a great extent, filling the gap. In about 200 pages he has brought together a considerable mass of detailed information derived from the historical record, from representations of metal objects on textiles, pottery, etc., and from the actual implements and ornaments of copper and bronze. He discusses the problem from a variety of points of view, each chapter dealing with a particular line of inquiry.

The chronological horizons of S. American antiquities are as yet, unfortunately, insufficiently defined, and much spade-work will be required before the sequence of cultures and their relationship to one another can satisfactorily be established. The author, in dealing with this aspect of the inquiry, has made use of such evidence as is to hand and offers deductions which are often very suggestive, especially when the chronological evidence is correlated with the data derived from the study of geographical distribution of types, to which Dr. Nordenskiöld has devoted special attention.

Perhaps the most valuable portion of the present volume is that which is concerned with the chemical analyses of the metal objects. A considerable number of analyses of implements, weapons, and ornaments, the basic material of which is copper, is now available, and comparisons can be made of the percentages of tin combined with copper to yield different qualities of bronze. From the data supplied it will be seen that in the New World bronze objects the proportion of tin to copper varies exceedingly. In some instances it is so small as to make it doubtful whether the alloy can be intentional; and, in such cases, it may, perhaps, be legitimate to include the objects in the category of "pure copper." In others an unusually high percentage of tin is revealed (55·60 per cent. having been recorded by Ambrosetti in one chisel), though frequently it is the ornamental objects which contain a high proportion of tin. As Dr. Nordenskiöld points out, from the results of experiment, copper with a *slight* admixture of tin can be hardened effectually by hammering. In fact, for the manufacture of implements designed for hard usage (cutting tools, etc.) a relatively low percentage of the alloy, combined with the process of compacting the metal by hammering, seems to give the most satisfactory results. The hardness of various objects of copper and bronze was tested experimentally with a Brinell press, and the tests were applied to different parts of the same implement, the results showing that the edge was hardened more than the rest, as might be expected.

It is clear from the capriciously variable percentages of tin that the alloying of copper with this metal was not fully understood, and that the metallurgy of bronze was still for the most part in an experimental stage in South America.

The author endeavours to prove that throughout the territory of the Inca empire the Bronze-age was preceded by an age of pure copper. He makes out an interesting case, but this point can be settled finally only by stratigraphical evidence. Much of the argument is based upon typological classification and geographical distribution of types, which, together with analyses of the metals, form a powerful combination in suggesting sequences, though they cannot prove actual chronological successions.

An interesting typological sequence is afforded by certain socket axe-blades of copper, in which the decorative treatment preserves the memory of an earlier method of hafting, by means of a collar of stitched raw-hide or leather. The form of the leather collar, which suggested the socket in this type of axe, and also the thong-stitches, are realistically represented on the later copper blades, although the latter were entirely of metal and cast in one piece.

The book has suffered somewhat at the hands of both translator and printer. Several sentences are very obscure in their meaning, and misprints and other blemishes are unduly abundant. Such an expression as "bronze (pure copper)" surely should not occur in a treatise which aims at differentiating between the alloyed and the pure metal. This expression occurs more than once and tends to obscure the issue and weaken the argument.

In spite, however, of the avoidable blemishes which occur in this translated version, the book is of real value and throws light upon a very interesting archæological problem. The volume is profusely illustrated, though the figures are of unequal merit, and contains maps and tables which are very helpful. There is also a bibliography. HENRY BALFOUR.

A Monument to a Master Chemist.

Untersuchungen über Kohlenhydrate und Fermente II. (1908–1919). Von Emil Fischer. Herausgegeben von M. Bergmann. Pp. ix+534. (Berlin: J. Springer, 1922.) Germany, 186 marks; England, 22*s*. 6*d*.

IT is an accepted fact in art and literature that, apart from the vagaries of fashion, only a future generation can properly assess the ultimate fame of artist or author. This is no doubt equally true in science, yet we are already sure that time will only serve to enhance the reputation of Emil Fischer. The remarkable official account of his life and work, written for the German Chemical Society by Kurt Hoesch, and the biographical fragment "Aus meinem Leben" left by Fischer himself, afford a unique store of material: when properly digested in this country by those competent to understand it, this should make it possible to obtain a clear view of his personality and attainments which will be free from the natural patriotic bias of his own countrymen.

During his lifetime Fischer, who was not without a characteristic strain of personal vanity, issued in book form reprints of his work on the sugars, proteins, purins, and tannins, including in the first papers published up to the end of 1908. Dr. M. Bergmann, a very loyal fellow-worker, has now collected the later sugar papers from 1908 onwards. To workers in this field, the advantage of possessing these volumes is very great, and science owes a debt of gratitude to Dr. Bergmann for completing them.

The sugars were Fischer's first love, though not the subject of his earliest work; to his work with phenylhydrazine he owed the chronic illness which had so great an effect on his daily life, causing him for a time to abandon their study, first for that of the de-

rivatives of purin—the mother substance of uric acid—and later of the proteins, thereby opening the door to almost a new branch of organic and physiological chemistry. Even in 1908, when he compiled the first set of reprints of his sugar work, he expressed the fear that this sensitiveness to phenylhydrazine would prevent him from taking any further active part in developing the chemistry of the sugars. Fortunately for posterity the old love proved too strong, and he returned again and again to the fray, the result being that forty-six additional essays chronicle the work achieved.

The writer had the good fortune to come under Fischer's tuition at the time of the opening of the new chemical laboratories in the Hessische Strasse in Berlin, and to be intimately associated with him during nearly three years, carrying out sugar inquiry under his inspiration, although at this time all other workers in the laboratory were busily engaged in the early stages of the great investigation on amino acids and proteins. Viewed from the perspective of twenty years later, it would seem that Fischer was already at that time a tired man, feeling both the strain of the work involved in obtaining and designing the new laboratory and the distraction caused by the heavy burden of official duties, which he never relished but could not avoid. Hoesch now throws much light on the events behind the scenes just before this period, as the provision of the new laboratory, made the first condition of Fischer's going from Wurzburg to Berlin, eventually took seven and a half years. His account includes the statement that at one time Fischer even seriously considered leaving Berlin and going to Bonn.

Apparently from the time he came to Berlin, as successor to Hoffmann, Fischer lived only for his work, and withdrew more and more within himself as the years passed. A widower, with his sons still young, he had no one to draw him out of himself in private life; he seemed to lose the power of unbending to his associates, although he was worshipped by his laboratory companions.

Having achieved the first synthesis of a natural sugar, glucose, Fischer's greatest ambition was to make ordinary cane sugar in the laboratory, and in 1900 this problem was again attacked with all the resources of the new laboratory. At first some measure of success was attained, as complex sugars (disaccharides) were obtained, identical or isomeric with some of the natural materials. The problem of the synthesis of cane sugar itself defied solution, however, and a measure of the difficulty of the subject is afforded by the fact that to-day, twenty years later, we are apparently no nearer success, in spite of the great progress made in other sections of carbohydrate chemistry.

The difficulties of synthesising natural and artificial glucosides were fully mastered, nearly half the papers published since 1908 dealing with this field of inquiry. These include the recognition of a third form of methylglucoside, the existence of which was concurrently demonstrated by Irvine in this country. This form, which apparently contains a γ-oxide ring, is highly active, and according to later work of Haworth, it may be the form in which the fructose molecule is present in cane sugar, for which Haworth accordingly suggested a new formula. The writer is not aware that Fischer expressed his views anywhere as to the correctness of Haworth's work; it cannot but have inspired him to renewed experimental effort to effect the much-desired synthesis.

In a dozen of the later papers are described results of the investigation of the acyl derivatives of the sugars, while a like number deal with mutations within the sugar molecule leading to the formation of substances such as glucal. The results serve to show that the chemist has still much to learn about this remarkable group; but they are too complex to be considered here.

Fischer's early work on enzymes is an acknowledged classic contribution to biological science. He returns to the subject in the last paper in this collection, dated July 14, 1919, a day before his death: this contains additional data for the discussion of the all-important question of the influence of the structure of β-glucosides on the activity of emulsin. It is written in Fischer's usual simple style—he used to dictate his papers while moving about the room in a very restless state—and shows how to the very end he retained his clarity of mind. A future generation alone can decide whether he should not be regarded as the greatest organic chemist the world has yet known.

E. F. ARMSTRONG.

American General and Economic Geology.

A Text-book of Geology. By Prof. A. W. Grabau. In two parts. Part I.: General Geology. Pp. xviii+864. Part II.: Historical Geology. Pp. viii+976. (London: G. G. Harrap and Co., Ltd., n.d.) 64*s.* net, two vols.

The Economic Aspects of Geology. By C. K. Leith. Pp. xvi+457. (London: Constable and Co., Ltd., 1922.) 18*s.*

(1) PROF. AMADEUS GRABAU, who is now professor of palæontology in the University of Peking and palæontologist to the Geological Survey of China, is the author of several excellent American geological text-books, and his new "Text-book of

Geology," in two volumes—one with the sub-title "General Geology," and the other with that of "Historical Geology"—supports his reputation. His work is marked by a logical arrangement of his material and a clear and interesting statement of the main problems. His teaching has been exceptionally wide in its range, as he was first lecturer in mineralogy at Tufts College, then professor of mineralogy and geology at the Rensselaer Institute, and afterwards professor of palæontology in Columbia University, New York. He has therefore had to teach both the physical and biological sides of geology, and he writes on both with sound knowledge and judgment.

The course of study Prof Grabau recommends is to begin with the necessary elements of chemistry and mineralogy; then pass to the igneous rocks and volcanic action; next to take the "aqueous rocks"—which he limits to those formed as chemical precipitates, excluding those due to the mechanical action of water—and the organic rocks. Then follows the examination of the processes of erosion by wind, water, and ice, and by organic agencies; and after this work has been dealt with he proceeds to their products, the clastic rocks. The materials of the earth's crust having been studied, the course proceeds to the deformation of the rocks of the earth's crust by fold and fault, and to metamorphism and the rocks made by it, and concludes with the sculpturing of the earth's surface. This scheme, according to Prof. Grabau, is unusual in America, the physiographic section of the subject being usually taken first, but though that arrangement has no doubt great advantages in secondary schools, and in the popular presentation of geology, the author's course, beginning with the primary rocks and their constituents, seems to be the most logical for advanced students, and is adopted in some British universities.

The second volume deals with historical geology, and is the section in which the author's previous work renders his opinions of most interest and weight.

One striking feature of the book is its wealth of illustrations, which in the two volumes number 1980. Some of the most original are diagrammatic sections explaining the migrations of faunas, and they show that colonies have often played an important part, though not on the lines of the hypotheses which led to this process having been so long held in well-justified distrust.

One interest of such a general text-book is its evidence as to progress towards international agreement in terminology and theory. Prof. Grabau's classification of the pre-Cambrian rocks shows that their nomenclature is still chaotic. In the names of the geological systems he regretfully uses the adjectival ending of "ian," as in Cambrian, as a concession, but he thinks the ending in "ic," such as "Cambric" will ultimately be adopted. He quotes the use of the term *caldera* for an explosion crater like Krakatoa, and uses the term *sink* for a hollow due to subsidence for which *caldera*, the Spanish word, or its English equivalent, *cauldron*, has prior right. His chapter on vulcanism is illustrated by an excellent map of its distribution, but the Cameroons volcano should not be entered as extinct. The chapter on petrology makes no use of the American system, and the author's conservative classification will probably be found generally convenient for students of the standard for which the book is intended. The view that the temperature of the centre of the earth may be 200,000° or 350,000° F. is far in excess of the more moderate temperature suggested by the probable high thermal conductivity of the barysphere.

The author discusses the cause of former glaciations, and considers that none of the theories is wholly satisfactory. He objects to the theories based on variations in composition of the atmosphere, on the ground that their effects should be world-wide, whereas the glaciations have been local. Apparently he seems most disposed towards a theory of the shifting of the poles, though recognising the weight of the mathematical objections. He gives a diagram showing how the movements of the North Pole into Greenland would explain the glaciation in North America and north-western Europe combined with the contemporary freedom of Asia from ice. As a palæontologist taking especial interest in historical geology, his views on the changes and positions of the ocean are of weight. He admits great movements of the seas, but considers that in the Palæozoic period both the Atlantic and the Pacific were shallow oceans; he represents most of the Atlantic as having been occupied by sea in the Cambrian He discusses at some length prehistoric man, and adopts dates in years for him as if they were well established, but he is more cautious in his reference to Piltdown man than some of his co-patriots when dealing with the possibility of the skull and the jaw belonging to the same individual

(2) Mr. C. K. Leith's book on the economic aspects of geology contains many features of special interest. The central part of the book consists of brief descriptions of the chief ores and economic minerals, of their industrial uses, geological features, and mode of formation. The terseness of the descriptions makes them all the more convenient for those who desire a synopsis of the classification and formation of the chief economic minerals. The classification places pyrites amongst the group of fertilisers. This unusual arrangement is due to pyrites being largely used for

sulphuric acid in the manufacture of superphosphate. The book discusses some general problems which are not usually dealt with in geological text-books; thus there is a chapter on the world production of minerals, the capital value of the mineral reserves, and the political and commercial control of minerals. The last chapters deal with the relation of the geologist to the exploration and development of mineral deposits, the valuation and taxation of minerals, and mining law.

The discussion on this question includes the author's opinion of the much controverted Apex Law, wherein the mining laws of the United States and Rhodesia differ from those of the rest of the world. Mr. Leith says of the American geologists and engineers that "almost to a man they favour either modification or repeal of the law"; but he recognises that as it has been in force for 50 years, so large a body of vested interests has been established under it that it would now be difficult to make serious changes in it. He remarks on the objections to the present system of the use of expert evidence in law courts and the apparent advantage of selection of experts by the Court instead of by the contending parties; but he thinks the present system on the whole preferable, as the Court might find a sound selection impossible. The intense competition in such inquiries leads to the most intensive study of the problems. The author considers that few scientific treatises on economic geology contain facts better established than the reports of the great cases that have been rendered necessary in America by the imperfections of the Apex Law.

The author's conclusions as to the conservation of mineral resources are that little is to be feared from the actual shortage of supplies, but that the difficulties will arise in their extraction and distribution at a rate adequate to meet the future demand. He explains the use of geology in the late war and discusses the international problems based on mineral resources, which he represents as now in such confusion that it will take the combined efforts of the various governments many years to bring them into order. He says the entire European coal situation is in a state of chaos, and that, "unless there is a miraculous recovery and development of Germany's coal industry, impossible conditions have been imposed."

The volume concludes with chapters on the training of the economic geologist and on the ethics of his profession. The author recommends that the intensive study of geology should be a post-graduate course, that the universities should not give degrees in economic geology, but should leave the maintenance of a high standard, both of knowledge and conduct, to the professional societies connected with geology and mining.

Our Bookshelf.

British Labour: Replacement and Conciliation 1914-21: *Being the Result of Conferences and Investigations by Committees of Section F of the British Association.* Part 1, on Replacement, Co-ordinated and Revised by Miss L. Grier and Miss A. Ashley; Part 2, on Conciliation, Edited by A. W. Kirkaldy. Pp. xxxv+266. (London: Sir Isaac Pitman and Sons, Ltd., 1921.) 10*s.* 6*d.* net.

AN attempt has been made in the volume under notice to "sum up and co-ordinate" the various reports, issued between 1915 and 1920 by the Economic Section of the British Association, and relating to problems of labour during war time

In the first part of the volume, Miss Grier and Miss Ashley have succeeded admirably in their rather difficult work of collation, and the result is to present in small compass a concise history of the industrial adventure of women during the period of the war. The outlines of the story are by now sufficiently familiar: the value of the present contribution lies in the rich store of material, partly statistical, which it offers, and in the conclusions it reaches regarding the future of women in industry. The moral of the story is that while war-time experience has left women more ready to offer their services in production, there has been little permanent modification of industry which would make it possible to utilise those services.

Part 2 of the volume, dealing with conciliation in British Labour, 1914-1921, is somewhat inchoate. It is practically a reprint of reports on the promotion of industrial harmony and on industrial unrest, which had already been published elsewhere, and there is little evidence of selection from the papers and speeches which make up the original reports. Some excision and co-ordination would have added to the permanent value of this section.

The last forty pages of the volume contain a sympathetic discussion of works committees by Mr. C. G. Renold, who deals, with much breadth of vision, with the problems of industrial management involved in the growth of these committees.

Royal Society. Reports of the Grain Pests (War) Committee. Nos. 1 to 10 (in 1 volume). Pp. 23+48(+11 plates)+18+20+10+51+52+28(+11 plates)+52+16. (London: Harrison and Sons, 1918-1921.)

THE Grain Pests (War) Committee was appointed by the Council of the Royal Society in June 1916, as the result of correspondence with the Board of Agriculture, in which the Board requested the Royal Society to appoint a committee "in relation to the damage done to grain by insects." When established, the committee at once took very active measures to carry out the work allotted to it, and published the results of the investigations which it initiated in a series of valuable reports. Most of the latter have already been noticed in our pages and need no further comment. These reports have now been issued in book form, together with a final brochure (Oct. 1920), drawn up by the chairman, Prof. W. A. Herdman, who has summarised the results of the researches and puts forward certain

recommendations as to future work. The findings of the committee have shown clearly that the whole subject of grain pests is one of great importance to the Empire, and it is recommended that the State should assume a general responsibility for the continuance of the investigations. It is obvious that, if the work is to be placed on a permanent basis, it must be sufficiently provided for in order that it may be carried to its logical conclusion—the practical control of grain pests. The recommendations made for the provision of a nucleus organisation do not involve any large expenditure of money and, in view of the great importance of the conservation of food-stuffs, it is earnestly hoped that the Government will see its way to establish the work along lines suggested by this committee.

A. D. IMMS.

Among Primitive Peoples in Borneo: A Description of the Lives, Habits and Customs of the Piratical Head-Hunters of North Borneo By I. H. Evans. Pp. 318. (London: Seeley, Service and Co., Ltd., 1922.) 21s. net

THE part of Borneo described by Mr. Evans is that which is under the control of the British North Borneo Company, and the peoples with whom he deals are three in number: the Dusuns, an Indonesian people speaking a Malayo-Polynesian language, who inhabit the interior; and the Bajaus and Illanuns, immigrants of Proto-Malayan stock who live on the coast. Mr. Evans is a careful observer, and his experience as an official of the company enables him to speak with authority. On many points he is able to correct or supplement our previous information. The peoples he describes present marked contrasts, both in temperament and in culture. The Dusun is an agriculturist, in the main industrious, living in independent village-communities, each under a headman. In religious belief he is an animist, and has a strong and abiding faith in omens. The coastal peoples, on the other hand, are indolent and inveterate gamblers, who, now that their former chief industry—piracy—has been suppressed, earn their living from the sea. They are Mahommedans, but lax, and their religious beliefs embody many survivals of primitive beliefs, of which, unfortunately, Mr. Evans had opportunity to collect only a few examples.

The Island of Roses and her Eleven Sisters: or, the Dodecanese from the Earliest Time down to the Present Day. By Dr. Michael D. Volonakis Pp. xxv+438. (London: Macmillan and Co. Ltd., 1922). 40s. net.

IN this volume the author gives an account, both historical and geographical, of the twelve islands lying off the western extremity of Asia Minor, for which the term "Dodecanese" has become current since the Italo-Turkish war. Of these, the most important is the island of Rhodes, but to English readers the names of others, notably Patmos, associated with St. John and the Book of Revelations, and Cos, the home of Hippocrates, will be equally familiar. The author, himself a native of the Dodecanese, relies mainly upon literary sources, but has supplemented these by the evidence of archæology and numismatics, while his intimate local knowledge has proved invaluable in elucidating his authorities. Owing to the isolation of their insular position, the inhabitants, while taking part in times of crisis in the affairs of mainland Greece, have kept their institutions practically intact from a remote period, notwithstanding successive waves of invasion, and subjection to the Knights of St. John, the Turk and the Italian. Hence this description of the islands has a peculiar value, and the author's fuller account of their archæology and culture here promised will be awaited with interest. The book is exceedingly well illustrated by numerous photographs.

The Machinery of the Mind. By Violet M. Firth. Pp. 95. (London: G. Allen and Unwin, Ltd., 1922.) 3s. 6d. net.

IT is stated by the author that this volume is for the edification of those who have neither the time nor the training necessary for the study of standard texts.

Whether such readers will be in the position, at the end of its perusal, to apply its generalisation to the interpretation of their own problems, or be inspired to continue the subject, is doubtful. In less than one hundred pages the author disposes of some of the most fundamental and debatable problems of modern psychology, but naturally there is no clue to their debatable character. It may be possible to compress the general truths of some sciences into a few pages, but none of the biological sciences are in that position, and psychology least of all. In a few lines the technical terms, sensation, percepts, concepts, images are used but not explained, while complex is used in two different senses. Analogy is useful in its place, but is very much over-used here: nor is it scientifically sound to give as evidence in a later chapter what has been merely asserted in an earlier one. In short this book is little more than an expanded dictionary of some frequently used psychological terms with the drawback that the order is not alphabetical.

Human Traits and their Social Significance. By Dr. Irwin Edman. Pp. xii+467. (London: Constable and Co., Ltd., n.d.) 15s.

THE work under notice is designed to serve as a general introduction to the problems of contemporary civilisation. The author feels that in attempting to interpret the conditions of life under which we live the psychological point of view is too frequently overlooked, and yet it is most important. Following Dr. McDougall and Prof. Thorndike, he describes the fundamental activities which are man's endowment, his primitive instincts their environmental modification and development, the individual difference in endowment and the part played by language. While emphasising the innate character of many of man's actions and aims, the author realises that there is also in man the power to reason and to put before himself ideals which he considers desirable; such ideals when embodied in social customs, institutions, and speech become powerful motives.

The style is clear and the whole book is easy to read and should prove of value to the historian, economist, and the student interested in the complexities of life. The subdivision of each chapter, however, into paragraphs with a heading in heavy type seems unnecessary and is a hindrance rather than a help.

Problèmes et exercices d'électricité générale. Par Prof. P. Janet. Pp. vii+254. (Paris: Gauthier-Villars et Cie, 1921.)

PROF. JANET gives an interesting collection of problems which have been set in the entrance examinations for the Higher School of Electricity in Paris. Many of the problems are novel, and in some cases it is shown how the solution can be obtained by several different mathematical methods. The examples are purely theoretical, so exact solutions can be given. They are expressed in nearly every case by algebraical formulæ, numerical illustrations being left to the student. The English reader will find the latter part of the book very instructive, as the author frames his problems so as to take into account mechanical as well as electrical considerations. For example, the instantaneous values of the currents depend on the moments of inertia of the moving parts of the machines as well as on the inductances of the circuits. We hope this innovation will be followed in English text-books. The students are supposed to have a thorough knowledge of electrical principles and to be familiar with the calculus. We can recommend this book to teachers. A. R.

Thought-Coin. By Bart Kennedy. Pp. x+219. (London: W. Rider and Son, Ltd., 1921.) 5*s.* net.

THE title gives no clue to the contents of this book. It is not, as might be imagined, one of those pseudo-scientific works urging a one-sided belief in the all potence of thought, nor is it a psychological treatise on thought-processes. It is an attempt to consider some of the problems of life, such as dreams, consciousness, grouping, sex, etc., not as abstractions but as living realities; it is a frank acceptance of facts as against the "oughts" and "ifs" of so many writers, and so far is more truly scientific than some of the more apparently scientific books. The author surveys the universe with the vision of the seer, and gives to problems which are so often treated in isolation the background of relation to the universe. All life is for him an ever provocative mystery. He writes with a penetrating imagination, but imagination controlled and vitalised by the teaching of science. It is interesting to read scientific problems expressed in terms of imaginative literature.

The Evolution of Consciousness. By A. W. Tilby. Pp. 256. (London: T. Fisher Unwin, Ltd., 1922.) 15*s.* net.

MR. TILBY writes with a vivacity and humour which make his book exceedingly pleasant reading. It contains no original research, but it is exceptionally well-informed. The idea is outwardly very like that of Bergson's creative evolution, and may have been suggested by it—that consciousness in every form, instinctive and intellectual, is a product of the evolution of life and utilitarian in its purpose. There is an essential difference, however, in the fact that Mr. Tilby recognises no interpretative principle such as that which, for Bergson, makes evolution creative. All that is, Mr. Tilby tells us, has emerged in a definite historical sequence, and we have merely to accept the fact and not ask why. The inert we are led to understand preceded the living, and even memory is a purely material fact.

F. C. Donders. *Reden gehalten bei der Enthüllung seines Denkmals in Utrecht, am 22. Juni* 1921. Von Prof. Dr. C. A. Pekelharing, Dr. Sikkel, Dr. A. F. Baron van Lijnden, Dr. J. P. Fockema Andreæ; aus dem Holländischen übersetzt von Paula Krais geb. Engelmann. Pp. 62. (Leipzig: W. Engelmann, 1922.) Fl. 1.

THE unveiling of a statue of F. C. Donders last summer at Utrecht was the occasion for the delivery of several addresses on his life and work. These have been collected, translated into German and issued as a small illustrated booklet. Donders was the founder of modern teaching on the accommodation and refraction of the eye, his great work on which was published in 1864. He was a prolific writer, and a list of his papers (1840–1883) is included: some of his latest contributions deal with colour-blindness.

The Microscope: A Simple Handbook. By Conrad Beck. Pp. 144. (London: R. and J. Beck, Ltd., 1921.) 2*s.* 6*d.* net.

MR. BECK has in this little book collected and set out in elementary form a considerable amount of information useful to the microscopist. The optics of the instrument are described in a simple manner, and a final chapter deals with pond-life as objects for the microscope. Published by Messrs. R. and J. Beck, the book avowedly deals with the products of that firm, but is none the worse for that so long as the reader is aware that other makers of microscopes exist. We can commend this account of the microscope to the beginner, who will find in it clear directions for use and explanations of many difficulties.

R. T. H.

Reports of the Progress of Applied Chemistry. Issued by the Society of Chemical Industry. Vol. 6, 1921. Pp. 638. (London: Society of Chemical Industry, 46-47 Finsbury Square, n.d.) 7*s.* 6*d.* to Members; 12*s.* 6*d.* to Non-members.

REFERENCE has previously been made in NATURE to the very useful annual reports issued by the Society of Chemical Industry. This year the report is of the same high standard as its predecessors. A particularly noteworthy feature of the separate reviews of the progress made during the year, each written by a specialist, is that the matter is treated critically. The reports are essential to those who wish to follow the progress of chemical industry, and should be in the hands of technical chemists, teachers, and students, all of whom will find matter of interest in them.

Practical Polishing and Staining. By A. W. Parkhouse. Pp. viii+120. (London: Benn Bros., Ltd., 1922.) 8*s.* 6*d.* net.

MR. PARKHOUSE writes from practical experience, and his book is a very readable and well-informed account of the subject. He very properly lays stress on the importance of close co-operation between the polisher and the cabinet maker, and his book may be recommended to both.

The Intensity of X-ray Reflection.

IN a letter on "The Intensity of X-ray Reflection from Powdered Crystals" (NATURE, July 8, p. 38), Prof. A. H. Compton and Mr. N. L. Freeman have described some measurements which they have made on the reflection of X-rays by rock-salt, and have compared their results with figures published by us in the *Philosophical Magazine* for July 1921. Quantitative measurements of the amount of radiation reflected by the crystal are of great interest, since it is probable that an estimate of the way in which the electrons are distributed throughout the atom may be based on them.

In the case of the reflection by the (100) planes of rock-salt, they find a large discrepancy between our figures and theirs. The point at issue may be put as follows. By comparing the incident and reflected monochromatic X-ray beams, and applying formulæ calculated by Darwin and others, it is possible to estimate the amount of X-ray energy scattered by an atom in certain directions in terms of that scattered by a single electron under the same conditions. As the angle through which the rays are scattered is increased, the amplitude of the diffracted wave falls off, owing to interference between the waves scattered by the electrons distributed around the centre of the atom. In the case of the (100) reflection by rock-salt, we found that at the angle at which the reflection takes place the effect of the 28 electrons in a pair of sodium and chlorine atoms is reduced to an effect 20·1 times as great as that of a single electron (p. 7, *Phil. Mag.*, *loc. cit.*). The ratio 20·1/28 is that indicated by ψ in this note by Prof. Compton and Mr. Freeman.

We obtained an estimate for ψ^2 by measurements made with a single rock-salt crystal. Prof. Compton and Mr. Freeman determined the quantity by the powder method, measuring the amount of radiation diffracted by a layer of powdered rock-salt spread on a plate, irradiated by an X-ray beam made homogeneous by previous reflection. They obtain a value of ψ^2, equal to 0·64, correct to 10 per cent., and quote our results as giving $\psi^2 = 0·43$, a much lower value.

It may well be that our estimate is too low, for the reasons given by Prof. Compton in his note, which have been fully discussed recently by Darwin (*Phil. Mag.*, May 1922). By using the powder method, the extinction effect, which increases the absorption of the rays passing through at the reflecting angle, is partly or wholly eliminated. We believe, however, that an error has been made in quoting our value for ψ^2 as being 0·43. We obtained

$$\psi = \frac{20·1}{28} = 0·718,$$

$$\psi^2 = 0·515.$$

If this be the case, the discrepancy is not so great as Prof. Compton and Mr. Freeman believe. They used the molybdenum K_α line, of wave-length 0·708 Å.U., whereas we used the rhodium K_α line of wave-length 0·615 Å.U. The value of ψ^2, however, is independent of the wave-length for a spectrum of given order.

Their estimate for the value of ψ^2 in the case of the (100) reflection is of the very greatest interest. The measurements made with a single crystal are difficult to interpret for the strong reflections, on account of extinction, though they are probably accurate for the weaker ones. On the other hand, it is just these values for ψ^2 at small angles which are of the greatest importance, as indicating the distribution of electrons in the atom, particularly in its outer confines.

Geology and the Primitive State of the Earth.

I HAVE no wish to depreciate the importance of the work of those geologists who have examined the older known rocks of the earth's crust and decided that all of them have been altered since they first became solid; but I question whether their results afford the evidence concerning the primitive state of the earth that is suggested by Prof. A. P. Coleman and Prof. G. A. J. Cole (NATURE, June 17 and July 8). The deepest boring yet made is one of 2·5 km., and there are few over a kilometre in depth; that is the extent of the crust accessible to geologists. Yet the average thickness of sediments over the continents is probably some kilometres, and in many places it is practically certain that the thickness reaches tens of kilometres. In addition, we have vast thicknesses of intrusive and eruptive rocks. Would it be surprising if all rocks in their primitive state have been denuded away or buried to an inaccessible depth?

Even if it is considered that a piece of primitive crust, still unaltered, has had an appreciable chance of being discovered and examined, I do not see that the results actually found afford any evidence for the cold earth theory as against the hot earth theory. The primitive rocks formed by slow accretion of solid planetesimals would be in a perfectly characteristic and recognisable condition; no such rock has, so far as I have heard, been discovered, and therefore Prof. Coleman's arguments, if they are sound, would be just as injurious to the planetesimal theory as to the hot earth theory.

The temperature of the surface of the earth is at present maintained almost wholly by solar radiation, and not by conduction from the interior. The rate of conduction of heat from the interior is of order 2×10^{-6} cals/cm.^{2} sec. The solar constant is about 3×10^{-2} cals/cm.^{2} sec. Even if the earth had a solid crust only a mile thick, the surface temperature would still depend wholly on the sun's radiation. Thus it would become cool at the surface at a very early stage in the solidification, and it is not surprising that the oldest rocks should show evidence of water at the surface.

I have published in the Monthly Notices of the Royal Astronomical Society, vol. 77, 1916, pp. 84-112, and in the Proceedings of the Royal Society, vol. 100, 1921, pp. 122-123, arguments that I believe to be fatal to the form of the planetesimal hypothesis that attributes to solid planetesimals any cosmogonical importance, and postulates an earth that has always been solid. No supporter of this hypothesis has yet published any reply to, or acknowledgment of, these criticisms.

α-Particles as Detonators.

THE observation recorded by Mr. Henderson in a letter to NATURE of June 10, under the above heading, appears to involve possibilities of the greatest prac-

tical importance. Mr. Henderson found that under suitable conditions an α-particle may cause the detonation of nitrogen iodide, about one α-particle in 10^7 or 10^8 being effective. He suggests that other unstable substances may be similarly affected The question naturally arises as to whether any of the explosives commonly used are sufficiently unstable to be detonated in this way As they are all very much more stable than nitrogen iodide we would expect that the chance of an α-particle causing detonation would be much smaller, so that an explosion might only occur after a lengthy exposure to a copious source of α-particles Still, in view of the almost universal presence of small traces of radioactive matter, it is possible that some unexplained explosions have been brought about in this way It would appear to be worth while to conduct an investigation into the possible effect of α-particles on various explosives and detonators If it is found that there is even the remotest possibility of detonation occurring, precautions should be taken in the manufacture of explosives to reduce the radioactive contamination to the lowest possible value.

Occurrence of a Crystalline Style in the American Slipper Limpet (*Crepidula fornicata*) and its Allies.

DURING recent investigations, carried out with the aid of a Government grant, on the oyster beds in the river Blackwater, freshly caught specimens of the American slipper-limpet (*Crepidula fornicata*) were examined fresh microscopically, and the interesting fact was established that this species possesses a crystalline style. Individuals which have been out of water 24 hours or more still possess remains of the style, which has undergone partial solution Crepidula differs therefore in this respect from the native oyster (*O edulis*), the style of which is frequently completely dissolved within 3 to 5 hours after individuals are taken out of water, and is completely dissolved in all specimens after about 10 hours out of water

In the style of Crepidula occasional Spirochætes (*Cristispira balbiani*?) were seen, but not identified By analogy it was suggested that the allies of Crepidula should also possess a crystalline style, and an examination of fresh specimens at Plymouth at once proved the surmise correct in the case of the species *Calyptræa chinensis* and *Capulus hungaricus* It is highly probable, therefore, that a crystalline style is present in the whole of the Calyptræidæ and the Capulidæ, it is also not improbable that a style may be present in all sedentary non-parasitic Streptoneura

I have long suspected that a crystalline style—particularly in molluscs—is associated with a mode of feeding which consists essentially in the capture of planktonic organisms by mucus controlled by harmonised ciliary mechanisms The discovery of a crystalline style in Crepidula and some of its allies, which all feed in the manner mentioned, lends some support to this idea; but too little is known of the habits of other gastropods which definitely possess a style, to permit of a general correlation of the presence of style with capture of food by means of mucus. Some indications have been obtained by rough hurried experiments that the style substance is a good solvent for mucus; and if this observation can be confirmed it may well be shown that the dissolving of the mucus enveloping food-masses is one of the most important functions of the crystalline style.

Sense of Smell in Birds.

IN the issue of NATURE for June 17 there is a discussion on the inadequacy of present observations on the sense of smell in birds Perhaps the following notes would be of interest. They are from an account of the habits of the birds of Trinidad which will be published shortly by the Department of Agriculture of that island

On September 20, 1918, I observed large numbers of the black vulture (*Cathartes fœtens*) collected on and round a field which had recently been experimentally manured with liquid slaughter-house refuse and could be smelt a quarter of a mile away, although nothing was visible to the eye A few red headed vultures (*Cathartes aura*) were also present. In Panama the same birds quickly found the body of an animal that I put close to the trunk of a thick tree, quite invisible from above

Still more interesting is an observation by Hart (Bull Dept Agr Trinidad II, p 155), who records that *Cathartes fœtens* used to collect in the morning hours on trees near a plant of *Aristolochia gigas* v *sturtevanti* which was flowering, and which has a particularly strong odour There can be no doubt that these birds have an efficient sense of smell. At the same time I think that their congregation in numbers is due to watching the movements of their neighbours

C B WILLIAMS.

Ministry of Agriculture, Cairo, Egypt,
June 29.

The Skull of Sir Thomas Browne.

IT may be known to some readers of NATURE that the skull of Sir Thomas Browne has recently been reinterred at Norwich, but that previously it came to London, where careful measurements, drawings, and tracings of it were made It is proposed to publish a full account of the skull in *Biometrika*, but it would add much to the interest of the proposed monograph if it were accompanied by a series of reproductions of the portraits and engravings of one of the most noteworthy of Englishmen who have combined the study of medicine with the pursuit of literature

The large number of plates required to illustrate adequately the relation of the skull to the portraits renders—under the present conditions of both printing and illustrative work—the appearance of a complete monograph, such as we desire to see issued, very difficult We propose, therefore, to issue one hundred copies of the monograph at the price of one guinea each, if lovers of Sir Thomas Browne can be found in adequate numbers to subscribe for copies. Will you kindly permit us to appeal through your columns for the names of those who are willing to aid in this scheme for putting on permanent record the physical aspect of the author of the "Religio medici," who, by that and his other works, has won a unique position in the heart as well as in the mind of every cultured Englishman? Willingness to subscribe may be notified to either of the undersigned at the Royal College of Surgeons, Lincoln-Inn Fields, and University College, London, respectively.

ARTHUR KEITH.
KARL PEARSON

London, July 12.

Bloomsbury and the University of London.

By T. Ll. Humberstone.

BLOOMSBURY, originally Lomosbury, was in ancient days a retired village, renowned for its wholesome and pleasant air, situated with its manor near the present Bloomsbury Square. The Royal mews, established here, were burnt down in 1537, when the hawks and steeds were removed to Charing Cross. Two great houses were in the neighbourhood—Montagu House, which became the British Museum, and Southampton House, afterwards called Bedford House, near the present Russell Square. To the north, stretching towards Hampstead and Highgate, was open country with irregular patches, frequented by duellists, and the scene of robbery, murder, and every form of depravity.

Russell Square was built at the beginning of the nineteenth century, and became the resort of "gentlemen of the long robe." In those days, or somewhat earlier, Great Ormonde Street was a centre of fashion, but in course of time the district lost caste, and it was accounted a mark of high breeding not to know the locality. Croker inquired in the House of Commons, "Where *is* Russell Square?" It is recorded, however, that the dignity of this once patrician quarter of London was preserved by the ancient landladies, who still cherished the belief that Great Ormonde Street was the hub of the fashionable world.

The British Museum forms the natural centre of the district. Its establishment was due to a man of high scientific attainments, Sir Hans Sloane, a physician, who for a quarter of a century was president of the College of Physicians. He accumulated at his house in Chelsea a vast and varied collection of books and manuscripts, objects of natural history, and works of art, which he directed by his will should be offered to the nation on favourable terms. After his death, in 1753, an Act of Parliament was passed approving the acquisition of the collection, together with the Harleian Library of Manuscripts and the Cottonian Library; and to house the collections the Government purchased Montagu House, raising for this purpose, by means of a lottery, the sum of 100,000*l.*, of which 20,000*l.* was used for the purchase of the Sloane Collection. The museum was opened in 1759, and ever since has been available for "studious and curious persons," to quote the official regulations. In its gardens were encamped in 1780 the troops who quelled the Gordon Riots.

George IV.'s Library was afterwards purchased, the *Quarterly Review* spitefully remarking that women's looks were the only books His Majesty required. The present building was designed by Sir Robert Smirke. It was commenced in 1846 and cost 800,000*l.*, an amount which is worth remembering in view of the fanciful estimates of the cost of housing the University of London on the adjoining site. The dome of the library is said to be the largest in the world, with the exception of the Pantheon at Rome. The north extension is a recent addition of great architectural dignity.

The next most important building in Bloomsbury is undoubtedly University College in Gower Street, founded in 1826 to afford "literary and scientific education at a moderate expense." Tom Campbell, the poet, and Lord Brougham share the credit for its foundation. Campbell, in his letter to the *Times*, suggested that a number of the "middling gentry" in London would be prepared to pay 50*l* to furnish the inside of their skulls, that being the amount willingly paid for a full-bottomed periwig for external adornment. The College was nicknamed Brougham's "patent omnibus" as a play on the motto *Patens omnibus Scientia*. From the first, however, the ideals of the College were high and comprehensive. "May God," prayed H.R.H. the Duke of Sussex in laying the foundation stone on April 30, 1827—it should be noted that the centenary of this auspicious event is rapidly approaching—"bless the undertaking which we have so happily commenced, and make it prosper for the honour, happiness, and glory, not only of the metropolis, but of the whole country." This odour of sanctity was short-lived, for the Church party stigmatised the institution as the "Godless College," and established King's College in the Strand as an antidote. Nevertheless, the Duke's prayer has been answered; the bare fact of the inclusion of Lister's name in the list of distinguished *alumni* would be sufficient proof. After the ceremony the company dined together at the Freemasons' Tavern, thus establishing an early tradition of good-fellowship. The beautiful buildings, with the characteristic portico and graceful cupola, were designed by William Wilkins, the architect of the National Gallery.

The College is not included in the photograph, but to the north of the British Museum are to be seen the four plots recently purchased by the Government for the new headquarters of the University of London. The whole of Torrington Square and parts of Russell and Woburn Squares also belong to the University site of 11½ acres, to which it is proposed to move King's College also in the fulness of time. This is not the occasion to attempt even the briefest summary of the controversy which has raged round this question during the past eleven years. One point is, however, pertinent, as it is illustrated by the photograph. It has been charged against the site that its division into four plots is a great disadvantage. Could it not be urged with equal force that this is one of its greatest advantages? The four plots will permit of the construction of a group of well-lighted and ventilated buildings, with numerous entrances and appropriate purposes. The alternative of a mammoth single building would inevitably suffer from defects of lighting and ventilation, and would cause endless annoyance through the waste of time involved in pacing long corridors. The modern civic university must be, literally and figuratively, on the street rather than in some secluded grove. As will be seen, one of the plots is occupied by some wooden buildings, which have been acquired by the University Union Society from the Young Men's Christian Association as a temporary home. Immediately to the north is the University Institute of Historical Research, established last year for the benefit of students pursuing their investigations at the British Museum, the Public Record Office, and other archives. There they will come "to discuss their problems and results, and to receive that oral guidance for which they are properly debarred in libraries and manuscript departments." The Institute includes departments for English and Colonial history, naval and military history, the history of London, and of various foreign countries, and palæography. The plan is admittedly "opportunist rather than ideal," but the Institute may serve as a model and forerunner of numerous University Institutes for special studies. Between the wooden buildings and Gower Street is the site of the new Institute of Public Health to be established by the Rockefeller Foundation.

Bloomsbury has many interesting associations, as the plaques fixed to its houses testify. These are mostly literary or artistic, but occasionally scientific. At the Bedford Square end of Gower Street is the house where Cavendish, the chemist and philosopher, lived for some years. The house became packed with books and apparatus, and another in Dean Street, Soho, was taken as a library. When Cavendish wanted a book he signed a formal receipt. Enormously wealthy, he made no use of his money. His daily fare consisted of legs of mutton; and it is said that when his servant informed him that the one leg of mutton in the house would not be sufficient for the company, Cavendish instructed him to get another. Such simple direct answers to difficult questions are the acid test of greatness. We read also that Cavendish gave to Humphry Davy some bits of platinum for his experiments, and visited him to see the results of his experiments on the decomposition of the alkalis. He died in 1810.

While the Bloomsbury landlady, to whom respectful tribute has already been paid, remains extant, the district, as a whole, is rapidly changing in character. Russell Square and Bedford Square and the adjoining streets provide accommodation for a large number of learned and other societies of an academic character, and for several teaching institutions connected with the University of London, in addition to those already mentioned. The district is favoured by foreign consulates, the legal, architectural, and other professions, and by business concerns for administrative purposes. It certainly offers many attractions in its "wholesome and pleasant air," its nearness to the great railway termini, its dignity and traditions, its faint historical aroma, its spacious squares and wide streets. As London grows, a process which continues without rest or abatement, the importance of its central areas must be accentuated for all public and private purposes involving the visitation or meeting together of people from the environs of the city. Therefore, whatever its detractors may allege, the future of Bloomsbury is assured.

The Physiology of Life in the Andes.[1]

By J. BARCROFT, C.B.E., F.R.S.

THE recent expedition to Peru was initiated under the auspices of the Royal Society. So far as the British members were concerned, it was financed in part by a grant made by that body, in part by two substantial private subscriptions from Sir Robert Hadfield, then on the Council of the Royal Society, and Sir Peter Mackie, who has on previous occasions been a staunch supporter of anthropological research undertaken by the Royal Society. In part also its expenses were met by grants from the Moray and Carnegie funds in Edinburgh. These grants paid some of the expenses of the expedition as a whole, together with the personal expenses of three of its members—namely, Dr. J. C. Meakins, professor of therapeutics in Edinburgh; Mr. J. H. Doggart of King's College, Cambridge; and myself. The project was warmly supported by a number of institutions on the American continent, each of which sent a member of the party at its own expense Harvard Medical School was represented by Dr. Bock, Dr Forbes, and jointly with Toronto Medical School by Prof. Redfield; the Presbyterian Hospital, New York, by Dr. George Harrop; and the Rockefeller Institute by Dr. Carl Binger The American and British parties sailed from New York and Liverpool respectively in the middle of November, the American section arriving in Peru a fortnight or more before we did.

I have perhaps given the impression that the party consisted of two sections from different continents, sharply marked off from one another, and neither of which had seen the other before. This impression is erroneous, for the whole idea of the expedition grew from the fertile soil of collaboration in the researches carried out under a single roof. Dr Redfield and Dr. Bock had been working in Cambridge (England) throughout the previous year, and Dr. Harrop had been there for a short time. There the scheme had been hatched, the methods standardised, and a number of the controls carried out.

Why did we go to Peru, or, more precisely, to Cerro de Pasco? The question may most easily be answered by comparing Peru with some of the other localities to which we might have gone, and to which others have gone before us, for example, Monte Rosa, Pike's Peak in Colorado, the Peak of Teneriffe, and the Himalayas Without going at length into the merits of each, the advantages of Peru will be sufficiently apparent if I compare it to one of the above, and I will select one of which I have personal experience, namely, the Peak of Teneriffe. Peru and Teneriffe have in common the merit of being close to the sea In either case the baggage can be put on board at Liverpool or Southampton and taken to your mountain base without further transhipment. Peru, however, possesses the first necessity of laboratory equipment—an abundant supply of water—up to a height of 16,000 ft., *i.e.* 4000 ft. higher than the Peak. In the latter place the highest altitude at which I know of water is 7000 ft., while at 11,000 ft.—near the situation of the Alta Vista hut—there is an ice-cave from which water may be obtained by melting the ice.

Again, the conditions of transport are vastly different in Peru from what they are in Teneriffe. In Teneriffe everything goes up the mountains by mule. The amount of apparatus which can be taken up is therefore small; and if it arrives whole at its destination the worker is fortunate. If it arrives broken, there is little hope of mending it. We were very fortunate, at an early stage of our preparations, in getting in touch with Mr. Oliver Bury, the chairman of the Peruvian Corporation The Peruvian Corporation owns, among other railways, the trunk line which goes directly inland from Lima, climbs the Andes to a height of almost 16,000 ft., and then drops down to Oroya (12,000 ft.), situated on the pampa between the two parallel ranges of the Cordilleras. From Oroya railways run north to Huancayo, and south to Cerro de Pasco (14,200 ft.), which place was to become our principal seat of operations. To the Peruvian Corporation we owe our laboratory. For the purpose we were assigned a luggage van, 45 ft. in length, together with a goods van which we used as a store; and these they offered to take to any locality on their system at which we desired to work. While the American members of the party awaited our arrival at Lima, they fitted up the luggage van and made a very fine laboratory of it. At one side the door was closed up and windows put in its place, benches and shelves were fitted, electrical wiring was installed, and ultimately we had electric light, power, and heat. What greater contrast in efficiency could exist than between our mobile laboratory at Cerro, jacked up off the bogies to prevent vibration, fitted with X-ray plant and apparatus for the measurements of hydrogen ions, on one hand, and the Alta Vista Hut in Teneriffe, with its paraffin stoves which emitted little but smuts and barely sufficed to melt a few handfuls of ice Of more account, however, than all these advantages was the fact that, up to an altitude of 16,000 ft. in Peru there is a population most of which is connected with the mining industry This population may be divided into two categories, namely, the Anglo-Saxon officials and the native labourers. The latter are of Indian descent, and as a race have lived at this altitude for many generations In Cerro they are designated "Cholo," a name that has no exact anthropological significance, but I shall use it and so avoid an assumption of anthropological knowledge which I do not possess.

To judge from the customs which prevail in the outlying villages, the Cholo is not far removed from a very primitive civilisation. Within a mule-ride of Gollarisquisga there are communities in which private ownership of land does not exist; the land, as in some of the Russian communities which are, or were, on the Canadian prairie, belongs to the village. The produce, if the village is small, is placed in the church, in the larger villages there is a store for this purpose. If the stock of some commodity has run out, some person goes to such a market as Huancayo and buys some more, not for himself, but for the village. I said "buys"; but there are places to which money has scarcely penetrated, and where the exchange of commodities is still a process of barter. The condition of medical science in these villages may be gathered from the fact that such

[1] From a discourse delivered at the Royal Institution on Friday, June 9

nostrums as horse-dung and well-kept human urine occupy an honourable place in the pharmacopœia, and that a custom appears to linger by which, when the practitioner has done his best—or worst—and failed, the services of another official are called in. He is the "despenador" or "putter out of pain." I need say no more of his or her duties than to give the following quotation from Bensley's "Spanish and English Dictionary": "Despenadora—a woman who is supposed to push her elbow into the stomach or breast of dying persons to relieve them from agony."[1]

It seems clear then that the Cholo, not the Cholo of Cerro de Pasco or Oroya, but of some of the far outlying districts, has been little touched by the Spanish or even the Inca civilisation, and that in him we have a subject for physiological research whose like has varied little for generations. In physique he is short in stature and sallow, or with some blood in his cheeks. That part of his anatomy which was principally of interest to our party was his chest. We made a considerable number of chest measurements. As regards the chest circumference the following statement sums up our findings. We based our measurements on Prof. Dreyer's tables, accepting his estimate of the normal ratio between the trunk length and the chest circumference. We ascertained that the average circumference of the Cholo chests which we measured would normally be 79 cm. It was, in point of fact, 92 cm. As a rough check we measured our own trunk chest ratios and those of the American and British engineers, a community of fine physical development. The circumference of the Anglo-Saxons was little in excess of Dreyer's estimate. The lowest level at which we came across one of these small people with chests which appeared out of proportion to the rest of his stature was at Matucana (8000 ft.), and on inquiry we found that he was a native of Huancayo (12,000 ft.).

To pass to the more strictly physiological aspects of the work of the expedition, one must reflect that the desire to investigate mountain sickness goes back at least to the middle of the last century. It is remarkable, when one comes to think of it, how recently our knowledge of the causation of disease has grown. The lure of mountain sickness to the physiologist lay originally in the fact that it was a disease to which a definite cause could be assigned. You go a certain height up the mountain—any mountain—and when your ascent corresponds to a given fall in the barometer you suffer from mountain sickness; when you descend, the malady leaves you. Mountain sickness, or as it is called in Peru, "soroche," seemed to form a sort of opening into the ætiology of disease.

In recent years the centre of interest has to some extent shifted. The cause of mountain sickness is universally regarded as insufficient oxygen supply to the tissues of the body, though there may still be some doubt as to the directness of the connexion between the deficiency of oxygen pressure in the blood and the activity of the nerve cells responsible for the continence of food in the stomach. Interest latterly has centred rather around the methods which the body has at its disposal for adapting itself to such a condition. But the same thread still runs through the fabric; this particular instance of adaptation to environment is studied because our knowledge of the conditions with which the body has to deal are so exact and the conditions themselves so easily produced or abolished.

Partly, of course, it has another interest, namely, that imperfect oxygenation of the blood is a factor in a number of pulmonary complaints and an analysis of those complaints demands an investigation of this particular factor. That is the definitely medical aspect, of which I shall say but little. Rather I shall turn my attention to the extent to which adaptation can take place, and the means by which it is brought about.

Some of the Cholos appear at first sight to have acquired an astonishing capacity for physical effort at high altitudes. An example may be cited. Near Cerro de Pasco there is a mine worked in the old Spanish way. The ore is raised from the bowels of the earth on the backs of porters, who carry their loads up a rude staircase. The mine is about 250 feet below the surface, and the staircase about 650 feet in length. It opens under a sort of hut. The first porter whom we saw emerge was a little fellow, who said that he was ten years old. We so far doubted his word as to place his age at thirteen or fourteen years. He had on his back a load of ore which I estimated at 40 lbs.—and that at an altitude at which the barometer stood at only 458 mm., or about 18 inches. Shortly a more mature boy appeared—perhaps seventeen or eighteen years of age—his load was about 100 lbs. To understand these feats, it must be remembered that exercise may be of two kinds, spasmodic or continuous. In the case of continuous exercise, such as that of long-distance running, the subject must maintain an approximate equilibrium between the oxygen which he uses and that which he absorbs. His oxygen account must, so to speak, balance approximately at any given time. In the case of spasmodic exercise it is otherwise. If the subject is prepared for the exercise to cease after a very short time, he may expend oxygen at a greater rate than he takes it in, and thus overdraw his oxygen account. A limit is, however, set to the overdraft, and when that limit is reached he must rest till his oxygen account has righted itself. This formed the subject of a most interesting investigation carried out by Dr. Lupton recently in the laboratory of Prof. A. V. Hill. The porters in the old Spanish mine raise their loads by a series of spasmodic efforts, each of which is followed by a rest of considerable length accompanied by great respiratory distress.

Of the means by which the body acclimatises itself to oxygen want, real or alleged, we investigated the following:

1. *Secretion of oxygen by the pulmonary epithelium.* Numerous direct estimations were made of the oxygen pressure in the arterial blood, and in the alveolar air. The two usually came out within two or three millimetres of one another, which is approximately the experimental error of the method. Such a coincidence can only mean that the oxygen passes into the blood by a process of diffusion through the very attenuated partition of epithelium which separates the air from the blood in the lung. Thus the view that the lung could enable the body gradually to overcome the effects of altitude by creating a sort of forced draught

[1] I am indebted for this quotation and much else to Mr. Murdock, manager of the coal mine at Quishuarcancha.

and maintaining the oxygen pressure in the blood at its sea-level value is unfounded.

However, the blood as it leaves the lung must contain appreciably less oxygen than its hæmoglobin would normally absorb. It is, to use the American phrase, *un*saturated to a considerable degree. Such blood, of course, would lack the bright scarlet colour of true arterial blood. The actual colour of the blood as withdrawn from the radial artery entirely bore out this view; as it flowed into the syringe it was of a dull red colour often verging on chocolate, and in the case of the natives was 82-86 per cent. saturated with oxygen, instead of 95-96 per cent. as at the sea level.

Curves giving the relation between the percentage saturation of the blood and the partial pressure of oxygen in lungs at Lima and Cerro de Pasca for different members of the party are shown in Fig. 1, from which

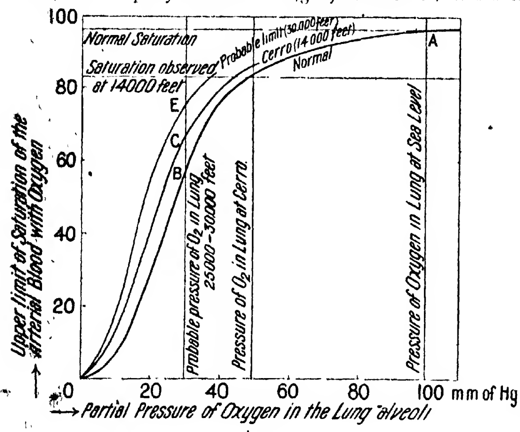

FIG. 1.

it is apparent that at high altitudes the partial pressure required to secure a percentage saturation sufficient for life decreases considerably.

The establishment of the fact that life can be supported with some degree of efficiency with the blood in this condition is of great importance, because in recent years there has been a tendency to assume that a small degree of unsaturation of the arterial blood must of necessity produce very grave results. Fig. 1 shows that there is some adjustment of the blood to the new conditions. At Cerro the unsaturation of the blood was written on the faces of the inhabitants. Any one who had any colour in his face was appreciably cyanosed.

2. *Increased pulmonary ventilation* has been shown by all recent observers to be of great importance as a factor in adaptation to high altitudes. In our case, had our respiration been the same in rate and depth at Cerro as it was at Lima we would have had about 40 pressure mm. of carbonic acid and 35 mm. pressure of oxygen in the air of our lungs. In fact, owing to increased respiratory effort, we reduced the carbonic acid to about 25 mm. and raised the oxygen to about 52 mm. The importance of these facts is enhanced by the certainty that it is the partial pressure of oxygen in the alveolar air which regulates the degree of saturation of the blood.

While the increased ventilation of the lung had been demonstrated by previous observers, the mechanism which was responsible for it had been much in dispute. This we investigated. The mechanism of hypernœa, *at rest* seems to be that first suggested by Haldane, namely, that the want of oxygen heightens the activity of the respiratory centre, resulting in a mild degree of forced respiration—so mild as not to be apparent to the subject, yet sufficient to reduce the carbon dioxide content of his blood. Incidentally, this process acting alone would make the blood more alkaline. The measurements of hydrogen ion concentration in the blood of persons at rest bore out this view; either the blood was more alkaline than at sea level, or it was of approximately the same reaction.

The effect of exercise on the blood has been more fully investigated, though for the most part by indirect methods. Our results support those already obtained, namely, that a given increment in the hydrogen ion concentration of the blood is produced by less exercise at high altitudes than at the sea level. Thus the dyspnœa of exercise is the cumulative effect of two factors—an increased response of the respiratory centre to a given stimulus, and an increase in the stimulus evoking the response

3. I have already alluded to the size of the Cholos chest With it appears to be associated an interesting modification of its configuration Fig. 2 shows two X-ray photos of the left sides of two chests photographed from behind. Both pictures were made at Cerro de Pasco. That on the right is my own, and is fairly typical of our party; that on the left is a typical Cholo chest. There is a marked difference in the angle at which the ribs are carried; my own slope down from the vertebral column at a quite considerable angle, while those of the native are much more horizontal. It seems highly probable that this horizontal carriage of the ribs indicates a compensatory effort designed to increase the facility with which the blood obtains oxygen, for it is acquired at sea level by persons suffering from emphysema and other complaints in which there is shortness of breath. Several of the mining engineers, of whose chests we took radiograms, showed a similar tendency. At this point another peculiar physical conformation may be mentioned, namely, clubbing of the fingers, which, when found at sea level, is frequently associated with some trouble which prevents sufficient oxygen from reaching the extremities. Though they are not the rule, clubbed fingers are by no means unusual at Cerro de Pasco in persons without any circulatory or respiratory lesion.

4. An increase in the number of red blood corpuscles in each cubic mm. of blood has long been known to occur at high altitudes. Systematic researches carried out principally under the direction of Dr. Haldane have shown that the increase in the number of red blood corpuscles is associated with an increase in the quantity of hæmoglobin present. These two observa-

tions we have verified, and to them have added a third, namely, that the chemical conditions under which the hæmoglobin is held in the red blood corpuscle confer on it the peculiarly useful property of acquiring more oxygen when exposed to rare atmospheres than is the case with normal blood.

5. We sought in vain for any such form of acclimatisation as might be afforded by the driving of an increased volume of blood round the body in unit time. A rather natural supposition would be that, if the hæmoglobin of each cubic centimetre of blood were deficient in oxygen, the tissues might be fed with sufficient oxygen by the simple process of giving them more blood; but this is not so. It is true the heart quickened with exercise, but the quickening seems to have been rather a signal of distress than a compensatory mechanism.

Three principal forms of compensation have been described: they are increased total ventilation, increased expansion of the chest, increased hæmoglobin, and increased affinity of the blood for oxygen; their relative importance is a matter for future research. Jointly or severally they may mitigate the effects of oxygen want, but they cannot entirely abolish them; at some altitude the human frame must always succumb. We were naturally somewhat interested in the question of whether we could foretell which of our own party would succumb most quickly, and various members of the party worked out systems of prophecy which differed not only in character but in the prophetic order in which the various individuals would prove susceptible to altitude. One of these proved quite successful. It was based on the determination of Bohr's diffusion constant (the ratio of the quantity of oxygen absorbed per minute to the average difference of pressure between the oxygen in the alveolar spaces and alveolar capillaries) for the lung, and was suggested by Prof. Krogh. The members of the expedition could be divided into two distinct groups—those who had a constant for oxygen of more than 40 and those who had a constant less than that figure. One group with the higher diffusion constant suffered from obvious symptoms of mountain sickness, while the other did not. It is true that of the four who suffered the salient feature was different in each case: in one it was faintness, in another vomiting, in a third high temperature and intense headache, and in the fourth deafness and indistinct vision. Only further research can show whether the coincidence was fortuitous, or whether any causal relation exists between the diffusion constant and the tendency to "soroche." The hint, however, seemed to be worth taking, and in consequence an arrangement has been come to by which persons intending to go to the mining districts in the Andes are being tested in the Rockefeller Institute in New York.

I must also make some allusion to the goodwill which was extended to us by every one with whom we came in contact in Peru, from the President down to the humblest employee of the Cerro de Pasco Copper Corporation. Of the manager and the officials of this company we can only say that their kindness in placing themselves and their resources at our disposal was one of the most potent factors in enabling us to achieve such scientific results as we obtained. No less can be said of the officials of the Pacific Steam Navigation Company.

The problem of Everest from the point of view of physiology, upon which our work in the Andes throws some light, may be stated thus:

Every cubic centimetre of arterial blood which leaves the lung must contain a certain quantity of oxygen,

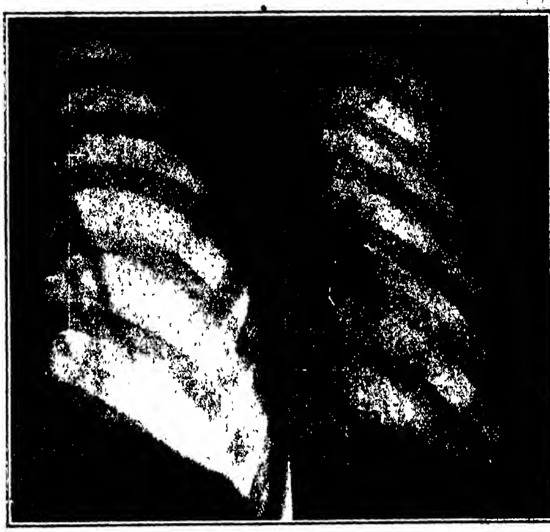

FIG. 2.

expressed as a percentage of the maximum which the blood can hold, if life is to be maintained at a level consistent with any degree of efficiency. It is not known what this quantity of oxygen may be. The following considerations, however, give some clue to it:

(a) Let the maximum quantity of oxygen (shown on the ordinate of the graph in Fig. 1) which the blood can hold be called 100.

(b) There is a certain relation in the blood for normal persons between the amount of oxygen it can hold and the pressure of oxygen to which it is exposed; that relation is shown in the graph labelled "normal." (The partial pressure of oxygen forms the abscissa.) At the sea level the oxygen pressure in the lung is about 100 mm. and the quantity of oxygen in the blood 96 per cent. of the possible load. (See the point A on the graph.)

(c) Until recently it was supposed that the curve did not alter, and therefore the graph labelled "normal" stood for all altitudes.

(*d*) Also the most competent authorities regarded an oxygen load of about 90 per cent. of the possible maximum as *being required for the conduct of life*—apart from short exposures.

(*e*) The probable partial pressure of oxygen in the lungs at 25,000-30,000 feet is calculated by a process of exterpolation to be about 30 mm. Combining *c*, *d*, and *e* above, the quantity of oxygen in the arterial blood on Everest would be 58 per cent. of the maximum—far below that necessary.

(*f*) The recent expedition to Cerro de Pasco has brought out two new points:

(1) That natives lead a reasonably normal existence with blood charged only up to 82 per cent. of the possible, and Europeans with 85 per cent. of the possible, load of oxygen.

(2) *That the graph changes in position, and for* natives and Anglo-Saxons approximates to that labelled Cerro (14,000).

(*g*) On this graph a partial pressure of 70 mm. of oxygen in the lung might saturate the blood up to 67 per cent. (*c*).

(*h*) It is scarcely likely that the curve moves further than that marked "Probable limit (30,000 ft.)." On that curve, however, the blood would be charged up to 76 per cent.—a figure within a reasonable distance of what has actually been observed in the Andes.

Obituary.

H.S.H. Prince Albert of Monaco.

NOT infrequently in the past have princes and nobles been munificent patrons of science and played a useful part in promoting the advancement of knowledge—would that we had more such at the present day—but it must be rare indeed for a reigning prince to attain recognition and distinction as a practical, working, man of science. The late Prince of Monaco, whose death took place recently, was both. He has given to France and the world of science at least three research institutions of first-rate importance, and throughout many years of his life, during the last half-century (since, in January 1873, on one of his early expeditions he met the *Challenger* at Lisbon), he has himself planned and carried out many notable investigations in both physical and biological oceanography.

His Serene Highness Prince Albert Honoré Charles, a descendant of the ancient House of Grimaldi, was born in 1848, and succeeded his father, Prince Charles III., as ruler of the principality of Monaco in 1889. In his early youth Prince Albert served as lieutenant in the Spanish Navy, and since then has shown a life-long devotion to the sea and a rare enthusiasm for its scientific exploration. Probably the most characteristic representation of the Prince is the statue in the entrance hall of the Museum of Oceanography at Monaco showing him in plain sailor's uniform standing at the rail on the bridge of his yacht. He must have spent a large portion of his life, and much of the ample funds at his disposal, in the many expeditions which he conducted in the successively larger and more perfectly equipped yachts *Hirondelle* (a 200-ton schooner) and the first and second *Princesse Alice*—the last a magnificent ocean-going steamer of 1420 tons, built by Lairds' on the Mersey in 1898, and fitted with all necessary machinery and apparatus for every form of modern oceanographic research, and for the capture of whales. By means of these vessels the "Gulf Stream" in its various parts, and its effect on the coast of France, the Azores, the seas around Spitsbergen, the Mediterranean, and much of the Atlantic from the equator to within the Arctic Circle, were systematically investigated in both their physical and their biological characters. Among his companions and assistants on these expeditions have been Baron Jules de Guerne, Dr. Jules Richard, and occasionally our own countrymen Mr. J. Y. Buchanan and Dr. W. S. Bruce; and the results of more than thirty annual cruises have been made known to science first by the Prince's preliminary reports in the *Comptes rendus*, and later, in full detail, in those beautifully illustrated, sumptuous memoirs in the series entitled "Résultats des Campagnes Scientifiques accomplies sur son Yacht par Albert Ier Prince Souverain de Monaco," dating from 1889, and the later series of the Bulletins and the "Annales de l'Institut Océanographique."

It is chiefly in connexion with the devising of apparatus for deep-sea research, and with the introduction of new methods of investigation, that the Prince's personal influence was felt on his expeditions. Among other new appliances which have yielded notable results may be mentioned his huge baited traps (the "Nasse"), his various types of trawls and nets for use in different zones of water, and his use of submarine electric lights to attract free-swimming animals with power of vision, such as fishes and Crustacea. There can be no doubt that his practical knowledge as an experienced sailor and as a mechanical engineer has added greatly to the efficiency and success of all his work on the yachts. His chief assistant, Dr. Jules Richard, who has charge of the museum and laboratories at Monaco, gave full descriptions and useful illustrations of many of these appliances for oceanographical investigation in a special volume of the Bulletin series that was published about 1900.

All the Prince's successive voyages have been very fruitful of scientific results, and biology owes its knowledge of many deep-sea Atlantic animals to the special memoirs issued from the Monaco Press; but none of these have been more remarkable, novel, and almost sensational, than the results of the Prince's whale-fishing expeditions, when he obtained the more or less perfect remains of various new, and in some cases gigantic, cuttlefishes (such as Lepidoteuthis and Cucioteuthis) from the stomachs of captured sperm whales. Some account of these discoveries and exploits, and of Homeric combats when, for example, three huge killer-whales attacked one of the boats and tried to crush it between their bodies, and again when a large Cachalot died under the keel of the yacht which

it had charged as an enemy, are given in one of the recently published volumes of "Accounts Rendered" by Mr. J. Y. Buchanan, who was a companion of the Prince on several of his expeditions.

There is another oceanographic investigation which will always be connected with the Prince of Monaco's name, and that is his distribution, commenced so far back as 1885, of floating or drift bottles over wide areas of the Atlantic, starting from the Azores as a centre, in order to determine the set of the currents. The knowledge acquired from such experiments extending over many years enabled the Prince to write what is probably the latest of his own personal contributions to science, a paper and map communicated to the French Academy, in 1919, on the future of the floating mines which, having gone adrift as the result of operations in the recent war, may be a danger to navigation in certain parts of the Atlantic for some years to come. He showed how mines from the European coasts will gradually be drawn into the various currents associated with the "Gulf Stream," and how some will, in all probability, continue to circulate in the great whirlpool of the Sargasso Sea, while others will eventually find their way to the Norwegian fjords and the Arctic Ocean and be destroyed ultimately in their encounter with the ice.

The inauguration of the Musée Océanographique, towards the end of March 1910, brought together at Monaco such an international gathering of men of science interested in the exploration of the sea as had never been seen before. Official representatives of many countries, delegates from the great Academies of the world, and others invited personally by the Prince, were united in celebrating the progress of oceanography and in launching an institution unique in character and of first-rate importance for science. This great museum with its laboratories and other workrooms rises sheer from the Mediterranean on the southern side of the rock of Monaco, the lower three stories facing towards the sea being below the level of the old town and palace, and the main entrance to the museum from the streets, being half-way up the building. From the seaward side the appearance is especially striking, the masonry appearing to be almost a part of the rock and to grow up in a series of arches from the ledges of the cliff itself. This, the first Museum of Oceanography, demonstrates the methods of investigation and the results obtained. It contains the extensive collections made on the Prince's expeditions, and also shows the various types of dredges, trawls, tow-nets, deep-sea thermometers and water-bottles, current-meters, and other apparatus used by the different nations in their explorations of the ocean.

The museum at Monaco is, however, only one part of the foundation which the Prince has provided for the study of the sea. With the object of arousing interest in scientific marine studies in France, he instituted a series of lectures at the Sorbonne in 1903, and in 1906 he gave permanence to these by means of an endowment, and presented to the French nation a building specially devoted to university instruction in oceanography. In connexion with this "Institut Océanographique" at Paris three professorships have been established—one of physical oceanography, one of biological oceanography, and the third of the physiology of marine life. As was said of him at one of the inaugurations, "By his researches the Prince of Monaco has won for himself a distinguished place in the ranks of men of science, and by enshrining the results in the monumental buildings at Monaco and Paris he has invested his labours with permanent value for all time."

The third great scientific benefaction of the Prince is the Institut de Paléontologie Humaine at Paris, where again, as at Monaco, there is a museum and a laboratory with professors devoted entirely to the investigation and demonstration of one special subject—the early history of man. The Prince's personal interest in prehistoric archæology has been shown for many years by the explorations he has conducted or promoted at the Grimaldi caves near Monaco and at other caverns and important sites in France and Spain, with Prof. Boule, the Abbé Breuil, and others—and the results, as in the case of the oceanographic investigations, have been published at his expense in princely style. It has been reported in the daily press, since his death, that he has bequeathed a million francs, as further endowment, to each of these three research institutions. He has certainly put to a noble purpose for the advancement of science the ample funds which have come to him under the conditions of the concession granted many years ago to the proprietors of the Casino at Monte Carlo. It is well known that the Prince has expressed publicly his strong disapproval of the pigeon-shooting competitions at Monte Carlo; but considers that as he is not an autocrat, under the terms of the concession, he has no power to interfere with vested interests at the Casino except by the support his name and influence can give to public opinion.

None of those who were present at Monaco as the Prince's guests, during the four days of conferences and celebrations at the inauguration of the Musée Océanographique, will be likely to forget his gracious hospitality, his gravely courteous manner, his evident interest in all the scientific questions raised, and his keen desire to secure co-operation between the different nations in the further exploration of the oceans. In recent years, since the war, he has played a prominent and most helpful part in such international co-operation. He was appointed president of the "Commission internationale pour l'Exploration scientifique de la Mer Méditerranée" at the meeting in Madrid in 1919, and at the recent international conference in Rome he was chosen as president of both the physical and biological sections of oceanography. In all such meetings and in the subsequent work he was no mere figurehead, but took a prominent part in the proceedings. His death, in Paris, on June 26, will leave a great gap in many important organisations, and be felt as a real loss by all interested in the promotion of the science of the sea. He was a natural centre in organisation and a leader in work. In his independent position he stood apart from all international rivalries and showed only a single-minded devotion to the pursuit of truth. As he once said of himself, modestly and truthfully, in an address on his work at sea, in July 1891, to the Royal Society of Edinburgh, "I undertook the mission that lay before me because I was at once

a sailor and devoted to science." And that seems to express his attitude throughout all his work.

W. A. HERDMAN.

THE death is announced in the *Chemiker Zeitung* of June 24 of Prof. W. Hallwachs, of the Technische Hochschule, Dresden, on June 20. Prof. Hallwachs, who was sixty-three years of age, was known for his researches on electricity, particularly on the photo-electric effect. The same journal also records the death of Prof. Otto Lehmann, on June 20, at the age of sixty-seven. Prof. Lehmann, who has occupied the chair of physics at the Technische Hochschule at Karlsruhe since 1889, was best known for his work on liquid crystals. His first paper on this subject was published in 1890, and his further researches were embodied in two monographs published later. In addition, he carried out work of importance in connexion with discharge and cathode-ray phenomena.

Current Topics and Events.

COL. E. M. JACK has been appointed Director-General of the Ordnance Survey in succession to Sir Charles Close, who is retiring in August.

THE *Chemiker Zeitung* announces that Prof. H. Kamerlingh Onnes, director of the Physical Institute of the University of Leyden, Dr. P. Zeeman, professor of physics at the University of Amsterdam; and Dr. N. Bohr, professor of theoretical physics at the University of Copenhagen, have been elected corresponding members in the Physical-Mathematical Class of the Prussian Academy of Sciences, Berlin.

THE Charles P. Daly medal of the American Geographical Society has been presented on behalf of the society by the American Ambassador to Sir Francis Younghusband. The medal, which was instituted under the will of the late Charles P. Daly, sometime president of the American Geographical Society, is awarded for valuable or distinguished geographical services or labours, and that presented to Sir Francis Younghusband bears the inscription, "For explorations in Northern India and Tibet and for geographical publications on Asiatic and African borders of the Empire."

SOME appointments have recently been made on the scientific staff of the Field Museum of Natural History, Chicago. Mr. R. Linton has been attached to the department of anthropology as assistant curator of North American ethnology. Mr. Linton has carried out extensive investigations, principally archæological, in the eastern, central, and south-western United States, as well as in Central America and Polynesia. Recently he has returned from an expedition to the Marquesas Islands for ethnological and archæological researches, undertaken under the auspices of the Bishop Museum of Honolulu, Hawaii. A new division of taxonomy has been created in the department of botany, and Mr. J. F. Macbride, now in Peru at the head of a botanical expedition for the Field Museum, has been designated as assistant curator. In the department of zoology, Dr. C. E. Hellmayr, well known for his extensive work on Neotropical birds, has been appointed associate curator of birds. Dr. Hellmayr was formerly connected with the Rothschild Museum at Tring, and more recently has been with the Museum of the University of Munich. Mr. Heller, a former associate of Theodore Roosevelt, and Mr. J. T. Zimmer have been appointed assistant curator of mammals and assistant curator of birds respectively; they are at present engaged in field work in Central Peru. Mr. Karl P. Schmidt, formerly with the American Museum of Natural History, New York, has been appointed as assistant curator of reptiles and batrachians.

JUNIOR Beit Memorial Fellowships for medical research of the annual value of 350*l.*, and tenable for three years, have been awarded by the trustees to the following, the subject and place of research being given after each: Mr. E. B. Verney: The physiology and pathology of urinary secretion, at the Institute of Physiology, University College, London; Prof. F. Cook: A study of the neuromuscular apparatus of the uterus, at Guy's Hospital; Dr. J. L. Rosedale. The chemistry of normal and pathological tissue with special reference to the protein and nuclein constituents, at St. Thomas's Hospital Medical School, London; Mr. R. Hilton: The study of the blood gases in various stages of pulmonary collapse produced by artificial pneumothorax; the condition of the circulation in the collapsed lung, at the Laennec Hospital, Paris, and at St. Bartholomew's Hospital; Mr. A. St. G. J. M'C. Huggett. The investigation of the function of the placenta in relation to the passage of gases and other substances from the mother to the fœtus and the cause of fœtal apnœa, at the Sherrington School of Physiology, St. Thomas's Hospital, and at the Brown Animal Institution at Vauxhall; and Mr. V. D. Allison: The investigation of the nature and properties of a hitherto undescribed substance which has a strong bacteriocidal, bacteriolytic and bacterio-inhibitory action—named lysozyme, at the Institute of Pathology and Research, St. Mary's Hospital. Fourth year Fellowships of the annual value of 400*l.* have been awarded to Dr. D. Keilin: The life-histories of protozoa pathogenic to insects; the life-history, anatomy and physiology of insects, at the Molteno Institute for Research in Parasitology, Cambridge; and Mr. I. de B. Daly: Auriculo-ventricular block, at the Institute of Physiology, University College, London. The trustees of the Beit Scientific Research Fellowships have re-elected Mr. H. L. Riley and Mr. W. A. P. Challenor to fellowships for the year commencing September 1922, and elected Mr. H. W. Buston to a fellowship for the same period. All the fellows are required to carry out their research at the Imperial College of Science and Technology. Mr. Riley will continue his research on "The

Atomic Weight of Silver and the Dielectric Constants of Dry Gases" in the chemistry department, and Mr. Challenor will continue his work on "Ring Formation in the Aromatic and Aliphatic Series of Organic Chemistry" in the chemistry department, both under the direction of Prof. H. B. Baker. Mr. Buston will carry out investigations on "Nitrogenous Metabolism in Plants" in the biochemistry department under the supervision of Prof. J. B. Farmer.

THE final attempt, at least for this year, to reach the summit of Mount Everest was made on June 7. The party, according to General Bruce's despatch to the *Times*, consisted of Messrs. Mallory, Somervell, Finch, Wakefield and Crawford, with native coolies. From the outset bad weather was experienced. Captain Finch, feeling the result of his great exertions during the previous climb, had to give up and return. On the North Col the rest of the party were caught in an avalanche; Messrs. Mallory, Somervell and Crawford and one porter were able to extricate themselves unhurt, but the second party consisting of porters were overwhelmed. Three of them were rescued, but seven lost their lives. The attempt to gain the summit was then abandoned. General Bruce writes in terms of great praise of the loyalty and devotion of the native porters, whose loss the expedition felt keenly. Most of the Europeans with the expedition appear to be suffering from exposure at high altitudes; there are several cases of frostbite. It is not yet decided if a new attempt on Mount Everest is to be made next season. Several members of the expedition, including Colonel Strutt, Dr. Longstaff and Captain Finch, have already reached England.

FOR some time past the practicability of measuring the depth of the ocean by means of sound waves reflected from the bottom has been discussed. A short explosive signal is made at the ship's hull and the time of this, and the echo from the bottom, are recorded. Apparently corrections are made for temperature effects on the velocity of transmission of the signal. Obviously the measurements can be repeated very quickly, or they may even be carried out automatically. It was announced in New York, on July 6, that extended trials had been made by Dr. Hayes, on board one of the U.S.A. destroyers, with much success. The outline of the sea bottom on a traverse between Rhode Island and Gibraltar is said to have been charted and minute records between Josephine and Tysburg Banks have been obtained. The bottom here is an extensive plain, bordered by mountains and tablelands rising to a height of 4000 feet above the plain, and containing several unrecorded deeps. Doubtless the apparent uniformity of level over vast areas of ocean bottom is to be explained partly by the paucity of deep soundings: this applies particularly to much of the Pacific Ocean. Should the new method prove trustworthy on critical investigation it will be possible to study the minor differences of depth with ease.

A MEMORANDUM regarding the probable amount of monsoon rainfall in 1922 was submitted to the Government of India in the early part of June by Dr. G. T. Walker, Director-General of Observatories. As frequently happens there are said to have been temporary advances of the monsoon in May, and in early June the rains began much earlier than usual in upper India, but the advance did not persist. The monsoon rainfall is affected by previous conditions over various parts of the earth, and a summary is given of the recent data which appear to be of importance. Among the factors stated as available are: a slight excess of snow in the mountain region of north-west India, a deficiency of rainfall over Java during the period of October to February, an excess of rain in Ceylon during May, and an excess of pressure at Mauritius in the same month. The data of Java, the Azores, and South America are decidedly favourable, of Iceland and the Cape scarcely appreciable, and of the east African coast decidedly unfavourable. The resulting indication shows that the Peninsula rainfall will be in excess, and for north-west India the rain is likely to be slightly deficient but not far from the normal. The establishment of the Arabian Sea monsoon will probably be delayed. For Upper Burma, north-east India, Mysore, and Malabar the indications are said to be conflicting and a useful forecast cannot be made.

THE Empire Forestry Association, which held its inaugural meeting in November last, was founded with the object of federating all the various societies interested in forestry throughout the Dominions overseas and India, as well as in the home countries. One of the functions of the Association is to disseminate information by means of a journal, *Empire Forestry*, the first number of which appeared in March. This contains about a dozen articles, the most important being a statement by Mr. R. L. Robinson, Forestry Commissioner, concerning forestry practice and available timber supplies throughout the Empire, based on the latest official information and statistics. Canada heads the list, as regards forest area, with 932,420 square miles of forest lands, of which, however, only 390,630 square miles are considered to be merchantable, the remainder being unprofitable or inaccessible. British India is second, with 126,310 square miles of merchantable forests; Nigeria is next, with 50,400 square miles; while Australia has 37,840 square miles. It is fortunate that 75 per cent. of the forest area of the Empire still belongs to the State. There is time yet to preserve the forests from ruthless destruction, by wise legislation aiming at effective regulations as regards felling, natural regeneration, and protection from fire. A useful feature in this number of *Empire Forestry* is a list of books, reports, and other publications on forestry and timbers, issued in 1920 and 1921.

REPORTS on lac, turpentine, and rosin have been issued by the Imperial Institute (London: J. Murray; 5s. net). Shellac is a characteristic Indian product, and indeed 94 per cent. of the world's supply comes from India and Burma. It is a resinous exudation produced by the lac insect, *Coccus lacca*, on various trees. In spite of the practical monopoly enjoyed,

the state of the industry in India is not satisfactory, and recommendations for improvement in the manufacture are given. The other reports deal with Indian turpentine and rosin. These have been produced on a small scale for some time past in the United Provinces and the Punjab, only one species of pine, *Pinus longifolia*, being tapped commercially. The turpentine of this tree is unfortunately inferior to that produced in the American and French forests. It appears that a much better turpentine could be obtained from *Pinus excelsa*, another species widely spread in the Himalayas, but the yield is small. *Pinus khasya* might also be tapped in Assam and Burma. The industry is at present merely in the experimental stage; but it is predicted that, with energetic business methods, the total annual yield, which is now trifling, might be increased in ten years to 120,000 cwts. of turpentine and 430,000 cwts. of rosin.

A CASE in which two cuckoos were apparently reared together in the same nest by a cock blackbird is recorded by Miss E. R. Saunders, Newnham College, Cambridge. A blackbird's nest containing four eggs on which the cock bird was sitting was found and observed. The fact that a dead hen blackbird was found close by afterwards may account for the continued presence of the cock bird on the nest. When the eggs hatched, two of the nestlings were blackbirds, the bodies of which were found on the ground, while in the nest was a young cuckoo. Another young cuckoo was perched on a stake within a hand's breadth of the nest. Cuckoos frequent a belt of trees nearby, and it seems in this case that two eggs were deposited in the one nest.

IN regard to the correspondence in NATURE of March 9 and June 3, under the title "A Rainbow Peculiarity," on the enhanced brightness of the sky within the primary bow, Mr. L. C. W. Bonacina writes to point out that the fact is splendidly illustrated, and duly commented upon, by Mr. G. A. Clarke in his book on "Clouds" published in 1920 (Plate 35*b*).

A NEW classified list of second-hand scientific instruments (No. 75) has been issued by Mr. C. Baker, 244 High Holborn, W.C.1. As is customary in these well-known catalogues, the instruments are arranged in groups and there are long sections dealing with microscopes, many by first-class makers, and telescopes and accessories. Among the electrical apparatus we notice a Marconi receiving instrument, and there is also a quantity of apparatus suitable for other departments of physics as well as surveying and drawing instruments. Most of the apparatus can be inspected at Mr. Baker's premises. A novel feature is the offer for hire, at very moderate charges, of field- and opera-glasses of various types.

Our Astronomical Column.

SKJELLERUP'S COMET.—The identity of this comet with 1902 II (Grigg) is now very highly probable. Mr. G. Merton finds, with the aid of recent Greenwich photographs, that the period of Skjellerup is close to 5·13 years, the other elements being nearly the same as those recently given in this column. Further, the following new orbit has been deduced for 1902 II., which represents the observed places within a few minutes of arc, an amount well within their probable error:

$$T = 1902,\ \text{July } 2{\cdot}52 \text{ G.M.T.}$$
$$\left.\begin{array}{l}\omega = 346°\ 41'\\ \Omega = 222°\ 40'\\ i = 9°\ 4'\end{array}\right\}1902{\cdot}0$$
$$\phi = 48°\ 12'$$
$$\log a = 0{\cdot}4662$$
$$\text{Period} = 5{\cdot}004 \text{ years.}$$

The period was assumed, since the observations are not nearly precise enough to determine it. The other elements are fairly near those of Skjellerup. The differences are explicable by the fact that there was a very near approach to Jupiter at the beginning of 1905. By the above elements the comet was then in Longitude 29½°, N. Lat. 2°, log r 0·7081; Jupiter was in Longitude 32°, S. Lat. 1°, log r 0·6959.

THE PARIS ASTROGRAPHIC CATALOGUE.—M. Jules Baillaud notes in *Comptes rendus* for July 3 that this Catalogue, which extends from North Declination 18° to 24°, is approaching completion, and it is already possible to give data about the number of stars per plate in the different parts of the zone. He does this in two ways: (1) the uncorrected numbers, (2) the numbers after allowance has been made for variations due to imperfectly clear sky, less sensitive plates, etc. These have been estimated by comparing the overlapping portions of adjacent plates. Both sets of numbers are shown graphically. There are two steep peaks in the curve at 6^h and 21^h R.A., where the zone intersects the galaxy. The curve indicates 1100 stars per region of 6° × 6°·6 at 6^h R.A., and 1200 stars at 21^h R.A.

The minima are at 3^h and 14^h R.A., where the star numbers are 150 and 70 respectively per 6° × 6°·6. There is thus a 14-fold range in star-density. It will be noted that the minima do not fall symmetrically between the maxima.

OBSERVATIONS OF MARS AT SÉTIF, ALGERIA.—M. R. Jarry-Desloges has sent a report to the Paris Academy of Sciences of observations which he and M. G. Fournier have made this year (*Comptes rendus*, July 3). They have used two refractors, apertures 37 cm. and 26 cm.; it is noted that the smaller has practically no secondary spectrum, although there are only two lenses in the objective. While this is advantageous in most cases, M. Fournier finds that for the purpose of detecting slight colour-differences on the planets the former is preferable.

Some of the dusky regions in the southern hemisphere of Mars were seen to be covered with a misty veil, and M. Desloges notes that this was also seen in 1909 when the season on Mars was the same. He also directs attention to the difficulty of tracing the southern boundaries of these dusky regions: a similar difficulty was experienced in 1907, but in intermediate years these boundaries have been well defined. The misty veil is stated to be lifting, so that by June the boundaries could be traced. As a change that is probably not seasonal he adduces the present great development of the system Lacus Moeris, Nepenthes, Thoth, to the left of Syrtis Major. These features were not seen in 1907.

Lacus Phœnicis is large at present, and Lacus Solis is girdled by a system of dark streaks. Fons Juventæ has also been seen.

Research Items.

FOLKLORE AMONG THE ALGERIAN TRIBES.—In the June issue of *Folk-lore* (vol. xxxiii. No. 2) Mr. M. W. Hilton-Simpson publishes the result of a series of excursions among the hill and desert tribes of Algeria. In this hitherto practically unknown field he has found many curious usages. Among others, at a marriage firearms are discharged to scare the Jinn who are on the watch to possess the bride. On her arrival at her husband's house she is lifted into the house by a man, and as she reaches the door a female member of her family presents her with an egg, which she breaks on the lintel as she passes under it. This last usage is sometimes modified by the bride smearing the door-lintel with butter, the series of charms being probably fertility magic.

RELIGIOUS CEREMONIAL OF THE PARSIS.—An interesting collection of articles used in religious ceremonies by the Parsis of Bombay and preserved in the United States Museum is described by Mr. I. M. Casanowicz, the assistant curator, in Proceedings of the United States National Museum (vol. lxi. Art. 2), with a useful account of the origin and ritual of these people. The finest object is a brass nickel-plated fire-iron, with a ladle and tongs, used in making the sacred fire, and a similar tray on which offerings of fruit, flowers, milk, water, wine, or sherbet are made in remembrance of the souls of the departed, or with the object of invoking the help of protecting spirits.

FAR EASTERN ARCHÆOLOGY.—The July issue of the *Antiquaries' Journal* (vol. ii. No. 3) is devoted to the presidential address by Sir Hercules Read, who took as his subject the work of Sir Aurel Stein carried on for twenty years in exploring Eastern Turkestan. "The masterpieces of the earlier dynasties of China stand unchallenged in our museums and in private possession. Their value and interest are enhanced beyond words when we have in addition such a collection as that brought home by Sir Aurel Stein. By singular good fortune he has retrieved just the very objects that the earth can never yield to us. Pictures, embroideries, manuscripts, such as constitute his hoard, even if they had been buried in the graves, would have been destroyed by damp in much less than a thousand years. His finds in the bone-dry caves of the Thousand Buddhas form the necessary complement of what excavation has yielded from China itself, with the result that we have in England what is probably a unique mass of material for the study of Chinese archæology, religion, and art during the three centuries preceding the Norman Conquest."

THE PILTDOWN SKULL.—Since the discovery of fragments of a human cranium and jawbone at Piltdown in Sussex in 1912 a fierce controversy has raged over these interesting remains. The recent contributions to the discussion are reviewed by Mr. E. N. Fallaize in the July issue of *Discovery*. As regards the question of dating, he remarks that the claim of its identification as a specimen of Pliocene man must be held not to be proven. As to the character of the skull, a fresh reconstruction of it has recently been made by Profs. Elliot Smith and Hunter, generally confirmatory of earlier reconstructions of Dr. Smith Woodward and Mr. Pycraft. It is low and broad and of a capacity less than 1300 c.c. It differs, however, in one important respect. The occipital fragment, which determines the shape of the back of the skull, assumes a more vertical position, and produces a form more nearly resembling the anthropoid skull than that of modern man. The result is a skull like no other skull, but its similarity to the Simian skull brings it into complete harmony with the chimpanzee-like jaw. The difficulty of the discrepancy between cranium and jaw has thus been cleared up, while the endocranial cast, as might be expected, takes its place between that of *Pithecanthropus erectus*, the fossil skull from Java, and that of the recently discovered Rhodesian Man.

PALÆOZOIC BRACHIOPODA FROM EASTERN ASIA.—Two parts of a paper, which constitute a portion of the attempt of the Geological Institute in Sendai (Japan) to contribute to the knowledge of the geology of Eastern Asia, are contained in the Science Reports of the Tôhoku Imperial University, Sendai (Second Series: Geology, vol. vi. No. 1). In these, Ichirô Hayasaka discusses the palæozoic Brachiopoda from Japan, Korea, and China. The majority of forms are referred, although occasionally doubtfully, to species well known from the same strata in other parts of the world, but in one case the author has felt justified in establishing a new genus, Athyrisina, for two Middle Devonian species, also new. The seven photo-lithographic plates are good, but sometimes wanting in clarity; more exact illustration would have been especially acceptable in the case of the new genus and its species.

MIMICRY AMONG BIRDS.—Mr. G. T. Harris, Buckerell, East Devon, has sent us a description of a robin attacking a cuckoo. The latter species is frequently harassed by single small birds in this way, or is "mobbed" by a band of them. At first sight this might seem to indicate resentment of the cuckoo's parasitic habits, but it is probably going too far to credit the victimised species with so intelligent an awareness of the position; for although the chosen foster-parents will try to drive off a cuckoo about to lay in their nest, they will subsequently hatch the egg and rear the young parasite in a way which shows that they have indeed no understanding of the trick which is played upon them. A more credible explanation is to be found in the cuckoo's similarity to a hawk, for small birds will "mob" hawks and owls in much the same way when they can get these birds-of-prey at a disadvantage. The cuckoo is a comparatively weak bird, and its mimicry of a hawk is doubtless useful both in regard to its peculiar breeding habits and otherwise, although at times it entails the unwelcome attentions referred to above. This interesting mimicry is probably to be regarded as a definitely evolved adaptation; the alternative explanation of mere coincidence might perhaps be urged if there were not numerous other examples to show that such mimicry is quite possible. There is an Indian cuckoo, for example, which habitually victimises a drongo as a foster-parent and closely resembles that species in outward appearance. Again, there is the striking case of the friar-birds and orioles of the Malay Archipelago; here the weak orioles appear to gain an advantage in the struggle for existence by their close mimicry of the pugnacious friar-birds. Moreover, there are several species of friar-birds on different islands, and for each there is an appropriate oriole. Among insects, too, there are many good examples of the mimicry of one species by another and unrelated form.

EARTHQUAKES IN THE REGION AROUND TOKYO.—Prof. Omori contributes to the second number of the new journal, *Seismological Notes*, an interesting paper on the Tokyo earthquake of December 8, 1921, the strongest experienced in that city since 1894, though resulting in only slight damage to buildings. The shock was notable for its extraordinary duration, having been sensible for three minutes. The position of the epicentre, as determined by the duration of the preliminary tremors at Tokyo, Mito and Choshi, is 58 kms. N. 65° E of Hongo (Tokyo). The actual distance of the focus from the latter place was, however, 65 kms., leading to the conclusion that the depth of the focus was about 29 kms. or 18 miles. Prof. Omori also considers the distribution of Tokyo earthquakes in space and time. Those of the eight years 1914–1921 originated for the most part in four regions, three of them at a mean distance of about 35 miles from Tokyo, the district surrounding the capital being at present immune, and the fourth a submarine zone off the eastern coast of the Main Island. The curve of annual frequency beginning with the year 1876 resembles so closely the curve of mean precipitation at Niigata and Akita (places in the Japan Sea region with an abundant snowfall) as to suggest the probability that the precipitation on the north-west side of the Main Island may be one of the secondary causes that determine the frequency of earthquakes felt in Tokyo.

AURORAL MEASUREMENTS.—In No. 8, vol. ii., *Geofysiske Publikationer* of the Norwegian Geophysical Commission, Prof. Karl Stormer gives further results of his auroral measurements. As a check on the accuracy of his methods, he deals with simultaneous observations taken on March 22, 1920, at Christiania, Kongsberg and Frederikstad. Combining the stations in pairs, he gets three sets of results derived from three differently oriented bases, having lengths of approximately 66, 70, and 80 kilometres. The heights of three selected auroral points are calculated in two different ways. As the accuracy seems much the same for the two methods, it will suffice to give the results of the first. The means of the heights calculated for the three points were 143, 177, and 214 km., and the differences between the highest and lowest of the three estimates from the three bases were respectively 5, 5, and 7 km. A second chapter deals with observations on the height and position of an auroral arc determined from observations with a base of 258.5 km. As seen from the southmost station, near Christiania, the arc was near the horizon. It was overhead at a point situated about 700 km. to the north-west. Besides diagrams in the text there are eight large plates, the first two referring to the cases described above. The others are selected as among the finest auroras which Prof. Stormer has yet photographed. In some cases difficulty may be experienced in deciding which is the top and which is the bottom of the picture. This might with advantage have been stated in words on the plates.

THE NEW MAGNETIC ATOM AND ITS PROPERTIES.—In order to improve his original theory of magnetic induction in ferromagnetic materials, Sir J. A. Ewing published in February his theory that the magnetic element is not the atom itself but something smaller which can rotate within the atom. It may be likened to a wheel with a number of like poles on its rim and the poles of opposite kind at its centre. Around it is a fixed ring provided with magnetic poles, under the action of which the wheel may take up a number of positions of equilibrium. Two months later, Prof. E. T. Whittaker showed that a model of this type, when approached by an electron with kinetic energy exceeding a certain amount U, would take from it an amount U depending on the electronic charge and on the constants of the model, and that if n is the frequency of the oscillations of the model and of the radiation it emits, then $U = hn$ where h is the constant of the quantum theory. More recently Dr. H. S. Allen has pointed out that such a vibrator would not lead to the equipartition law, and Dr. R. A. Houston has shown that for the model to vibrate with the frequency of sodium light its diameter must be $2{\cdot}7 \times 10^{-8}$ cm. and with X-ray frequency $3{\cdot}5 \times 10^{-10}$ cm. which agree well with the known diameter, 2×10^{-8} cm. of the hydrogen atom. The four papers mentioned will be found in the Proceedings of the Royal Society of Edinburgh.

STRUCTURE OF ABRADED GLASS SURFACES.—A series of papers issued from the Research Department of Messrs. Taylor, Taylor and Hobson, Ltd., and published in the current number of the Transactions of the Optical Society, provide a valuable contribution to our knowledge of the physical nature of the processes involved in the workshop operations of cutting and grinding, particularly of hard brittle substances. Detailed photomicrographic studies of the structure of ground glass surfaces and of the flaws produced in glass by various means lead the author, Mr. F. W. Preston, to the conception of a flaw and fissure complex rather than the current view of a hill and hollow structure as characterising a ground surface in brittle materials. His experiments show that in polishing as well as in grinding, the forces of mechanical abrasion are active, although in the former case they tend to be obscured by surface tension effects. During polishing the whole of the flaw complex previously formed is broken away from the roots and a slight molecular rearrangement of the new surface then takes place, as observed by Beilby, who has demonstrated the existence on all polished surfaces of a flowed (surface tension) layer. The enhanced solubility of ground surfaces in hydrofluoric acid, and also the appearance of the structure of polished surfaces as developed by etching, suggest a low value for the thickness of this surface tension layer—in the case of glass some two or three millionths of an inch at the most.

REPEATING PATTERNS AS DECORATIONS.—The Journal of the Royal Society of Arts for June 30 contains an interesting paper by Major P. A. MacMahon on the design of repeating patterns for decorative work. Major MacMahon has recently investigated the modes of dividing flat space into identical figures without gaps or overlapping. Such divisions are familiar to every one in wall paper designs, which are generally formed by cutting up the plane first into identical parallelograms. More complex types of repeating pattern were designed in very early days and some of them still survive in ancient tessellated pavements. The method of classification obtained by Major MacMahon has proved wide enough to place every such design brought to his notice, and he has reasons for thinking that it is exhaustive. He reports that at least 90 per cent. of the few hundreds of categories have apparently never been drawn upon for practical application. The paper is illustrated by a few specimen patterns, some of which are sufficiently remarkable to merit close attention from those engaged in decorative work. An interesting fact, which does not appear to have been generally recognised before, is that a plane can be completely filled with congruent quadrilaterals of any shape.

Leicester Conference of the Museums Association.

THE thirty-third annual conference of the Museums Association, held on July 10-15 at Leicester, under the presidency of Mr. E. E. Lowe, director of the Museum, Art Gallery, and Libraries in that city, was attended by eighty-six members, comprising delegates from most of the leading museums, national and provincial, in the British Isles, as well as from Canada and the United States. The admirably organised hospitality of an influential reception committee rendered the meeting one of the most enjoyable in the history of the Association; and the devoted labours of its experienced president with his helpers, in their endeavours to make up for the regretted absence of the secretary, Dr. W. Tattersall, through illness, led to an unusual smoothness of working. Above all, the papers and discussions were thoroughly practical, and seemed likely to produce valuable results.

The president divided his address into a more popular part, for the benefit of the local dignitaries and other friends who attended the opening meeting, and a more technical part addressed to the members of the Association alone This is an example that might sometimes be followed elsewhere. The first part showed how romance could be extracted from the objects in a museum and used to make more effective contact between the museum and the public The second part suggested a means by which the Association might undertake more constructive work than it had previously been able to accomplish, and by which members other than the officers and council could take a more continuous and active share in the life and labours of the corporate body This was the establishment of sub-committees, similar to those of the British Association, to conduct inquiries during the year and to report through the executive to the annual meeting. The proposal was taken up by the Council and welcomed by the meeting Three such sub-committees were appointed to investigate matters already laid before the conference. Thus Mr. E Rimbault Dibdin's paper on the organisation of picture exhibitions in the provinces led to the appointment of a committee to consider his proposals A second committee, arising out of a demonstration by Mr. E. Howarth, is to report on the cleaning and restoration of pictures The third committee is to investigate and report upon preservative solutions and upon cements for use with various preservatives This committee, as at present constituted, comprises Dr W. E Hoyle (chairman), Dr G Hay Murray, and Dr. J. J Simpson (secretary), and will doubtless welcome assistance from every quarter The last two gentlemen presented to the meeting notes and demonstrations on cements and labelling for spirit specimens

Other practical communications included a demonstration by Sir Sidney Harmer of his researches on the fading of museum specimens, illustrating his important paper published in a recent number of the *Museums Journal* and previously noticed in these columns, a paper and demonstration on taking squeezes of fossils by Dr. F A Bather; and a paper on museum labelling and printing, by Mr A. T. Roberts, head of the Leicester School of Arts and Crafts. Leicester is famous for its printing and lettering, and the labels in the Leicester Museum admirably exemplify the influence of this school, while the exhibitions held there from time to time help the business community to improve the style of advertisement. Mr. Leney, of the Norwich Museum, recounted his success in obtaining money for museum purposes through an organisation known as "Friends of the Museum"; Mr. R W. Brown, of Northampton, made sound suggestions on mutual co-operation between museums and public libraries; Mr. Williamson, of Derby, discussed the classification of Derby porcelain; Prof. Parks, of Toronto, described the constitution of the Royal Ontario Museum, and Mr. R F. Martin reported on the Buffalo meeting of the American Museums Association which he had attended. Mr. J. Bailey urged the appointment of a Royal Commission "to investigate and report upon the work of museums of the United Kingdom in relation to industries and general culture" and his proposals, endorsed by a large meeting, were subsequently adopted by the council

In connexion with the conference there were arranged at the museum an exhibition by the British Institute of Industrial Art, an exhibition of wood-grain panels, executed by Mr A J. Rowley, after designs by well-known artists, and a number of modern paintings lent by artists of international reputation. Bearing more directly on the work of the Association were two rooms filled with exhibits by members and by fifteen business firms, all of which attracted the constant attention of the delegates and other visitors throughout the week But perhaps the most illuminating and inspiring exhibit was the Leicester Museum itself, not so much for the building or the specimens contained in it as for the prevailing sense of life and directing intelligence. The numbers that thronged the galleries on Sunday afternoon and the cordial assistance of the Mayor and many members of the corporation showed how highly the people of Leicester appreciate a museum and a director of whom they may well be proud In doing so they prove how true are the principles for which the Museums Association and notably its retiring president have never ceased to strive

The next conference will meet at Hull in July 1924, under the presidency of Mr Thomas Sheppard.

The Arrangement and Motion of the Sidereal System.

THE above is the title of the late Prof Kapteyn's last paper, which appeared in the *Astrophysical Journal* for May. In an earlier paper he had shown that the surfaces of equal stellar density are approximately ellipsoids of revolution, modified, however, by inflexions near the pole. In the present paper he assumes the exact ellipsoidal form, for convenience of computation, though admittedly not quite in accord with fact. He draws ten ellipsoids, embracing the known portion of the stellar system; the semi-minor axes (towards the galactic pole) range from 118 to 1660 parsecs, while the radii of the circular galactic sections are in each case 5·1 times the polar semi-axes. The logarithms of the star-density in the successive shells fall off from 0·00 in the inner to 8·[illegible] in the outer, the density in the sun's neighbourhood being the unit. For simplicity the sun was taken as central, its most probable distance from the centre is given as 650 parsecs, the latter lying in R.A. 23^h 10^m, N. Decl. 57°; this is not far from Kapteyn's 1893 position, which was R.A. 0^h, N. Decl. 42°. Kapteyn noted that his work would need correction for this eccentric position of the sun, and also for the fact that he combined stars of all spectral types together, though it is known that there are systematic differences in their motions.

The convenience of assuming that the successive shells are ellipsoids is that each shell exerts no attraction on the space within it, and if there are other similar shells outside the outermost one considered,

these will have no effect. Assuming that there are no dark stars or bodies the average masses of the stars are found to fall off from 2·2 near the sun to 1·4 in the outer regions. The mean is 1·6, practically the same as Jackson and Furner found from a study of binary stars. This seems to show that the amount of dark matter in the system is relatively small; we may infer that the duration of the system in the past is not greatly longer than the luminous period of individual stars. The two star-drifts are ascribed to rotational movements of the stars in opposite directions about the galactic polar axis, an idea that was also suggested by Eddington in the Jubilee Number of *Astronomische Nachrichten*.

Kapteyn shows that the supposition explains not only the observed directions of the drifts but also their numerical amounts, namely, 40 km./sec. for the relative velocity of the drifts. It is noted that if the drifts are really due to circular motion the more distant stars should give somewhat different apices from the nearer ones. This will afford a test of the theory.

Some preliminary statistics based on the study of the "Selected Areas" were used in the paper; when these data are fully available it will be possible to give improved values of the star-density in the outer regions. The paper is noteworthy as being one of the earliest attempts to explain dynamically all the star-movements in the system; while avowedly only approximate, it supplies a foundation on which more exact researches may be based.

The Oil Palm in French West Africa.[1]

THE resources of the French possessions in West Africa in oilseeds and nuts are practically inexhaustible, and considerable attention is now being given by the colonial authorities to the possibility of greatly increasing the supplies of these valuable products by scientific research, particularly in the direction of plant-breeding and selection, and the most up-to-date methods of cultivation. In collaboration with the Institut Colonial de Marseille the Governor-General of French West Africa is establishing research stations and experimental plantations in Dahomey and on the Ivory Coast, chiefly for oil-palm study, but work on the cotton plant and ground-nut (arachis) will also be included. It is estimated that, with proper methods, 300,000 tons of palm oil per annum could be obtained from the Ivory Coast alone. Two oil-palm experimental stations have been already planned, and a chemical and botanical staff is being engaged for the work under M. Teissonnier, Director of Agriculture of the Ivory Coast.

The programme of research both at Bingerville and at Dakar will include primarily the improvement of oil-palm varieties, and more particularly the evolution by selection of a variety which will give a maximum yield of palm oil. The aim therefore is to increase the pulp or pericarp at the expense of the kernel, since it is held that palm oil is of more value than palm kernel oil, and is likely to be still more so if the present research work on the production of an edible palm oil is completely successful. The best varieties at present known, *e.g.* Pisifera and Ceredia (A. Chevalier), will be used as a starting-point, and it is hoped by judicious selection, breeding, and proper cultivation in plantations, instead of happy-go-lucky native methods, to increase largely the yield of palm oil, and also improve its quality to such a degree that an edible grade can be obtained without the need of any subsequent chemical refining. Another important aim is to achieve a variety which will mature early. At present an oil palm in West Africa must be about five years old before commencing to bear fruit, although in the Dutch East Indies (east coast of Sumatra) they are reported to come into bearing at three years. On the other hand, in the East Indies, the seed takes much longer to germinate—six to nine months as compared with five or six weeks in West Africa.

The possibilities of plant research in connexion with many important economic products are now realised, and these experiments in French West Africa will be watched with interest, although, of course, some years must elapse before certain and definite results can be obtained.

Reference has been already made to the Dutch East Indies, where similar work has been undertaken both in Java and in Sumatra for many years. Doubtless also the big English firms interested in African palm oil are fully alive to the importance of this kind of research, and as a matter of fact they initiated experimental plantations years ago, but no results have been published, for obvious reasons.

The East Indies and also Malaysia have now entered the lists as serious rivals to West Africa in supplying the world with oil-palm products, and in some respects they seem to have an advantage over West Africa, but assuming that natural conditions of soil and climate are approximately equal, the deciding factor will be the success or otherwise of these plant-breeding experiments.

[1] Bull. des Matières Grasses de l'Inst. Col. de Marseille, 1921, 9 and 10, 145-158.

The French Dye Industry.

THE issue of *La Nature*, April 15, contains an interesting summary of the French dyestuff industry, particular attention being paid to progress made since 1914. In 1913, 2000 tons of dyes, of the value of seven million francs, were imported. Eighty-five per cent. came from Germany and ten per cent. from Switzerland. The balance of the consumption of 9000 tons represented French manufacture. It is pointed out, however, that the dyestuff factories of France, of which there were four, were almost completely dependent on Germany for intermediates, the home production of which represented scarcely ten per cent. of the requirements. There were in addition German works which received intermediates or even finished dyes from Germany. The article refers to the ready adaptation of the dye works in Germany to the manufacture of munitions during the war, and does not omit to point out that, without the means of obtaining synthetic nitric acid, which the enemy had also perfected, his dye works would not have been of the slightest use to him.

The French efforts during the war are described at length. In April 1916 the Syndicat National des Matières Colorantes was established, which had relations with the State and further arranged to take over after the war the national factories used in the manufacture of explosives. The Compagnie National des Matières Colorantes et de Produits Chimiques was constituted in January 1917 and at once set to work. Two factories rapidly grew up, the first at Nogent-

les-Vierges on a semi-technical scale, and a large factory at Villers-St-Paul, with a contemplated capacity of 4000 tons of synthetic indigo a year. This was abandoned during the German advance in 1918 and the material removed to Lyons, but it has again been set in operation, and as a result of intensive work, the total production of the French factories had grown from 175 tons in 1919 to 765 tons in 1920. Since that time the production has decreased on account of the economic crisis, although the capacity of production is now stated to exceed 13,000 tons. With a few exceptions, dyes of all the main types are manufactured and progress is being made.

The company has two large centres of production. The Oissel Works, installed at the old national factory, with an area of 39,000 sq. m. of buildings, is connected with the main line from Paris to Rouen. The power is generated by turbo-alternators of the most modern type, each of 1000 kilowatts. The factory is at present making intermediates, of which more than sixty are being produced, together with sulphur dyes and azo-dyes. These are produced directly from the intermediates without isolation of the latter from solution.

The second works is that at Villers-St-Paul, with an area of 35,000 sq. m. of buildings, on the main line from Paris to Compiègne. A very modern boiler plant is installed, which when complete will consume 300 tons of coal daily. In this works are made the dyes which require special apparatus, such as indigo and alizarine, phthalic acid and basic dyes derived from it, triphenyl and diphenylmethane dyes, pyrazolone dyes, etc. Vat dyes are also made, and there are large research laboratories.

At Saint-Denis the old works has been enlarged, while a new works at Isère grew up during the war. It is stated that prices are now high owing to high costs of raw materials, and the yields could also be improved by the further efforts of the chemists, and particularly of the engineers.

The Metallic State.

RECENT advances in our knowledge of the structure of the atom have added very little to the elucidation of the nature of the metallic state, and in this connexion a very suggestive paper by Prof. C. A. Kraus, in the June number of the Journal of the American Chemical Society, will be of interest. According to modern views the metals owe their characteristic properties to the presence of negative electrons free to move within the body of the metal. Electronegative elements, such as chlorine, owe their characteristic property of forming anions to the fact that they are capable of forming stable complexes (the ions) with one or more negative electrons. Metallic properties may be expected only in such substances as do not contain sufficient electronegative elements to engage the negative electrons supplied by the more electropositive constituents, or otherwise, in which electronegative elements are lacking. The smaller the affinity of an element or group for the negative electron, the more electropositive will it appear, and the more readily will it enter into reaction with more electronegative elements.

The association of negative electrons with positive metallions, which is supposed to make up the structure of a metal, has some resemblance to a salt. At very low concentrations the negative electron may no longer possess the freedom of motion characteristic of the metallic state, and it is known, for instance, that mercury vapour is a very poor conductor. The metal may under such conditions exhibit salt-like properties, and intermetallic compounds may also show resemblances to salts. There are many such compounds which have properties in harmony with this view. The more electronegative elements in such compounds are supposed to have a negative charge. The compound Na_3Sb is then similar to Na_3N or Na_3P. The question is raised whether the apparent deviations of intermetallic compounds from the valency relations may not be due to the tendency of electronegative elements to form complexes. This is shown in the compounds NaN_3, KI_3, etc., and it is suggested that something of the kind occurs in such compounds as Na_4Sn, Na_2Sn, Na_4Sn_9, $NaSn$, and $NaSn_2$. The atoms in such complexes, however, may not all function in the same manner. The property of metallicity is not an atomic one; it is due to the negative electron, and the rôle of the positive constituent is a secondary one.

Many reactions in liquid ammonia solution, and the existence of substituted ammonium amalgams and substituted ammonium radicals in liquid ammonia solution, support the views expressed. As an example it is stated that tellurium reacts with a solution of sodium in liquid ammonia to form a white crystalline precipitate of the typical salt-like compound Na_2Te. On further addition of tellurium this goes into solution with the production of complex tellurides, Na_2Te_2 and Na_2Te_4, which form strongly coloured solutions, similar to those of alkali-metals, and when precipitated from solution exhibit metallic properties.

University and Educational Intelligence.

LONDON.—At a meeting of the Senate on July 19, Dr. J. C. Drummond was appointed to the University chair of biochemistry tenable at University College. Dr. Drummond graduated from East London College with first-class honours in chemistry, and has been research assistant in the Physiological Laboratory at King's College and assistant analyst in the Government Laboratory (Foods Department). He has also conducted research work at the Cancer Hospital, and has been since 1920 University reader in physiological chemistry at University College.

PROF. ADRIAN STOKES was appointed to the Sir William Dunn chair of pathology tenable at Guy's Hospital Medical School. Prof. Stokes has held the posts of assistant to the professor of pathology at Dublin University and pathologist to the Royal City of Dublin Hospital, while since 1919 he has been professor of bacteriology and preventive medicine at Dublin University. Two years ago he worked with the Rockefeller Commission on Yellow Fever in Nigeria.

The following doctorates were conferred:—*D.Lit.*: Mr. W. I. Moore, King's College, for a thesis entitled "Education and Social Systems, English and French: A Study of Educational Effort and Opinion 1750-1810"; *D.Sc., in Botany*: Miss Dorothy Haynes, King's College and the Imperial College—Royal College of Science, for a thesis entitled "(1) Electrical Conductivity as a Measure of the Content of Electrolytes of Vegetable Saps, and (2) the Action of Salts and Non-electrolytes upon Buffer Solutions and Amphoteric Electrolytes and the Relations of these Effects to the Permeability of the Cell"; *D.Sc., in Physics*: Mr. W. E. Curtis, King's College, for a thesis entitled "The Structure of the Band Spectrum of Helium"; Mr. B. A. Keen, University College, for a thesis entitled "The Physical Properties of Soil"; Mr. F. H. Newman, for publications entitled "Active Modification of Hydrogen and Nitrogen produced by

X-rays," "A New Form of Wehnelt Interrupter," and other papers; Mr. H. R. Nettleton, for a thesis entitled "On the Absolute Measurement of the Thomson Effect," and other papers. *D.Sc. (Engineering)*: Mr. Herbert Moss, the Imperial College—Royal College of Science, for a thesis entitled "Air Consumption and B.H.P. of Aero-Engines."

Mr. H. G. Wells has accepted the invitation of the Labour Party of the University of London to offer himself as the candidate of the Party at the election for a representative of the University in the House of Commons to be held after the retirement of Sir Philip Magnus at the end of the present session of Parliament. Mr. Wells occupies such a distinguished position in the world of literature and among leaders of thought to-day that his early work in science and education is often overlooked. He was a student at the Royal College of Science, South Kensington, in 1884–87, and was the first president of the Old Students' Association of the College. He took his B.Sc. degree with honours in zoology in 1890, and his first book was a "Text-book of Zoology," written particularly for London University students while he was a teacher of the subject. He is a fellow of the College of Preceptors, and for a short time edited the *Educational Times*. Throughout his career he has been a steadfast supporter of scientific methods in schools and government, and in his books has pleaded the cause of scientific education and research with eloquence and conviction. It is not too much to say that no graduate of the University of London possesses such a rare combination of brilliant literary power and scientific thought or has used these gifts with greater effect than has Mr. Wells in his many and various works.

It is announced in *Science* that by the will of Seymour Coman, of Chicago, the University of Chicago is made trustee of his residuary estate, about 29,000*l*., the net income from which is to be used for scientific research with special reference to preventive medicine and the cause, prevention and cure of diseases. The bequest is to be known as the Seymour Coman Research Fund. By the will of Alexander D. Thomson, of Duluth, Minnesota, the sum of 20,000*l*. is bequeathed to the University of Minnesota for use in the medical department. It is also stated that Wake Forest College School of Medicine, North Carolina, is entitled to receive the principal of a trust fund, amounting to 275,000*l*., which was created in 1892 by Jabez A. Bostwick, a director of the Standard Oil Company.

A summer course in the Austrian Tirol of unusually wide interest is being organised by the directors of Leplay House, 65 Belgrave Road, Westminster, S.W.1. The course will be of the nature of a civic and rustic survey, and for this purpose the party will be divided into groups each of which will take one particular aspect of the work. Mr H. J. E. Peake, president-elect of the Anthropological Section of the British Association for the Advancement of Science, has undertaken to direct the group studying the anthropological aspects; Dr. M. Hardy will organise a survey of plant life and agriculture, while other sections will deal with the geology, physiography, history and sociology of the district. Group meetings and gatherings of the whole party will frequently be held for the purpose of discussing and comparing results, which when assembled and collated should provide a valuable record of natural conditions and life in the Tirol. The tour will commence on August 4 and will last four weeks, although it is possible to arrange for a shorter course of two weeks.

Calendar of Industrial Pioneers.

July 31, 1884. Charles Manby died.—The eldest son of Aaron Manby, one of the pioneers of iron ship-building, Charles Manby was engineer of the first iron steamer which crossed the English Channel, and after gaining experience in his father's gas and iron works in France returned to England, and from 1839 to 1856 rendered valuable services to the engineering world as secretary to the Institution of Civil Engineers.

August 2, 1910. Oscar Guttmann died.—Hungarian by birth, Guttmann became editor of an Austrian mining journal, practised on the continent as a chemical engineer, and eventually settled in England, where he erected several works for the manufacture of explosives. He wrote and lectured on explosives, on which he was a recognised authority, and was elected a vice-president of the Institute of Chemistry.

August 3, 1792. Sir Richard Arkwright died.—Born at Preston, December 23, 1732, four years before Watt, Arkwright was responsible with Watt for the great industrial developments in England in the latter part of the eighteenth century which enabled this country to withstand the tremendous drain on her resources due to the Napoleonic wars. Starting life as a barber, Arkwright became a hair merchant, and about 1767 gave himself up to inventions in cotton spinning. Two years later he patented his "spinning frame," "the first adequate example of those beautiful and intricate mechanical contrivances which have transformed the whole character of the manufacturing industry." He is also regarded as the founder of our factory system.

August 3, 1880. Mungo Ponton died.—A Writer to the Signet and a founder of the National Bank of Scotland, Ponton through ill-health retired from business and devoted himself to science. In 1839 he made the important discovery that the action of the sun renders bichromate of mercury insoluble.

August 3, 1906. Sir Alexander Moncrieff died.—Educated at the universities of Edinburgh and Aberdeen, Moncrieff became an officer in the Forfarshire Militia and saw active serve in the Crimean war. He afterwards became known as the inventor of the Moncrieff disappearing gun-carriage and the hydro-pneumatic system of recoil.

August 4, 1921. Samuel Alfred Varley died.—A member of a famous family of electricians and one of the pioneers of the dynamo, Varley made numerous experiments on submarine telegraph cables. In 1866 he made a self-exciting dynamo with soft iron magnets, and ten years later patented the compound-wound dynamo.

August 5, 1729. Thomas Newcomen died.—A native of Dartmouth and born in 1663, Newcomen is believed to have been a blacksmith. He became associated with Thomas Savery in his attempts to use steam for pumping, but it was Newcomen's own great invention of the atmospheric steam-engine which furnished the model for pumping engines during the eighteenth century. His first engine appears to have been erected at Dudley Castle in 1712. Newcomen died in London and was buried in Bunhill Fields.

August 5, 1876. James Freeburn died.—Freeburn enlisted in the artillery in 1825 when seventeen years of age, and rose to the rank of sergeant-major. Turning his attention to the exploding of shell he brought out a series of metal and wood fuses for time or percussion which, after various improvements, were adopted. Freeburn after thirty years' service was retired with the rank of honorary captain.

E. C. S.

Societies and Academies.

London.

Geological Society, June 28.—Prof. A. C. Seward, president, in the chair.—C. E. **Tilley**: The petrology of the metamorphosed rocks of the Start Area (South Devon). The rocks of the Start area comprise a group of mica- and quartz-mica-schists, together with a great development of green schists of basic composition. They can be divided into lower mica- and quartz-mica-schists, green schists, and an upper group of mica- and quartz-mica-schists. The field relations of these rocks show that the dominant feature of the area is an anticlinorium with an axis plunging westwards. The rocks are sharply differentiated from the slates and phyllites of Devonian age in the Kingsbridge area immediately to the north; the two areas are probably separated by an important boundary of dislocation. The aluminous sediments are typically quartz-muscovite-chlorite types, the grade of metamorphism corresponding to the formation of biotite not being reached. In the composite type of sediment, where tufaceous material is included, the highest stage of metamorphism is reached in the muscovite-chlorite-garnet-albite-schists. The garnet is rich in the spessartine molecule, and the reversal of the normal biotite-garnet order in an increasing grade of metamorphism is ascribed to the presence of manganese.—A. R. **Dwerryhouse**: The glaciation of the counties of Antrim, Down, and parts of Armagh, Londonderry, Tyrone, Monaghan, and Louth in Ireland. The deposits consist of boulder-clay, gravel, and sand, and are divided into two groups according to their direction of transport: those derived from the north-east and carried by a glacier which flowed by way of the Firth of Clyde from Scotland; and those the source of which lay to the west, carried by an Irish ice-sheet having its origin in Donegal. The former are characterised by the riebeckite-bearing rock of Ailsa Crag with granites, quartz-porphyry, and pitchstone from Arran; the latter contain boulders of igneous rocks from County Tyrone. Delta-terraces and overflow-channels show that ice-dammed lakes existed in the district. Moraines occur, the most conspicuous being those near Armoy in Antrim and near Garvagh in Londonderry. The earlier glaciation was effected by the ice from Scotland, which reached south-west to the town of Monaghan and the eastern flank of Slieve Beagh. The Scottish ice was then gradually replaced by that from Donegal. The latest phase of the glaciation was a second advance of the Scottish ice, which formed definite frontal moraines in the neighbourhood of Ballymoney and Armoy, and the establishment of a small local centre of glaciation in the neighbourhood of Trostan, the highest mountain in County Antrim. Glaciation was probably continuous.

Dublin.

Royal Dublin Society, June 27.—Dr. J. A. Scott in the chair.—H. H. **Jeffcott**: The electrical design of A.C. high tension transmission lines. A method is given for calculating the performance of high tension transmission lines, based on direct evaluation by complex quantities. The process can be systematised into an arithmetical routine. Examples of its application to specific problems are given.—T. **Dillon**, Rosalind **Clarke**, and V. M. **Hinchy**: Preliminary experiments on a chemical method of separating the isotopes of lead. Lead chloride containing thorite lead was treated with magnesium ethiodide and the resulting lead tetraethyl, and metallic lead were re-converted into lead chloride. This material was treated with magnesium ethiodide and comparative atomic weight determinations of the lead from the two fractions of lead chloride obtained showed a difference of atomic weight of 0·2 to 0·3.—T. **Johnson** and J. G. **Gilmore**: (1) The lignite of Washing Bay, Co. Tyrone. Lignite was found at various depths, but especially at 1000 ft., in the Washing Bay core. It is all coniferous in nature and is referred to *Sequoia Couttsiae*, Heer, of which cones, seeds and foliage have been previously described from the same beds. The Lough Neagh lignite originally described by Unger as *Peuce Pritchardi* may prove to be a Sequoia also. (2) Libocedrus and its cone in the Irish Tertiary. A foliage impression of *Libocedrus salicornioides* showing characteristic stomata and epidermal papillæ is described. The specimen was found at a depth of 904 ft. in the clay core of the coal-bore at Washing Bay, Lough Neagh. The foliage shoots and cones of the same species from the interbasaltic beds of Ballypalady, Co. Antrim, are also described, the specimens being preserved in the Belfast Museum. Restorations of the wood show agreement between the Irish material and that from Leoben in Styria and with recent Libocedrus, of which *L. decurrens* (California) and *L. chilensis* are the nearest living representatives.

Paris.

Academy of Sciences, June 26.—M. Emile Bertin in the chair.—P. A. **Dangeard**: Researches on the structure of the cell in the iris. In an earlier communication the author has suggested that the term chondriome really comprises three different types of elements named vacuome, plastidome and spherome. This is confirmed by a study of the leaf of *Iris germanica*. The structure is best observed on unstained specimens. Fixing and staining methods are liable to cause distortion, and have, in the author's opinion, led to erroneous interpretations of the cell structure in the past.—J. **Costantin**: Acquired heredity. The wild potato is a mountain species, growing in the Andes up to 4000 metres, and the formation of tubercles is caused by a fungus. In the absence of this fungus, the hereditary characters can be maintained intact only if the plant is maintained under the climatic conditions which it requires. Thus the variety "Up to date" degenerates in Algeria, but has been maintained without change for twenty-five years in Scotland.—Pierre and Louis **Bazy**: Vaccination before operation. Preventive auto-vaccination is suggested as preferable, except in cases requiring immediate operation, to preventive serotherapy.—Maurice **d'Ocagne**: Transparent nomograms.—A. **Rateau**: Calculation of the variations of the level of an aeroplane due to a variation of its weight or to the use of a turbo-compressor.—Henri **Jumelle**: The group of *Chrysalidocarpus lutescens*.—M. Amé Pictet was elected correspondant for the section of chemistry in the place of the late Prof. Ph. A. Guye.—H. **Mineur**: Certain functional algebraical equations.—Torsten **Carleman**: The problem of moments.—Paul **Lévy**: The law of Gauss. Correction of an error in an earlier note (March 27).—W. **Margoulis**: Transparent abacus with orientation.—Gaston **Bertrand**: The law of Riemann, the perihelion of Mercury, and the deviation of light. Measurements of high precision are necessary to decide between the formulæ of Einstein and Riemann.—Charles **Nordmann** and Le **Morvan**: Observations of stars of the N type and especially of a star with a very low effective temperature, by means of the heterochrome photometer of the University (Paris). One of the three stars examined (112, 559, Henry Draper Memorial Catalogue) has an effective temperature of 2160° absolute (1887° C.), the lowest temperature of any star measured.—N. **Vasilesco Karpen**: A new evaluation of the internal

pressure of liquids. The criterion of the association of the molecules in a liquid.—B. **Szilard**: The direct estimation of very small quantities of radium by the penetrating rays. An application of the portable electrometer described in a previous paper (June 19). Using 500 grams of material containing 10^{-9} grams of radium per gram, the error of estimation is within 2·5 per cent.—Paul **Pascal**: Magnetochemical research on the constitution in mineral chemistry. Acids containing arsenic.—G **Gire**: The dissociation of barium chloroplatinate The dissociation pressures of this salt were measured at temperatures ranging between 128° C and 665° C., and the heat of reaction calculated.—A **Demolon**. The accessory elements in Thomas slag. Besides phosphate, basic slag contains lime, magnesia and manganese Determinations of the solubility of the slag in various solvents (water, sugar-solution, carbolic acid, etc.) have been made and the results given as curves with time as abscissæ—L J **Simon**. Oxidation by mixtures of sulphuric acid and chromates The use of silver chromate with sulphuric acid gives a more complete combustion of organic compounds than alkali chromates and sulphuric acid. The modification is especially useful in the analysis of bodies containing the acetyl group Mlle. Hélène **Billon**: The action of trimethylene chlorobromide on some ketones of the fatty series.—R **Locquin** and Sung **Wouseng**: The transformation of the tertiary ethylenic alcohols (linalool type) into primary ethylenic alcohols (geraniol type)—F **Kerforne** and L **Dangeard**: The palæozoic rocks brought up by the dredge of the *Pourquoi-Pas?* in 1921 in the western English Channel—F **Ehrmann** The discovery of the Silurian with graptoliths and the Devonian with tentaculites at Beni-Afeur (south of Djidjelli, Algeria). —Ch. **Gorceix** The distribution of temperature in Lake Bourget—Pierre **Nobécourt**. The mechanism of the parasitic action of *Penicillium glaucum* and of *Mucor stolonifer* Experiments on the artificial ripening of sterilised fruits by inoculation with the two moulds named above. The action appears to be due to a secretion of enzymes, and the action takes place only in acid media Joseph **Bouget**: Observations on the most favourable altitude for the coloration of flowers—Jean **Dufrenoy** Tumefaction and tuberisation (in plants)—W **Mestrézat**, Pierre **Girard**, and V. **Morax**. The elective ionic permeability of the cellular elements Experiments on the cornea of the dog and rabbit prove that the permeability of the cells to electrolytes is an ionic permeability and that it is elective M **Doyon**. Comparison of the effects of the nucleic acids and of the antithrombine of peptone plasma on the coagulability of the blood circulating in the frog—L **Panisset** and J **Verge**. Idiosyncrasy and anaphylaxy Maurice **Nicloux** and Georges **Welter**. Does cyanic acid exist in the blood? Attempts to show the presence of cyanic acid in the blood and lymph gave negative results—A. **Weber**: Influence on the development of the eggs of a batrachian of a substance extracted from the fertilisine of the eggs of a fish—A. **Lécaillon**. Variability of the species and the experimental creation of new races in the silk-worm of the mulberry tree.—R. **de La Vaulx**: The appearance of intersexual forms in a strain of *Daphnia magna*, and on the probable determinism of the phenomenon.—A **Vandel**. Geographical spanandria in a terrestrial isopod—R. **Hovasse**: A Peridinian, an intracellular parasite of the Vellela.

MELBOURNE

Royal Society of Victoria, April 8.—Mr. F. Wisewould, president, in the chair.—F. **Chapman**: New or little-known Victorian fossils in the National Museum. Pt. XXVI. Some Tertiary Mollusca. Fourteen new species of Pelecypoda and Gasteropoda are described and the distribution and diagnoses of eight other forms are discussed. So far back as Oligocene and Miocene times there existed many species of Mollusca which are so closely related to living forms that they are evidently the direct ancestors of present molluscan types. Others have migrated from the Bassian area and are now found only as varietal offshoots in warmer Australian waters. Certain species dating back to the older Tertiary are now found living in lower latitudes of the Southern Ocean—H. B. **Williamson**: An addition to the flora of Victoria. A new species of Helichrysum, *H. Gatesii*, has been found growing on dry hillsides a few miles from Lorne by the Rev. A. C. F. Gates. The plant resembles a Leptorrhynchus, but approaches very closely to *Helichrysum podolepideum*, a Central Australian species. It is probably a connecting link between sections Oxylepis and Chrysocephalum of the genus.—J. **Shirley** and C A **Lambert**: *Coprosma Baueri*, End. The leaf pits were examined, but no acarids were found. The pits are of teratological interest only, as the plant no longer lives under xerophytic conditions—G. H. **Hardy** Notes on some Australian Asilidæ (Diptera) in the collection in the National Museum A new species of Neoitamus is described, and notes and new descriptions on the remaining fifty-four species and one subspecies in the collection are given—A. J. **Turner** Studies in Australian Lepidoptera. A number of species obtained on the Claudie River in the Cape York Peninsula, N. Queensland, in the National Park, Queensland, and in Tasmania are described. Revisions of orders previously described are given, together with descriptions of some new forms.

SYDNEY

Royal Society of New South Wales, May 3.—Mr. E. C Andrews, president, in the chair.—E. C. **Andrews**: Presidential Address. The coral-bearing limestones of the Cainozoic within the Pacific are of two types, namely, Tertiary and Pleistocene. The Tertiary consist of sediments deposited unconformably upon sinking surfaces of submarine erosion, whereas the Pleistocene, although deposited unconformably along the Cainozoic, have grown in clear water away from the influence of silt-laden streams. No signs of bedding occur in them, and they are amorphous, massive, and homogeneous Cliffs one thousand feet in height exist, which reveal no sign of structure To understand the origin of coral reefs, it must be remembered that the continents bordering the Pacific have grown mainly towards that ocean in the form of land waves or undulations commencing at the continental nuclei, such as South-Western Australia, the Canadian Shield, Brazil, and Siberia. Island groups such as Japan, New Zealand, Fiji, and Tonga represent extensions of earth waves of this type. These earth undulations have grown as oscillatory vibrations with a progressive but slow radial movement of the major wave axes. Each island group forms a compound earth wave. Generally, the western islands and the larger individual groups, such as New Caledonia and Fiji, have been stable during the later Pleistocene, whereas the eastern satellitic islands and islets have moved up and down in vibratory undulations during the same period The true coral reefs of the Pacific indicate the peculiar vibrations and undulations of movement in these relatively unstable masses of the island groups and also the growth of great barriers and fringing reefs, such as the Great Australian Barrier, on submerged areas of submarine erosion. Generally, Pleistocene coral reefs are amorphous and non-bedded, and have been formed on submerged surfaces of submarine erosion at various stages.

General and Specific Sanitation.

ALTHOUGH hookworm infection (anchylostomiasis) is so rare in this country as to be unknown except among miners, the principles governing its control give an illustration of the relationship between specific and general control over infection, which is not without value for British hygienists. For this reason a monograph recently issued by the Rockefeller Institute for Medical Research[1] is deserving of attention. Hookworm disease is chiefly a rural disease in Brazil as elsewhere, and is most prevalent where there is complete disregard of elementary sanitation, especially in warm climatic conditions, which favour the life of the hookworm embryo in the soil, and encourage workpeople to go barefooted.

Dr. Smillie's investigation shows that hookworm disease is most common in the ages between fifteen and forty. It may be correctly described as an industrial disease, as it occurs chiefly in unshod field-workers. This fact comes out more clearly when a distinction is drawn, as it should be, between hookworm infection and hookworm disease. The importance of this distinction is gradually becoming appreciated in public health. In diphtheria it forms an essential consideration; and rational measures cannot be devised for the prevention of tuberculosis, which have no regard for this distinction. In male children under ten years of age the average number of intestinal hookworms per person was 39, increasing to 169 between ten and twenty, and over 200 in men between twenty and forty years old. The injury to health occurs chiefly in the persons showing heavier incidence of intestinal worms.

The work of Looss and his successors proved that the chief mode of hookworm infection is through the skin, by its contact with fæcally contaminated moist earth, the mouth being an incidental and altogether unimportant channel of infection. This important fact in natural history suggests the two chief methods of control of the disease, the provision of latrines and covering for the feet. The third line of action, that of treatment of infected persons, has relatively smaller importance; and in Dr. Smillie's judgment treatment may properly be limited to field-workers, and may be disregarded for persons under five and over fifty-five years of age. Hookworm disease being an industrial malady, the construction of latrines in the working fields as well as domestically is indispensable if the disease is to be controlled; and the difficulty of reform in this direction is seen in the statement that there are practically no latrines in rural Brazil. As regards the second method of control, it has been found that the use of a crude pair

[1] "Studies on Hookworm Infection in Brazil, 1918-20." Second paper by Dr. Wilson G. Smillie (Monographs of the Rockefeller Institute for Medical Research, No. 17, May 12, 1922).

of half shoes by farm-workers has reduced infection to less than one-tenth of the usual rate suffered by those who did not wear shoes.

Only a few outstanding points in this valuable report have been cited, but enough has been given to show that in hookworm disease we have a notable illustration of the close connexion between elementary sanitation and the prevention of disease. In England we associate this connexion chiefly with diarrhœa and enteric fever, and William Budd's researches will always furnish the classical illustration of the close relations between defective latrine accommodation and the spread of infection as soon as typhoid fever is introduced into a village. The association is probably wider than is usually suspected. The relation of excessive diarrhœa to the continuance of conservancy systems in English towns and villages has been repeatedly emphasised, and there is strong reason for assuming a similar association of these systems with excessive pneumonia in young children.

But the hookworm story emphasises even more the importance of exact knowledge of the infecting agent. The provision of shoes or even their compulsory wearing is a novelty in sanitary administration from a British point of view; but it appears to be the most urgent need where hookworm disease is endemic. So, likewise, the fact that hookworm disease is an occupational disease shows where preventive work is chiefly needed, while the distinction between incidental infection and actual disease points to the persons among whom administrative control must be chiefly attempted. These contentions are illustrated in the paper by the wasted effort displayed in such public health work as the "swat-the-fly" campaign, in which a vast amount of effort and much money are expended in fruitless endeavours to eliminate flies by wholly illogical methods.

The Vegetation of High Asia.

Southern Tibet: Discoveries in Former Times compared with my own Researches in 1906–1908. By Sven Hedin. II. *A List of Flowering Plants from Inner Asia, collected by Dr. Sven Hedin, determined by various authors, and compiled by C. H. Ostenfeld and Ove Paulsen.* Pp. 25 + 100 + 8 plates. (Stockholm: Lithographic Institute of the General Staff of the Swedish Army, 1922.) 30 marks.

KNOWLEDGE of the vegetation of High Asia is now extensive. The climate, while leaving something to be desired in other respects, favours the preparation of botanical specimens, and travellers in the inclement uplands of Tibet and the Pamirs have supplied much material for herbarium use. Yet, owing to circumstances beyond their control, this material compares unfavourably with that secured by explorers in temperate and tropical regions. As a result, our acquaintance with the flora of High Asia is still far from exhaustive.

Geographical reconnaissance involves the investigation of as much ground as an expedition can map, and is thus somewhat incompatible with an intensive study of the vegetation of a given area throughout a round of the seasons. Any combination of the two activities means either that geography must be content with fewer data, or that botany must rest satisfied with indifferent material. The best botanical results of geographical expeditions are obtained during halts made when plants are in active growth.

The traveller in temperate regions may arrange his halts. In the tropics, as in high latitudes and at great altitudes, halts usually depend on meteorological conditions. Those caused by heat or rain coincide with periods of vegetative activity; those due to cold and snow occur when plants are dormant. The arctic-alpine flowering season is, besides, so brief that when the explorer sets out he may find only leaf-specimens; ere his journey ends, he may collect only specimens of plants the seeds of which have fallen. He may, if fortunate, secure complete material of species general along his route but he must be prepared for the possibility that his specimens of local plants are not always identifiable.

The botanical interest in any collection of plants from High Asia is therefore intelligible. Underlying this interest is a hope that new material may resolve old doubts. That hope explains our attitude towards arctic and alpine collections as compared with those from temperate latitudes or moderate elevations. A difference of a few days in the dates on which particular arctic or alpine camping-grounds were visited may give assurance to identifications originally tentative. The value of any High Asian collection is thus enhanced if it comes from districts already carefully investigated.

The importance of a census of the flowering plants found by Dr. Sven Hedin in the course of his various journeys in Inner Asia during 1894–1907 will therefore be readily appreciated. This census, compiled by workers so careful and competent as Prof. C. H. Ostenfeld and Dr. O. Paulsen, affords concrete evidence of the effects upon botanical survey of the exigencies of geographical exploration at great heights, and exemplifies the disadvantages against which the traveller on lofty uplands must contend.

The praiseworthy pains the authors have taken to identify many incomplete specimens have been more than justified by their results. Notwithstanding their care, the compilers have felt debarred from suggesting

specific names in the case of eleven, or 4 per cent. of the 275 plants enumerated. If, to these we add the cases in which specific determination remains more or less doubtful, we have a total of 27, or nearly 10 per cent. of the whole. The authors have laid those who may study this census under a lasting obligation by recording the precise condition of the material available and thereby indicating why, as well as where, doubt attaches to certain identifications.

The imperfection of much of Dr. Hedin's material has induced the authors to restrict themselves to a taxonomic enumeration of the plants actually found by that eminent traveller in East Turkestan, the Pamirs, and Tibet, and to regard their work as supplementary to that of Dr. Hemsley [1] and Madame Fedtschenko.[2] Other considerations may have weighed with workers who are recognised as authorities both on plant-distribution and plant-association, when deciding that phytogeographical or ecological discussion is not yet feasible.

The census shows that Dr. Hedin collected 57 distinct plants in East Turkestan, 72 in the Pamirs, and 185 in Tibet, but that two only of the plants enumerated were found by him in all three regions; only one not met with in Tibet was found both in East Turkestan and the Pamirs, and only eight not met with in the Pamirs are recorded both from East Turkestan and Tibet, while no fewer than 27 not met with in East Turkestan are recorded both from the Pamirs and Tibet.

These figures are not surprising when regard is had to the fact that all the Pamir plants were collected at elevations of 12,000-15,000 feet and all the Tibetan ones were found at elevations of 8500-17,000 feet, whereas 44 of the 57 plants reported from East Turkestan were met with at altitudes of only 2750-3500 feet. Conformity as regards elevation may account for the appreciable common element in the Pamir and the Tibet vegetations; disparity in this respect may explain the relative isolation of East Turkestan. That isolation may indeed be greater than the census suggests. All the East Turkestan plants reported from altitudes exceeding 3500 feet were found in one or other of three localities. The thirteen plants in question include one of the three recorded as common to East Turkestan and the Pamirs and seven of the ten recorded as common to East Turkestan and Tibet.

One of these three localities is Toghde-gol, 9100 feet, in southern Tsaidam. This locality is cited in the census for four plants. Only in the case of two of these is the place said to be in East Turkestan; under the others it is said to be in Tibet. Another of the localities is Bash-kurgan, 8750 feet, south of Lop-nor, which is cited for five plants. In connexion with two of these the place is said to be in East Turkestan, under a third it is stated to be on the East Turkestan-Tibet frontier, and in connexion with the two remaining plants the locality is placed in Tibet. The third locality, Tatlik-bulak, 6500 feet, is mentioned in connexion with eight plants. Here we have no such formal inconsistency; on each occasion the place is attributed to East Turkestan. But this does not remove all doubt; Tatlik-bulak lies south-east of Lop-nor and therefore farther east than Bash-kurgan.

It is possible that this discrepancy of statement merely reflects a difference in point of view. In floristic studies it is often convenient to respect political boundaries; in phytogeographical ones it is always desirable to recognise natural frontiers. From an ethnic standpoint all three localities may belong to East Turkestan; the evidence of the plants themselves suggests that from a botanical standpoint all three belong to Tibet. However this may be, the census prepared by Prof. Ostenfeld and Dr. Paulsen appears to justify one general conclusion. While it is clear that East Turkestan can be properly included in the region our authors speak of as "Inner Asia," it must be excluded from the region for which Dr. Hemsley has employed the term "High Asia."

How deeply we are indebted to Dr. Paulsen for our acquaintance with the vegetation of the western Pamirs, the drainage of which is towards Ferghana and the Oxus, readers of NATURE are already aware. Regarding the plants of the eastern Pamirs, the streams of which flow towards Yarkand, we have hitherto known little beyond what was to be learned from a few specimens gathered by Sir F. E. Younghusband thirty years ago in the Pamir of Taghdumbash. All save one of the Pamir plants in Dr. Hedin's collections are reported from the eastern half of the region; the evidence they afford is thus of unusual importance.

Unfortunately, that evidence is still far from complete. From the Taghdumbash Pamir, which from its connexions to the south and the east should perhaps prove the most "critical" of these high valleys, we have again to be content with a few specimens. Nearly 30 per cent. of Dr. Hedin's Pamir plants are from the Karakul Pamir, probably the least critical of the eastern valleys. More than 40 per cent. were gathered on the slopes of Mustagh-ata, highest of the Pamir peaks, but in this case it is not clear that all the Mustagh-ata plants were collected in one Pamir. Until the vegetation of these various eastern Pamirs has been investigated as exhaustively as that of the Little Pamir was by Lt.-Col. Alcock during the Pamir

[1] The Flora of Tibet or High Asia: W. B. Hemsley, assisted by H. H. W. Pearson (Journ. Linn. Soc., Bot. vol. xxxv pp. 124-265, 1920).

[2] Flore du Pamir: Olga Fedtschenko (Act. Hort. Petrop., vol. xxi. pp. 233-471, 1903; *ibid.* vol. xxiv. pp. 123-154, 1904; and pp. 313-355, 1905; *ibid.* vol. xxviii. pp. 97-186, 1907; and pp. 455-514, 1909).

Boundary Commission and as that of the Alichur Pamir was by Dr. Paulsen during the second Danish Pamir Expedition, the last word on the vegetation of this region as a whole must be left unsaid. The numbers of plants found by Dr. Hedin in all the eastern valleys visited by him falls short of the number which Lt.-Col. Alcock has taught us may be found in a single western one.

The evidence supplied by Dr. Hedin, imperfect though it be, does, however, sustain the general conclusion, based on our acquaintance with the vegetation of the western Pamirs, that while many plants are common to all, some are peculiar to each.[3] Another general conclusion to which the material obtained by Dr. Hedin appears to point is that it may prove more convenient and natural to employ the term "High Asia," restricted by Dr. Hemsley to Tibet, in an extended sense which will include also the "Pamirs."

Tibet is by far the largest of the three regions visited by Dr. Hedin; he collected there twice as many plants as he found in the Pamirs, and three times as many as he gathered in East Turkestan. The plants from Tibet which the authors have been compelled to describe as new are five times as numerous as the new species reported from both of the other regions. The authors of this census are therefore fully justified in remarking that its main interest lies in the Tibetan plants therein discussed. These facts notwithstanding, it is more impossible to deduce conclusions regarding the vegetation of Tibet from the evidence here supplied than it is to do so in the case of East Turkestan or of the Pamirs. The phytogeographical indications are sometimes as inconsistent as in the case of East Turkestan and are, if possible, more inexplicable than they are as regards that region. Localities are at times placed in Inner Tibet with no indication of latitude or longitude, and therefore with only imperfect clues as to their precise situation. When more precise indications are supplied, Inner Tibet is now given as synonymous with Northern, anon as synonymous with Eastern Tibet. Certain localities are said in one case to be in North Tibet, in another to be in East Tibet The list itself forms part of the sixth volume of a work entitled "Southern Tibet," yet it does not include any plant said to have been collected in South Tibet.

Perhaps the most interesting individual species in the list is one which Prof. Ostenfeld has proposed to treat as the type of a new genus, Hedinia Though thus characterised, this plant, as it happens, is not a new discovery. It is one that so long ago as 1852 was referred by Dr. T. Thomson to the Cruciferous genus Hutchinsia, with the characters of which it conforms so indifferently that in 1861 it was transferred by Sir J. D. Hooker to the genus Capsella as admittedly a very aberrant member. In 1904 Mr. W. Lipsky was so impressed by the unsatisfactory character of both these suggestions that he transferred the plant to the genus Smelowskia. With this particular genus, however, the plant has less natural affinity than it has with either Capsella or Hutchinsia. The treatment now accorded the plant by Prof. Ostenfeld is certainly more convenient than any hitherto proposed. It is to be hoped that it may also prove to be more natural and that it may provide a lasting memorial to the explorer whose name it is intended to perpetuate.

Alcohol as a Fuel.

Power Alcohol: Its Production and Utilisation. By G. W. Monier-Williams Pp. xii + 323. (London: Henry Frowde and Hodder and Stoughton, 1922.) 21*s*. net.

THE enormous increase in the number of engines using motor spirit throughout the civilised world, and the demand for other products of mineral oil, have forcibly directed attention to the great problem of the world's reserves of oil, and to alternative sources of fuels suitable for engines where a fuel of high vapour pressure is necessary. Dr. Monier-Williams deals in his opening chapter with this big problem—the motor fuel question—in a very comprehensive and clear manner. It is shown that while in 1913 the import of petroleum spirit into the United Kingdom was 101 million gallons, by 1920 the imports had reached 200 million gallons. In the United States (where it is said that there is one motor car to every eight of the population) the motor spirit consumption rose from 1200 million gallons in 1914 to 2680 million gallons in 1918.

It is clear that this modern development of locomotion, together with the requirements for aviation, will make further and further demands upon Nature's not inexhaustible reserves of suitable fuel. Although much has been accomplished in rendering a greater proportion of the crude oil available as fuel, by widening the distillation range, by "cracking" heavier fractions, and by taking out the more easily condensible portions of natural gas ("casing head gasoline"), the world is undoubtedly faced with the big problem of Nature's reserves of oil and the possibility of alternative supplies of liquids of sufficiently high vapour pressure to supplement, or in the long run largely to replace, the motor spirit derived from crude petroleum. Dr. Monier-Williams says "a complete solution of the motor fuel problem can only be found in the opening up of extensive, and as yet unproved, new areas of supply, together with the introduction of fuels derived from other sources than petroleum."

Allowing the exclusion of a liquid fuel produced by inorganic agency, he considers that "contemporary vegetation constitutes the only alternative to bituminous mineral deposits as a source of motor spirit, and it would seem that it must eventually supply (as alcohol) a large proportion of the world's requirements." To-day it is a question of the comparative cost of alcohol and petroleum spirit, and alcohol is at a serious disadvantage. In concluding his first chapter Dr. Monier-Williams cogently observes that "the balance of evidence certainly favours the view that before many years have elapsed the supply of petrol will be permanently unequal to the demand, and that power alcohol, considered from the standpoint of a supplementary and not necessarily competitive fuel, has an undoubted future before it."

The many problems associated with the economic production of fuel alcohol have received a great deal of attention, and the author has given a most complete account of the chemical and economic questions involved. In his later chapters he gives very full information on the results which have been obtained in practice with alcohol, and fuel mixtures containing it, and particular mention should be made of the excellent chapter on the chemical and physical properties of alcohol from the motor fuel standpoint. Here are included the important results which have recently been obtained by Ricardo, Tizard and Pye, and Ormandy.

One of the outstanding problems in connexion with fuel alcohol must be the bearing of excise regulations on its production, and the associated question of denaturing. When duty-free denatured alcohol was legalised in 1855 the duty was only *12s.* per bulk gallon; to-day it is *6l. 3s. 3d.* per gallon of 95 per cent. alcohol. To protect the revenue many onerous conditions have to be applied to production, and these necessarily are reflected in the costs, but some relaxation has already been sanctioned since 1921. It is now possible to import power alcohol as bulk cargo at certain ports, denature it in bond with at least 25 per cent. of petrol, benzol, or other approved substance, and to distribute the spirit without further restriction for power purposes alone. Dr. Monier-Williams deals very fully with these questions of excise supervision and denaturation, but concludes, after summarising the ideal requirements of a denaturant, that no substance has yet been found which fulfils satisfactorily all these conditions.

Whether "Power Alcohol" is considered from the point of view of the chemist, the engineer, or the general reader, it gives a complete and well-balanced consideration to all the problems associated with the production and utilisation. Sooner or later alcohol seems bound to play no small part in our means of transport, but above all it is necessary to-day to maintain a proper sense of proportion, and this Dr. Monier-Williams may justly claim to have preserved. Enthusiastic advocates of a new development so often fail to recognise economic limitations.

J. S. S. B.

Chemistry and Life.

La Chimie et la Vie. By Georges Bohn and Dr. Anna Drzewina. (Bibliothèque de Philosophie scientifique.) Pp. 275. (Paris: Ernest Flammarion, 1920.) Price 7.50 frs. net.

BEYOND a short chapter with general statements concerning colloids, nucleoproteids and lipoids, and a chapter insisting upon the specificity of the chemistry of living animals and plants, chemistry plays no more part in the arguments of the authors of "La Chimie et la Vie" than many other sciences. The authors do not deal with pure chemistry, but with chemical physics—the object of which is to determine the influence exerted by physical conditions such as pressure, temperature and concentration of solutions on the progress or change of direction of chemical reactions. They object to the tendency to localise the various properties of plants and animals to particular chemical substances, and suggest that ferments, hormones, antibodies, etc., may not be specific substances so numerous and varied as the effects they produce; but they may be, on the contrary, various methods of activity of a limited number of substances resulting for the most part from the disintegration of living matter.

The main thesis of the book shows how insolubly bound up with one another are all the various branches of biological science Discussion centres around recent work from practically every branch—chemistry, physical chemistry, zoology, botany, physiology, psychology, general biology, cytology, embryology, medicine, serology. The authors show how fruitful has been the introduction of chemistry to the study of phenomena of life and to what degree chemical physics has restored interest in and revived problems of biology. Some of their own work is recorded briefly. They describe how a double Hydra can be produced from a single Hydra by temporarily depriving the organism of oxygen, and how the symmetry of the Stauridium is altered by a simple change of environment.

The authors consider that the law of van't Hoff and Arrhenius may be applied to vital actions—development of the egg, reproduction, respiration, rhythm of the heart, and growth—and that the "law of reciprocal phenomena" holds for sleep, secretion, movement

and growth. They also attempt to establish a parallelism between form and movement, considering that the same factors acting through the same mechanisms are concerned with both. In the origin of form and in the origin of movement, physics and geometry are working in unison with chemistry.

Immunity, Abderhalden's "ferments of defence," anaphylaxis, agglutinins, hæmolysins, precipitins, the secretions of the interstitial glands of the reproductive organs, and hormones in general receive attention. Interesting experiments of tropisms, of fertilisation by chemical means, of experimental parthenogenesis, and of plant grafting, extend the scope of the book. The authors consider that the substances which kill are at the same time the substances which give life; thus, a tumour is submitted to the same physico-chemical determination as a developing organ.

The attempt to co-ordinate in a readable and instructive form the recent discoveries of biological interest is certainly successful, and the book is inexpensively though well arranged.

Aristotle in English.

The Works of Aristotle translated into English. De Caelo, by J. L. Stocks; *De Generatione et Corruptione*, by Harold H. Joachim (Oxford: Clarendon Press, 1922.) 10s. net.

THE great Oxford version of Aristotle could scarcely have begun to deal with that philosopher's physics and cosmology at a more opportune time than the present. It is only a year or two since Prof. Whitehead, speaking with all the authority that belongs to his utterances on such a subject, warned us that the first explicit beginnings of the "bifurcation" which has infected nearly all subsequent philosophising about Nature and natural science, are explicit in Aristotle, and that the duty of the *Naturphilosoph* of the present day is to put himself back at the Pythagorean standpoint represented by Plato's "Timaeus" and study the "passage" of nature with a mind freed from the prejudices begotten of a substance-attribute metaphysic.

This weighty modern endorsement of Bacon's old complaint that Aristotle corrupted natural science at its sources by his "dialectic," must have set many who know little Greek wishing to have the means of knowing more accurately than can be known from modern summaries exactly what the Aristotelian interpretation of Nature was. The translation of the "De Caelo" by Mr. J. L. Stocks and of the "De Generatione" by Prof. Joachim comes very opportunely to meet the need, so far as Aristotle's astronomical and physical doctrines are concerned. It is to be hoped that we shall not have to wait much longer for the versions of the "Physics," the treatise which expounds the Aristotelian mechanics of the universe, and the "Meteorologica," which deals with the "sublunary" department of cosmology.

The University of Oxford may be highly complimented on producing an English version of the two historically very important works before us, which may be taken by all but specialist scholars as equivalent to the original text. In constituting the actual Greek text, both translators have done excellent work in removing a large number of the singularly infelicitous alterations made by Prantl, the editor of the Teubner editions. Mr. Stocks has given a very generous amount of annotation to the explanation of his divergencies from Prantl; Prof. Joachim, having recently published his own recension of the "De Generatione," naturally makes his version avowedly from that text, and thus escapes the necessity of critical notes. It is perhaps a pity, in view of the appeal his version should make to many who are scarcely likely to possess his text and commentary, that he has not recorded quite briefly at least the more important of his differences from one of the standard texts, *e.g.* Bekker's. Of course it is inevitable that the fuller and more argumentative annotations of Mr. Stocks should at times require him to take sides on disputable points of reading or exegesis, and he himself would, no doubt, be the first to admit that appreciation of the value of his work does not imply agreement with all his decisions on such issues. To agree or disagree in detail would only be possible after a special minute study of Mr. Stocks's notes in conjunction with the Aristotelian text and the commentary of Simplicius.

We note that on one very important point the exact meaning of the original seems to have been misconceived. We believe it can be made clear that the kind of motion of the earth stated in "De Caelo," ii. 293 b 30 ff., to be spoken of by Plato in the "Timaeus," is not "rolling" of any kind. If that had been meant, Aristotle would not have been so careful to say that the "Timaeus" speaks of something different, "motion *at* the centre." It is clear also that axial rotation cannot be meant, for reasons into which space will not permit us to enter. The poetical word used in the "Timaeus" and repeated by Aristotle (ἴλλεσθαι) appears properly to describe "to-and-fro" motion, "oscillation," or "excursion" about a mean position. If we suppose that Aristotle knew, as he could scarcely help knowing, the correct interpretation of the Platonic phrase, we see at once why he is so careful to distinguish this movement of the earth "to and fro" about "the middle" from all theories of movement "round the middle." The point is important, because, in speaking

of movement "round the middle." Aristotle has just mentioned (293 a, 28 ff.) an argument for it which we know, on the authority of Theophrastus, to be Platonic. It follows, therefore, that Plato is included among the "many others" who seem to agree with the Pythagoreans in denying that the earth is "at the middle," and that Aristotle was well aware that the theories Plato ascribes to Timaeus are not necessarily Plato's own theories, as has erroneously been assumed by almost all expositors of Platonism. A. E. T.

A Rock-Desert.

Ministry of Finance, Egypt. Petroleum Research. Bulletin No. 10. *Topography and Geology of Northern Sinai.* Part 6, Session 1919-1920. By F. W. Moon and H. Sadek. Pp. vii+154+51 plates. (Cairo: Government Publications Office, 1921.) P.T. 50.

It is no disparagement to the scientific observations recorded in this volume if we notice its handsome mode of production at the outset. In printing, illustration, and the inclusion of coloured sections, it will bear comparison with the work of any Geological Survey in the world. Two coloured maps on the scale of 1:250,000 are folded in a pocket at the end, and these are mounted on linen, a feature almost unique in official publication.

The researches that are placed in this permanent form before the public could not have been undertaken by private enterprise. Their object is to furnish a basis on which exploration may go forward in search of petroleum in Sinai, guided by the stratigraphy of a difficult and arid region. The oil-indications occur in Upper Cretaceous strata, mainly in the Cenomanian series, and any local concentration that may be found will depend on these beds as the primary sources of supply. Two places where the conditions seem favourable have been recommended to the Egyptian Government as sites for boring (p. 142). The clean exposures of rock-edges allow the geologist to read the structure of this desert country, as he can among the splendid folds of the Lange Bergen or in the high plateaus of Arizona. The features of a rock-desert are admirably pictured in photograph No. 12, where something is seen of the most notable structural feature of the region, the Cretaceous beds being strongly folded as they are traced downwards, while the conformable Eocene above them is almost undisturbed. The dome-structure sought for by oil-prospectors is thus present in the areas where beds older than the Santonian are exposed, but is scarcely to be traced in higher series. The authors, after a useful historical review (p. 37), advise the abandonment of the term Nubian Sandstone as indicating a stratigraphical horizon.

A thin band of potassium salt has been found under Gebel Sinn Bisher, a place where old workings, probably for rock-salt, may be traced. We may note the spelling Gebel, for Jebel, now adopted in Egyptian memoirs, which will commend itself equally to English-speaking folk. We congratulate Messrs. Moon and Sadek on carrying out this fine piece of mapping in a country where "life is, at its best, a very hard one," and where the Arab natives speak, quite happily, of their "homes" in caves cut in the mountain sides.

G. A. J. C.

Our Bookshelf.

La Géographie de l'Histoire: Géographie de la Paix et de la Guerre sur Terre et sur Mer. Par Jean Brunhes et Camille Vallaux. Pp. xi+716. (Paris: Félix Alcan, 1921.) 40 frs. net.

Two distinguished French geographers have collaborated in producing a volume on the relations of geography and history, which is really a treatise on political geography. Rather more than half the volume is concerned with the principles of the subject, and the remainder with their application to current political and social problems, arising out of the redistribution of territory and alterations in frontiers after the war.

Beginning with the thesis that man is the chief geographical agent, since he can more effectively modify the surface of the earth than the physical agencies at work, the authors consider the distribution of man. Regions of dense population may be either zones of passive concentration where conditions favour increase in numbers but do not demand any great degree of effort, or zones of active concentration where man, reacting against conditions not wholly favourable, triumphs by the exercise of effort. In the first category are regions of high temperature with considerable atmospheric humidity and abundant surface water, like the Chinese river valleys or the Nile delta. In the second category are oceanic borderlands and islands in temperate regions where conditions entail some struggle against sea and climate but are not unpropitious. In this category also are the areas where temperate forest has to be cleared and where coalfields are exploited.

From these "facts of fixation" the authors pass to "facts of movement" and discuss the influences behind migration and human movements. Some of the most important chapters in the book are those which deal with the growth and stability of states and the positions favourable to sites of capital cities. In struggle, though not necessarily war, the authors see one of the essentials for the healthy life of a state. Struggle means growth, but a state of political and social equilibrium means stagnation and decay. We have no space to do justice to this volume, and have indicated only a few of the ideas it contains. Every step in the authors' arguments is abundantly illustrated by concrete examples. The only drawback to the book is its lack of lucidity in places. The style at times is more ponderous than one would expect from French writers. There are black and white maps and full indices.

Handbuch der Pflanzenanatomie. Herausgegeben von Prof. K. Linsbauer. Allgemeiner Teil: Cytologie (Die Organe der Zelle). Band 1., Zelle und Cytoplasma. Von H. Lundegårdh. Pp. 192. Band 2., Allgemeine Pflanzenkaryologie. Von Prof. Dr. G. Tischler. Pp. 384. (Berlin: Gebruder Borntraeger, 1921.) 2*l*. 5*s*.

THE volumes under notice are the first two in a series to be published under the general title "Handbuch der Pflanzenanatomie." The complete series as projected will number 15 or 20 volumes by various authors, under the general editorship of Prof. K. Linsbauer. It will include volumes on cytology, histology, galls, experimental anatomy, and a series on the "anatomy" of the various plant groups from Mycetozoa to flowering plants. Two volumes—both unfinished—have already been issued, the first, by Dr. H. Lundegårdh, dealing with the cell and cytoplasm; the second, by Prof. G. Tischler, giving a general account of the plant nucleus. The price quoted in English money for the two volumes, in paper covers, is unjustifiably high, and must mean a huge rate of profit for the publishers. The sale on these terms is not likely to be very wide.

The first volume begins with a history of plant anatomy and the cell theory, occupying 60 pages, and illustrated by figures from Hooke, Malpighi, N. Grew, and others. Then follows an account of cell structure and form, with numerous illustrations. The protoplasmic connexions between cells are considered at some length. Other topics considered are the arrangements of cells in tissues, and the physical and chemical organisation of the cell.

The second volume treats of the plant nucleus in considerable detail, beginning with the morphological and chemical organisation of the resting nucleus, and its relations to the cell as a whole. This part occupies 232 pages. The remainder of the volume, which is as yet incomplete, deals with nuclear division and its various forms in different plant groups. The numerous figures are taken from the cytological literature of the last thirty years.

Thirty-fifth Annual Report of the Bureau of American Ethnology to the Secretary of the Smithsonian Institution. 1913–1914. In 2 Parts. Part 2 Pp. viii + 795-1481. (Washington: Government Printing Office, 1921.)

THIS volume forms an important supplement to that which preceded it, giving a collection of bardic chronicles and songs illustrating the beliefs and customs of the Kwakiutl, a fishing-tribe on the coast of Vancouver Island. It has been compiled by Mr. G. Hunt, a member of the tribe, and the text is given in the tribal dialect with an English translation. It is not easy reading, but the report in the preceding volume supplies an adequate commentary. It forms an impressive picture of life in the lower culture. We have traces of totemism in the shape of paintings of animals on the sides of the house door and posts erected with special ceremonies. Much of the ritual consists of orgiastic dances, performed by men and women in a state of nudity, wearing masks, their faces being painted with charcoal, on which swan-down is stuck, their heads and necks adorned with pieces of red cedar. It also assumes a more brutal form. In one account we read: "The Rich-Woman carried in her arms a body, leading the Cannibal; and the Tamer went on the right-hand side of the Cannibal, and the One-Who-Presses-Down went on the left-hand side of the Cannibal, and each of the four eats part of the corpse—that is, the Cannibal and the Rich-Woman, and the Fire-Dancer and his Grizzly-Bear-of-The-Door." Scattered through the book are interesting accounts of the initiation of novices, the magical effect of names, magical songs sung to secure the capture of salmon, prenuptial incontinence, marriage by purchase and the levirate, burial in trees, magical transformation of men into animals, and much other matter of interest to anthropologists. It is well that these facts should have been recorded, as the tribe is rapidly coming under "civilised" influence. In one list of gifts we read of blankets, canoes, jewellery, forty sewing-machines, and twenty-five phonographs.

(1) *Lehrbuch der Elektrotechnik.* Von Dr. E. Blattner Erster Teil. Vierte Auflage. Pp. ix + 423. (Bern: K. J. Wyss Erben, 1922.) 20 fr.

(2) *Electricity.* By Sydney G. Starling. (Science in the Service of Man) Pp. viii + 245. (London: Longmans, Green and Co., 1922.) 10*s*. 6*d*. net.

(3) "*Lektrik*" *Lighting Connections.* With Introductory and Explanatory Notes by Gus. C. Lundberg and the late W. P. Maycock. Seventh Edition (Thoroughly Revised). Pp. 156. (London: A. P. Lundberg and Sons, 1921.) 1*s*. net.

(1) WE welcome the fourth edition of the first volume of Dr. Blattner's text-book. The principles of electrical engineering are very clearly stated and as the international symbols and nomenclature are adopted it can be readily understood even by a student whose knowledge of German is limited.

(2) Mr. Starling has written an interesting popular work on electricity. The subjects of the various chapters are well chosen, theory and practice being evenly balanced. The epoch-making discoveries of recent years in radio-telegraphy and in the theory of the atom are included.

(3) The third of the works under notice is a useful little book on electric wiring. It shows various ways of wiring electric lamps so that they can be controlled from several different places and also how the light they give can be varied. The special switches used for these purposes are described.

Early British Trackways, Moats, Mounds, Camps, and Sites. A Lecture given to the Woolhope Naturalists' Field Club, at Hereford, September 1921. By Alfred Watkins. Pp. 41 + 20 plates. (Hereford: The Watkins Meter Co; London: Simpkin, Marshall and Co., Ltd., 1922.) 4*s*. 6*d*. net.

IN this little book the author attempts to show that during a long period, going back at least to neolithic times, all trackways were in straight lines marked out by experts on a sighting system. Such sighting lines went from mountain peak to mountain peak with secondary sighting points on the lower ground. It is fairly obvious that long distance roads in primitive times would tend to lie in a more or less straight line between prominent peaks. This scarcely needs reiti-

fication, and Mr. Watkins' case must rest mainly on his intermediate points. These he finds in mounds, moats, tumps, churches (occupying the site of an earlier mark), stones, trees, and camps, holy wells, and the like. Place-names are also called in to support his argument. Without entering into a detailed examination of his evidence, which the reader may do with the aid of an ordnance map, it may be said generally that in some cases the so-called sighting marks were the objective of the road as in the case of a holy well or a ford, and that others, such as a burial mound or an encampment, owed their position to the previous existence of a road.

Poverty and its Vicious Circles. By Dr. Jamieson B. Hurry. Second and Enlarged Edition. Pp. xvi + 411. (London: J. and A. Churchill, 1921.) Price 15s. net.

THE first edition of this detailed study of poverty was published before the war. In this second and enlarged edition the general plan of the work remains unaltered, but the author has revised and extended the original chapters and has written several new ones. Further, he has viewed his subject more from the international standpoint. His "vicious circles" are the various elements entering into the causation and perpetuation of poverty which aggravate or intensify the causes out of which they grew by lowering the standard of life and efficiency. Dr. Hurry describes in detail the effect of such factors as defective housing, defective feeding, defective clothing, defective education, defective credit, unemployment, insecurity, and the like. Each is considered separately, it being a part of the author's theory that each factor must be diagnosed and attacked in isolation; but the interaction of the circles one with another is both recognised and considered. The last portion of the book deals with remedial measures and gives a useful historical survey of poor relief under the State and by local authorities, and of the scope and objects of a number of private or semi-public voluntary organisations.

Plant Materials of Decorative Gardening: The Woody Plants. By Prof. Wm. Trelease. Second Edition, Revised. Pp xliii + 177. (Urbana, Ill.: The Author, University of Illinois, 1921.) 1 dollar.

BY the help of this handy little volume a careful observer, who will make himself acquainted with the technical terms as explained in the glossary at the end of the book, may learn the name of any hardy tree, shrub, or woody climber that he is likely to find cultivated in the eastern United States—apart from the extreme south—or in northern Europe, except on the more pretentious estates, or in nurseries or botanical establishments. It accounts for 1150 distinct kinds, representing 247 genera and 782 species. For a few hopelessly complicated genera, such as haws, cotoneasters, and roses, only the most easily recognised species have been admitted. By means of a dichotomous key, divided into four sections—trees, bushes, undershrubs or bog or rockery plants, and woody climbers or scramblers—the name of the genus may be determined. The greater part of the book is occupied by a systematic description of the genera under their families, and under each genus is given a key to the species.

Common Plants. By Dr. M. Skene. (Common Things Series.) Pp. 271 + 26 plates. (London: Andrew Melrose, n.d.) 6s. net.

DR. MACGREGOR SKENE has produced a very readable series of essays, written in thirty-three chapters around different common plants, which are made the texts for a popular presentation of many of the problems and achievements of the modern study of plants. In the opening sections the themes of plant nutrition and the world's food supply are grouped around the wheat plant. Other chapters treat, for the popular reader, the various groups of plants, while still others are concerned with the rise of a land flora and various problems of the inter-relations of plants and animals, water supply, reproduction, and the relations of plants to man. The paper is unfortunately of poor quality, but the essays are excellently informed and attractively written, with lucid style and a human point of view.

Scientific Management in the Home: Household Engineering. By Mrs. Christine Frederick. (Efficiency Books.) Pp. 527. (London: George Routledge and Sons, Ltd., 1920.) Price 12s. 6d. net.

THERE is no place where the application of science is more desirable than in the home, and none where it is more commonly neglected. Mrs. Frederick, whose work is already known in this country through her connexion with *The Ladies' Home Journal*, here presents the story of her success in managing her own home. Science is to be found pleasantly blended with common sense in the pages of this book, which is to be recommended to the notice of private individuals as well as to those who are concerned with the teaching of domestic economy.

Précis de physiologie végétale. Par Prof. L. Maquenne. (Collection Payot.) Pp. 175. (Paris: Payot et Cie, 1922.) 4 frs.

THE author of this little book is a professor at the Museum d'Histoire naturelle in Paris, and here reproduces in simple, lucid, and attractive form the substance of a course of lectures given at the Museum for more than twenty years. The subjects briefly treated include osmosis, colloids, germination, growth, assimilation, respiration, etc. The definition of such terms as osmosis and colloid are not above criticism, but any one with no previous knowledge of the subject should find it an attractive and, on the whole, an accurate presentation of the general features of plant physiology.

Dictionary of Botanical Equivalents: French-English, German-English. By Dr. E. Artschwager and E. M. Smiley. Pp. 137. (Baltimore, Md.: Williams and Wilkins Co., 1921.) n.p.

THIS little dictionary of botanical terms should prove useful, especially for students. It is nearly all German, only 15 pages being devoted to the French-English portion. The pages are interleaved, so that additional terms can be entered at any time. The explanations given are not always happily chosen or accurate. Thus *zeitlicher Dimorphismus* is rendered "polymorphy."

Letters to the Editor.

The Mode of Feeding of the Jelly-fish, *Aurelia aurita*, on the Smaller Organisms in the Plankton.

WHILE engaged in investigations (carried out with the aid of a Government grant) on the oyster beds in the River Blackwater, a jelly-fish (about 8 cms. in diameter) kept as a pet was given large numbers of oyster larvæ to see what it would do with them. From the fate of the oyster larvæ it was at once seen that the adult jelly-fish, *Aurelia aurita*, feeds definitely and—normally—automatically on smaller plankton organisms in a manner resembling that in which bivalves, some worms, and other animals feed on plankton. On adding the oyster larvæ to the jar in which the jelly-fish was living, it was observed that the larvæ were quickly formed up on the ex-umbrella surface of the jelly-fish in lines embedded in mucus and were also swept on to and retained in quantity on the oral arms. This immediately raised suspicion, and the jelly-fish was thereupon fed at intervals and carefully observed [1]. It was found that small plankton organisms of about the size of oyster larvæ were collected from the ex-umbrella surface of the jelly-fish and carried, mainly by ciliary action, towards the rim of the umbrella. The rhythmic waves of contraction of the bell or umbrella assist in carrying the strings of collected plankton-food to the edge of the umbrella, whence they are transferred—by a process not yet fully worked out—either to the oral arms or to the under surface of the rim of the umbrella. At the rim of the umbrella in this jelly-fish there is narrow curtain fringe cut normally into 8 segments so that one portion of the fringe lies between two of the marginal sense-organs (tentaculocysts). The fringe therefore resembles that often seen at the rim of a parasol except that it consists normally of 8 segments. The tentacles arise from the edge of the umbrella at the base of and outside this fringe.

It has thus been seen that by some means—partly by ciliary action and partly by contraction of the bell—a portion or all of the plankton collected on the ex-umbrella surface of the jelly-fish is transferred to the inner or outer sides of these umbrella fringes. Food-particles consisting of the smaller plankton organisms are, however, also collected on the inner surface of the umbrella and apparently also on the bases of the rim tentacles and transported in mucus by ciliary action to the inner side of the fringe at the edge of the umbrella. Plankton is therefore collected by both ex- and sub-umbrella surfaces and probably also on the bases of the rim tentacles and transported thence to the rim fringe. When the plankton reaches the rim fringe it is carried by ciliary action along the base to the *middle* of each segment of the rim fringe. Thus when an Aurelia has been feeding there are normally 8 blobs of food collected in the middle portions of the 8 rim fringes, which lie exactly opposite the straight adradial canals. It is curious that the point at which the blobs of food are constantly collected is not specially differentiated in any way unless it be by the development of an extra pucker in the rim fringe, which permits the accommodation of the food-mass. As and when the blobs of food are collected, it can be observed that the jelly-fish deliberately and apparently consciously licks them off by passing over each the separated lips of an oral arm. The cilia on the internal faces of the arm quickly take charge of the food-mass and pass it into the groove made by the infolding of the sides of the oral arm. From the groove in the oral arm the food can be seen to be carried towards the mouth proper and travel by its own channel into the appropriate gastric pouch to be digested. When an Aurelia is actually feeding, food can be seen to be passing into the gastric pouches by four main channels. Oyster larvæ dropped on to the central region of the arms near the mouth appeared to be greedily accepted, and within a few minutes had passed into the gastral pouches by ciliary action through one or other of the four main food-channels. There are, however, two subsidiary food-channels to each gastric pouch, so that on occasions three strings of food can be seen passing into one gastric pouch.

After noticing the way in which this jelly-fish feeds it was realised that the kind of plankton in the sea at a particular moment could be speedily found out by capturing individuals and extracting and examining the collected food-masses from what may now be called the food-pouches on the rim of the umbrella opposite the straight adradial canal. Fortunately it was a simple matter to catch specimens of Aurelia recently washed into the oyster pits at high tide. Examination of such food-masses taken direct from the Aurelia showed them to consist of the following planktonic organisms: gastropod larvæ, of Crepidula and others, oyster larvæ (black spat), copepods, various species including Calanus and Harpacticids, Epicaridian larvæ in fair quantity, larvæ of cirripedes and copepods, Cypris larvæ of balanoids, young polychætes, especially Polydora, a good number of rotifers, algal threads green and brown, in one case with a large colony of vorticellids attached, eggs of polychætes or rotifers, eggs and tadpoles of Ciona and other ascidians, nematode worms, tintinnoids, a number of diatoms of several species, and some sand grains. In one instance an Aurelia was liberated for a few minutes in an oyster pit, which contained what was practically a good natural culture of the diatom Nitzschia. On examining the food-masses extracted from the food-pouches of this particular jelly-fish a few minutes after immersion in the water, fairly large numbers of the diatoms were found embedded in the mucoid food-mass.

It is clear, therefore, that Aurelia feeds mainly on what is technically termed medium to coarse plankton, but that it also captures small quantities of the finer plankton. In addition it is well known that larger organisms are taken and eaten, but from the above description it would seem that in the normal habitat of this jelly-fish, plankton organisms of the smaller kind will constitute the main diet.

From the relatively slight morphological variations which occur in the group to which Aurelia belongs, it would seem highly probable that a similar but probably modified mode of feeding occurs throughout the group. In some members of the group it is well known that young fishes frequently take shelter under the umbrella and often inside the cavities of the jelly-fish with impunity, but hitherto it has been difficult even to guess at a reasonable explanation of the association of a jelly-fish with—what has often been considered legitimate prey—young fishes. The mode of feeding in Aurelia, however, suggests a possible explanation of this phenomenon if, as is very likely, other allied jelly-fishes feed in a similar way. The aggregation of plankton-food in masses provides an excellent opportunity for parasites has-

[1] Gemmill (Proc Roy. Phys. Soc. Edin , vol xx part 5, 1921) records some interesting notes on food-capture and ciliation in the ephyra of the jelly-fish, which are not, however, the same as in the adult, the structure of which is more complex.

is seen in the case of the pea-crab and various bivalve molluscs and ascidians, or Myzostoma and Antedon. Now many jelly-fishes are infested with amphipods such as Hyperia, and it is a reasonable deduction that these crustaceans may be feeding on the food material collected by the jelly-fish. Thus, if the young fishes which take shelter below the umbrella of a jelly-fish assist the jelly-fish by keeping down ecto-parasites such as Hyperia, then an intelligible explanation is offered of the association of young fishes with such an apparently voracious host as a large jelly-fish, for in return the jelly-fish in these circumstances would have less of its own food stolen. Roche's Limits for Satellites.

THE notice in NATURE (July 15, p. 89) respecting Dr. Fountain's work on Roche's limit for satellites brings to my recollection some estimates which I made many years ago with respect to the stability of satellites moving close to the surface of Mars (Trans. Roy Dub. Soc., 1897, vol vi.)

The question arose in connexion with a theory accounting for the "canals" as resulting from stresses set up in the surface rocks of Mars by the proximity of such satellites. The doubling of the canals came out nicely and the curvature of the canals as mapped by Lowell, Douglass, and Pickering was in agreement But the doubt arose as to whether former satellites of sufficient magnitude could have preserved their stability when circulating around the planet with the requisite degree of approximation

Assuming that the satellite possessed the cohesive strength of basalt and taking the case of Phobos supposed to be moving in an orbit but 23 miles from the planet's surface (*i e.* with but five miles separating the surfaces of planet and satellite), I found that the satellite, even at this distance, would be stressed only to one-seventh of its breaking strength.

Optical Definition and Resolving Power.

IN Mr Mallock's letter on "Definition, Resolving Power and Accuracy," published in NATURE of May 27 (vol 109, p 678), reference is made to the measurement of star images on eclipse plates, from which one might infer that the evidence for the Einstein deflexion of light obtained in 1919 was of a very doubtful character.

I have had no experience in measuring star images, but there is little doubt that if the same order of accuracy can be obtained as is possible in measuring spectrum lines, the Einstein deflexion should be easily determinable with a focal length of 19 feet, provided that it can be disentangled satisfactorily from the scale correction

In my method of measuring photographs of spectra the image of a line is not bisected by a thread, but a positive copy is superposed on the negative in the micrometer and the coincidence of the two images estimated. By this means the intervals to be measured are doubled, and an extraordinary degree of precision is attainable with practice, as is shown by the agreement between different measurers I have often had occasion to repeat measures made by one of my assistants of the shifts of the solar lines with reference to the arc lines, and we rarely differ by an amount exceeding 0·001 mm. in the interval measured. This is the result of taking the means of six settings in each line, and the probable error derived from the accordance of settings is usually about half a micron.

Probably star images cannot be measured so accurately as this by the ordinary method of bisection, but a skilled measurer should be able to determine the position of a star easily within 0·005 mm. or, on the scale of the eclipse plates, within 0″ 18.

Interspecific Sterility.

DR. BATESON in his letter on interspecific sterility (NATURE, July 15, p 76) seems to lay insufficient emphasis on certain facts If one considers plant and animal species in general, it would appear that interspecific sterility is by no means so general as was formerly assumed to be the case Among the Œnotheras, in which great numbers of species crosses have been made, complete fertility, in the sense that large numbers of fertile offspring are produced, is the rule unless the forms differ in chromosome number. Even species of Œnothera which come from widely separated regions and differ conspicuously in all their characters, including flower-size, are fertile in crosses That a certain amount of gametic and zygotic sterility also frequently occurs is of course well known, and it is probably correctly interpreted in terms of lethal factors. But lethal factors are not peculiar to wild species, for numbers of them arise in the mutations of *Drosophila melanogaster*.

Among animals, interspecific sterility appears to be more widespread, but even here the Bovidæ are, I believe, all interfertile The contrasted condition of the Equidæ, at least as regards the horse and the ass, is accounted for by the difference in their chromosome numbers. In the Drosophilidæ, where interspecific sterility is extreme, there is a considerable range in chromosome form and number. The two species, *Drosophila melanogaster* and *D simulans*, which are extremely alike and have similar chromosome groups yet produce sterile hybrids, might be cited as corresponding exactly to Dr Bateson's conception of interspecific sterility But it is an extreme case, and there are probably more numerous instances to cite on the other side

Dr Bateson refers to the case of *Œnothera gigas* and agrees that tetraploids frequently do not breed freely with diploids But he says that "the applicability of that example is exceedingly doubtful" because we "can scarcely regard an unresolved pair of twins, such as the tetraploid must be, as a specifically distinct organism." It is this statement in particular to which I should be inclined for several reasons to take exception. In the first place, in calling the tetraploid an "unresolved pair of twins" Dr. Bateson scarcely recognises the intimate character of the union involved I formerly analysed (*Arch f. Zellforsch* vol 3, pp 525-552, 1909) the changes which have occurred in *Œ gigas* in so far as this could be done by comparative cell measurements, and found that the cell units were not merely larger, owing to the doubling in the chromosome content of their nuclei, but that in various tissues they were altered in shape, the increase in one dimension having been much greater than in another. Moreover, the genetic behaviour of *Œ gigas* indicates, as de Vries first contended, that some other change has taken place in the germplasm of this species, in addition to the doubling of the chromosomes.

I have only recently been convinced on this point by comparisons of *Œ. gigas* with the tetraploid forms obtained by Winkler (*Zeits. f. Botanik*, 8,

417-531, 1916), from his grafting experiments with the tomato. Here the tetraploid form apparently arises through the fusion of pairs of somatic nuclei where the cut surfaces of the cells are in contact. The forms obtained in this way appear to be merely tetraploid, stouter but without any alteration in the shape of leaves or other organs such as occurs in *Œ. gigas*. Winkler shows that these tetraploids have larger cells, nuclei and chloroplasts, but there are apparently no changes in cell shape except in the pollen grains, which have four pores instead of three just as in *Œ. gigas*. There seems no reason to alter my original interpretation of this change in the pollen grain as a direct result of the altered space relationships between the larger cell and its nucleus in the tetraploid forms.

It therefore appears probable that in some experimental tetraploid forms, such as Winkler's Solanums and probably the Marchals' tetraploid mosses, all the changes are such as follow directly from the original doubling of the chromosomes, while in others such as *Œ. gigas* and certain wild tetraploid species, an additional change has taken place in the germplasm. One cannot yet, however, regard this as fully proven.

It might also be pointed out here that the wide occurrence and evolutionary significance of tetraploid species in nature has not yet been generally realised by biologists. In Potentilla, for example, a whole group of wild species is tetraploid as compared with others. Species with $4X$ chromosomes are also known to occur in many other genera, such as Lactuca, Crepis, Muscari, Acer, etc. Such a doubling of the chromosome number must have occurred in connexion with the origin of many wild species and genera.

Tetraploidy undoubtedly forms a barrier to free crossing with diploid forms in any line of descent. I therefore see no reason why such forms as *Œ. gigas* arising in cultures should not be regarded as mutations significantly accompanied by partial interspecific sterility. For both in cultures and in Nature the cross-breds with unbalanced chromosome groups tend to be eliminated, leaving the pure forms each to perpetuate itself.

The Influence of Science.

In his letter to Nature (July 15, p. 78) Sir George Greenhill does well in directing attention to the fact that the quarrel between Galileo and the Holy Office was largely a domestic quarrel between two opposing schools of thought. It is historically a fallacy, though a very common one, to suppose that the freedom of experimental inquiry was secured in consequence of the action of the Roman Curia in the case of Galileo. So long as scientific investigators confined themselves to their own legitimate subjects of study, and left doctrinal and Scriptural matters alone, freedom of experimental inquiry was never interfered with by ecclesiastical authority. Nicholas Copernicus was a devout Catholic priest, and his heliocentric doctrine was freely taught, even in ecclesiastical colleges, until Galileo interested himself as a champion of the system.

For Galileo, as all historians testify, was a truculent and hot-headed controversialist, who, in spite of the advice of his friends not to raise the question (I quote from his contemporary Guicciardini, the Tuscan ambassador), "demanded that the Pope and the Holy Office should declare the Copernican system to be founded on the Bible; he wrote memorial after memorial. Paul V., wearied with his importunities, decreed that the controversy should be determined in a Congregation, and having sent for Cardinal Bellarmine, ordered him to bring it immediately before the Holy Office." Let me make use of an analogy from the practice of our own English Courts to elucidate the matter. The Court of King's Bench was originally constituted to judge cases pertaining to the King's peace. To widen its jurisdiction, all classes of injuries, even actions for breach of contract, had to be interpreted as acts of violence, even though perpetrated by otherwise peaceful citizens.

Similarly, the Holy Office had, by its procedure, to consider every case submitted to it, with reference to heresy and orthodoxy. Let us also bear in mind that Holy Scripture must ordinarily be interpreted literally, unless a rigid proof can be adduced to the contrary. What rigid proofs, in the then state of scientific knowledge, could Galileo allege in support of his contention that the Copernican system was founded on the Bible? Let us recall in passing that such eminent men of science as Tycho-Brahe and Bacon rejected the system, while Descartes would not admit the hypothesis as proved, and that the Cardinals of the Congregation, so far as proofs of Copernicanism were concerned, had perforce to rely upon the opinion of their scientific advisers. The only proofs that were brought forward were the analogy of Jupiter's satellites, the moon-like phases of Venus, and the simplicity with which the theory accounted for the observed motions of the planets. The other alleged proofs from the tides and the earth's magnetism were worthless.

On the other side was the apparent authority of the words of Scripture, the universal experience of mankind, which seemed to attest that the earth was immovable, while the sun, moon, and stars moved round it, and the Ptolemaic system which for centuries had explained in a satisfactory manner the apparent movements of the planets. In such circumstances what could the Congregation do but declare, according to the forms of the court, that the Copernican system was heretical, in the sense that it contravened the literal and obvious meaning of Scripture? According to the knowledge of that time, the Copernican system was "false and absurd philosophically, inasmuch as it expressly contradicts the doctrine of Holy Scripture." The proviso and restriction is noticeable.

What did Galileo do? Instead of teaching the Copernican theory as a scientific hypothesis, after a most generous reception in Rome in 1624 by his friend Pope Urban VIII., he returned to Florence, and in his famous Dialogue not only lampooned his benefactor, but was guilty of gross contempt of court. For such egregious contempt of court an English judge would rightly commit a man to prison. Galileo had as a penance to recite certain prayers, and was sent to a beautiful villa at Arcetri, where, free from the disturbing influences of controversy, he was at liberty to pursue his favourite studies.

As Whewell says in his "History of the Inductive Sciences," pp. 425-6, "The persecutors of Galileo are still held up to the scorn and aversion of mankind; although, as we have seen, they did not act until it seemed that their position compelled them to do so, and then proceeded with all the gentleness and moderation which were compatible with judicial forms." Or, to quote another non-Catholic, Prof. A. De Morgan (English Cyclopædia, "Motion of the Earth"), "We heartily wish all persecutions, Catholic and Protestant, had been as honest and as mild." Nor did the Roman Curia possess a monopoly in opposition to Copernicanism. Martin Luther went further, for he considered Copernicus to be an arrogant fool, who wrote in defiance of Scripture, while Melancthon declared

that such mischievous doctrines should be suppressed by the secular arm.

Finally, is it not time that this old bogy of the case of Galileo, as a proof that the Church was opposed to scientific research, should be decently buried? "The Papal power," wrote De Morgan (*loc. cit.*), "must on the whole have been moderately used in matters of philosophy, if we may judge by the great stress laid on this one case of Galileo." Cardinal Newman dubbed it rightly as "the one stock argument." A. L. CORTIE, *S.J.*

Stonyhurst College Observatory, Lancs.

Surface Tension and Cell-Division.

IN a recent paper on "Surface Tension and Cell-Division" (Q.J.M.S. 66, pp. 235-245), Mr. J. Gray maintains that "cell-division may be accounted for by the movement of the two asters away from each other," and that "there is no necessity to postulate regions of differential surface tension at the poles or equator of the cell."

These conclusions are drawn chiefly from the results of a series of experiments in which the effect of "acid" sea-water on the cleaving eggs of *Echinus miliaris* is interpreted in the light of the effect of increased hydrogen-ion concentration on an oil-water interface. Mr. Gray points out that there is undoubtedly a lipoid or oily phase in the protoplasmic surface, but, if any value is to be placed on the analogy between the effect of acid on cleaving eggs and on an oil-water surface, one has to suppose that the lipoid phase in the protoplasmic surface is a continuous phase, otherwise two different types of surface are being dealt with. This view, as pointed out by Bayliss (2nd Brit. Assoc. Rep. Colloids, 1918), would necessitate that the volume of the cell should not have any definite relation to the osmotic pressure of the external solution.

In these experiments it was shown that if the egg, in which a cleavage furrow had appeared, is placed in "acid" sea-water, the furrow disappears and, owing to the unknown force which elongates the egg, equilibrium is attained when the egg has the form of a cylinder with hemispherical ends. The shape of the dividing egg is stated to be dependent entirely on (*a*) the surface tension at the egg surface, and (*b*) the other force acting against the surface tension which produces elongation of the cell axis and is "associated in some way with the elongation of the astral figure." Now the pressure inside the fluid egg at any region due to surface tension can be determined from the curvature of the egg surface in that region. Since the egg is presumed to be in equilibrium at any stage during mitosis, any inequalities in pressure due to the surface tension and resulting from the varying curvature, must be counteracted by the second "elongating" force. In the case quoted above, in which the dividing egg is in equilibrium when its shape is that of a cylinder with hemispherical ends, it is easy to show that the pressure inside the hemispherical caps due to surface tension is exactly twice the pressure inside the cylindrical portion due to surface tension. Thus the elongating force, of which the astral figure is to some degree an expression, must produce a differential pressure on the inside of the egg surface, such that the pressure exerted over the middle cylindrical portion is uniform and equal to half the pressure produced over the hemispherical ends. If the view is accepted that the mitotic figure is in any way connected with the force that produces elongation and cleavage of the egg, I think the hypothesis that this force is essentially a polar force must be adopted, and it is difficult to see how any polar force could produce such a distribution of forces as is necessitated to produce equilibrium in the fluid cylindrical egg described by Mr. Gray.

He further describes an experiment as due to Plateau, on a drop of oil placed between two metal rings "so as to form a complete cylinder" (of course, with spherical end surfaces), which, on moving the two rings apart, changed in form, when the distance between the rings became greater than ⅔ the diameter of the rings, in the same way as a dividing egg. The exact reference to this experiment is not given, but the experiment is very similar to one that Plateau carried out on the stability of a fluid catenoidal surface. According to Mr. Gray a cleaving egg can be divided into three parts: a middle cylindrical portion and two convex ends to this cylinder. The middle cylinder is taken to be analogous to the drop of oil in Plateau's experiment. It is obvious, however, that the whole of this experiment depends on the fact that the two rings, as they are being moved apart, exert a lateral thrust on the surface film of the drop. Is one, then, to believe that the force which causes the egg to elongate also exerts a lateral thrust in two parallel planes corresponding to the two rings? Actually, if there is sufficient oil between the two rings they may be moved apart to a distance equal to π times the diameter of the rings before the central cylindrical portion becomes unstable and divides, but this in no way resembles the form of any cleaving egg, so far as I am aware.

While I quite agree with Mr. Gray that the mitotic force counteracts the effects due to surface tension, it seems to me that one cannot account for the stability of his cylindrical stage on the supposition of uniform surface tension over the whole egg surface, without ascribing to that mitotic force properties that one would hesitate to ascribe to forces focussed round two definite centres. Unless the view that the forces which elongate the egg are correlated with the spatial relations of the two centrosomes is adopted, all the morphological evidence of the mechanism of cell-division is neglected.

In the introduction to his paper Mr. Gray says that theories postulating a higher or lower surface tension at the equator of a cleaving cell are of little value, as "there is no apparent means of determining how such a state of affairs could arise." In many cells it has been shown that the cytoplasmic inclusions are arranged around the centrosomes as foci, and further, that the distribution of these elements may be correlated with the apparent activity of the centrosomes. From this it may be inferred that there are substances in the egg which are repelled or attracted, either directly or indirectly, by the centrosomes. One of the first events in the cleavage of an Echinus egg is the appearance of two "active" centrosomes. These are approximately symmetrically placed in the egg and move apart from one another. Substances repelled by the centrosomes will tend to gather at the surface of the egg, but, as the centrosomes move apart, these bodies, once having reached the surface, will move towards that region of the egg surface in the plane in between the two centrosomes, which is termed the equator of the egg. If the presence of these substances in the surface film of the egg affects in any way the surface tension of the protoplasmic surface, here is a mechanism whereby there may arise a differential surface tension over the surface of the cleaving egg. Electricity and Matter.[1]

By Sir Ernest Rutherford, F.R.S.

It has been customary in the earlier Kelvin lectures to give an account of some phase of Kelvin's work. I could easily follow this custom by concentrating on the publications of Kelvin that deal with the proof of the atomic nature of matter and the dimensions of atoms and molecules, including the first suggestions of the mechanism of atomic constitution. This was a subject in which Kelvin was permanently interested. In his Royal Institution lecture of 1883, reprinted in "Popular Lectures and Addresses," vol. 1, he gives an illuminating account of the different lines of evidence that all converge to a cumulative proof that matter is coarse-grained or atomic in structure and set a definite minimum limit to the dimensions of the atom. His deduction of the diameter of the water molecule from the cooling effect observed when a water film is stretched, is one of the most notable of these examples. In his later papers he accepts Stoney's arguments in support of the atomic nature of electricity, and in a paper of curious title, "Æpinus Atomised,"[2] he restates the old theory of Æpinus of the nature and relation of positive and negative electricity in a more modern form, by assuming that the negative electricity in an atom is distributed in the form of definite units called "electrions"—or electrons, as we should now term them—held in equilibrium embedded in a sphere of uniform positive electrification. This was the first type of model atom put forward. A similar type of atom, developed and worked out in detail by Sir J. J. Thomson, played a notable part in giving a concrete view of atomic structure which was directly amenable to mathematical calculation. In some of his later papers, Kelvin devised types of atoms which, under certain disturbances, broke up with explosive violence, simulating in behaviour the atoms of radium. While keenly interested in such speculations, there remained the curious anomaly that he did not accept entirely the current explanation that radio-activity was a consequence of the successive disintegrations of atoms.

The discovery in 1897 of the individual existence of the negative electron of small mass, and the proof that it was a component of all the atoms of matter, was an event of extraordinary significance to science, not only for the light which it threw on the nature of electricity, but also for the promise it gave of methods of direct attack on the problem of the structure of the atom. This discovery of the electron, coupled with the recognition of the atomic nature of electricity, has created a veritable revolution in our ideas of atoms.

The first definite proof of the close relations that exist between electricity and matter we owe to the famous experiments of Faraday on the passage of electricity through electrolytes. It was clear that the simple numerical relations found by him between the electrochemical equivalents of the elements and their atomic weights could be simply interpreted by assuming that electricity was atomic in character and that the charges carried by the individual ions were integral multiples of a fundamental unit of charge. It is curious to note the long interval that elapsed before the idea of the atomic nature of electricity was generally accepted by men of science—possibly because of the great difficulty of obtaining confirmatory evidence. The suggestion was mentioned by Maxwell and Helmholtz, although with reservation, but was revived with conviction by Johnstone Stoney, who suggested that the name "electron" should be applied to the fundamental unit of electricity and made a rough estimate of its magnitude. Actually, as we know, the term "electron" is now used to denote not the actual value of the unit of charge, but the free atom of negative electricity.

Following the discovery of the independent existence of the electron and the proof of the production of charged ions in gases by X-rays and other radiations, it was implicitly assumed by men of science that electricity must be atomic in nature, and all the experimental data were interpreted on this view. It was found by Townsend that the charge carried by the ions produced in gases and by the electron itself was numerically equal to that carried by the hydrogen ion in the electrolysis of water, which was taken as the fundamental unit. By the ingenious device of balancing the weight of a charged drop by the attraction of the electric field, Millikan was able to give a very direct and convincing proof of the correctness of this view and to determine the magnitude of the fundamental unit with great precision. Knowing the value of this constant, the electrochemical data give us immediately the mass of the atom of each of the elements. While no one now doubts the atomic nature both of matter and of electricity, it should be noted that the atomic nature of matter is in reality a consequence of the discrete nature of electricity, for all the evidence indicates that the atom itself is a purely electrical structure.

. . . .

It was soon recognised that the negative electron of small mass was an actual disembodied atom of electricity, and that its apparent mass was electrical in origin. Sir J. J. Thomson had shown as early as 1881 that a charged body in motion behaved as if it had an additional electric mass due to its motion. The moving charge generates a magnetic field in the space surrounding it, resulting in an increase of energy of the moving system which is equivalent to the effect produced by an increase of the mass of the body. The experiments of Kaufmann and others on the swift electrons ejected from radium showed that the mass of the electron, while sensibly constant for slow fields, increased rapidly as the velocity of the electron approached that of light. This variation of mass was in good agreement with calculations based on the electrical theory. Later, Einstein from considerations of relativity showed that for any material particle, whether charged or not, the mass m must vary with speed according to the relation $m/m_0 = (1-\beta^2)^{-\frac{1}{2}}$, where m_0 is the mass for low speeds, and β is the ratio of the velocity of the particle to the velocity of light. Experimental results agree closely with this calculation.

Since there must always be electric mass associated with the movement of electric charges, it is natural

[1] From the thirteenth Kelvin lecture, delivered before the Institution of Electrical Engineers on May 18.

[2] Philosophical Magazine, March 1902.

to suppose that the mass of the electron is entirely electrical in origin, and no advantage is gained by supposing that any other type of mass exists. If the atom is a purely electrical structure, the mass of the atom itself must be due to the resultant of the electric mass of the charged particles which make up its structure. We shall see that only a small fraction of the mass of an atom can be ascribed to the negative electrons contained in it, but the main part is to be ascribed to the positively charged units of its structure. One of the main difficulties in our attack on the question of atomic constitution has lain in the uncertainty of the nature of positive electricity. Without entering upon the changes in point of view on this important question, it may suffice to say that the evidence as a whole supports the idea that the nucleus of the hydrogen atom, *i.e.* a positively charged atom of hydrogen, is the positive electron. No evidence has been obtained of the existence of a positively charged unit of mass less than that of the hydrogen nucleus, either in vacuum tubes or in the transformation of the radioactive atoms, where the processes occurring are very fundamental in character.

It might *a priori* have been anticipated that the positive electron should be the counterpart of the negative electron and have the same small mass. There is, however, not the slightest evidence of the existence of such a counterpart. On the views outlined, the positive and negative electrons both consist of the fundamental unit of charge, but the mass of the positive is about 1800 times that of the negative. This difference in the mass of the two electrons seems a fundamental fact of nature and, indeed, is essential for the existence of atoms as we know them. The unsymmetrical distribution of positive and negative electricity that is characteristic for all atoms is a consequence of this wide difference in the mass of the ultimate electrons which compose their structure. No explanation can be offered at the moment why such a difference should exist between positive and negative electricity.

Since it may be argued that a positive unit of electricity associated with a much smaller mass than the hydrogen nucleus may yet be discovered, it may be desirable not to prejudge the question by calling the hydrogen nucleus the positive electron. For this reason, and also for brevity, it has been proposed that the name "proton" should be given to the unit of positive electricity associated in the free state with a mass about that of the hydrogen nucleus, namely, about 1·007 in terms of O = 16. A name for this unit will be found very convenient in discussing the inner structure of atoms. In the following, the term "electron" will be applied only to the well-known negative unit of electricity of small mass.

On the classical electrical theory, the mass of the electron can be accounted for by supposing that the negative electricity is distributed on a spherical surface of radius about 1×10^{-13} cm. This is merely an estimate, but probably gives the right order of magnitude of the dimensions, though it should be pointed out that in some recent theories of Compton and others it has been supposed that the electron behaves like a flexible ring, the dimensions of which are about 10^{-11} cm., or about 100 times the original estimate. Without going into these difficult questions, what little experimental evidence there is seems to me to support the older estimate of size. Taking the view based on the older theory, the greater mass of the proton is to be explained by supposing that the distribution of electricity is much more concentrated for the proton than for the electron. Supposing the shape spherical, the radius of the proton should be only $\frac{1}{1800}$ of that of the electron. If this be so, the proton has the smallest dimensions of any particle known to us. It is admittedly very difficult to give any convincing proof in support of this contention, but at the same time there is no evidence against it. From the point of view of simplicity of explanation, it is natural to make the assumption that the proton and the electron are the fundamental units of which all atoms are built.

It would take too long to consider in any detail the gradual development in the last twenty years of our ideas on the structure of atoms. Progress has depended mainly on a clearer understanding of the relative part played by positive and negative electricity in atomic structure. It is now generally accepted that the atom is an electrical system and that the atoms of all the elements have a similar type of structure.

The nuclear theory of atomic constitution has been found to be of extraordinary value in offering an explanation of the fundamental facts that have come to light, and is now generally employed in all detailed theories of atomic constitution. At the centre of each atom is a massive positively charged nucleus of dimensions minute compared with the diameter of the atom. This nucleus is surrounded by a distribution of negative electrons which extend to a distance, and occupy rather than fill a region of diameter about 2×10^{-8} cm. Apart from the mass of the atom, which resides mainly in the nucleus, the number and distribution of the outer electrons, on which the ordinary physical and chemical properties of the atom depend, are controlled by the magnitude of the nuclear charge. The position and motions of the external electrons are only slightly affected by the mass of the nucleus. According to this view of the atom, the problem of its constitution naturally falls into two parts—first, the distribution and mode of motion of the outer electrons, and secondly, the structure of the nucleus and the magnitude of the resultant positive charge carried by it. In a neutral atom the number of external electrons is obviously equal in number to the units of positive (resultant) charge on the nucleus.

The general conception of the nuclear atom arose from the need of explanation of the very large deflections experienced by swift α- and β-particles in passing through the atoms of matter. A study of the number of α-particles scattered through different angles showed that there must be a very intense electric field within the atom, and gave us a method of estimating the magnitude of the charge on the nucleus. Similarly the scattering of X-rays by the outer electrons provided us with an estimate of the number of these electrons in the atom, and the two methods gave concordant values. The next great advance we owe to the experiments of Moseley on the X-ray spectra of the elements. He showed that his experiments received a simple explanation if the nuclear charge varied by one unit in passing from one atom to the next. In addition,

it was deduced that the actual magnitude of the nuclear charge of an atom in fundamental units is equal to the atomic or ordinal number when the elements were arranged in order of increasing atomic weight. On this view, the nuclear charge of hydrogen is 1, of helium 2, lithium 3, and so on up to the heaviest element uranium, of charge 92. It has been found that between these limits, with few exceptions, all nuclear charges are represented by known elements.

This relation, found by Moseley, between the atoms of the elements is of unexpected simplicity and of extraordinary interest. The properties of an atom are defined by a whole number which varies by unity in passing from one atom to the next. This number not only represents the ordinal number of the elements, but also the magnitude of the charge of the nucleus and the number of outer electrons. It could scarcely have been anticipated that, possibly with few exceptions, all nuclear charges between 1 and 92 would represent elements found on the earth. With the exception of the radio-active elements, the atoms are all stable for intervals represented by millions of years. The atomic weight of an element is not nearly so fundamental a property of the atom as its nuclear charge, for its weight depends upon the inner structure of the nucleus, which may be different for atoms of the same nuclear charge.

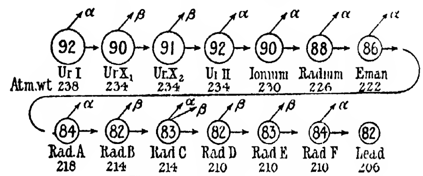
. . . .

The most definite information we have of the structure of the nucleus has been obtained from a study of the modes of disintegration of the radio-active atoms. In the great majority of cases the atoms break up with the expulsion of a single α-particle which represents the doubly charged nucleus of the helium atom; in other cases a swift β-ray or electron is liberated. There can be no doubt that these particles are liberated from the nuclei of the radio-active atoms. This is clearly shown by the variation of the atomic numbers of the successive elements in the long series of transformations of uranium and thorium (see Fig. 1) The expulsion of an α-particle lowers the nuclear charge of the atom by two units and its mass by four, while the expulsion of an electron raises it by one. On this simple basis we can at once deduce the atomic number and, consequently, the general chemical properties of the long series of radio-active elements. In this way we can understand at once the appearance in the radio-active series of isotopes, *i.e.* elements of the same nuclear charge but different atomic masses.

The existence of isotopic elements was first brought to light from a study of the radio-active elements. For example, radium-*B*, radium-*D* and the end product, uranium-lead, are isotopes of lead of nuclear charge 82, but of masses 214, 210, and 206 respectively. As regards ordinary chemical and physical properties, they are indistinguishable from one another, differing only in properties that depend on the nucleus, namely, atomic mass and radio-activity. For example radium-*B* and radium-*D* both emit β-rays, but with different velocities, while their average life is widely different. Uranium-lead, on the other hand, is non-radioactive. Many similar examples can be taken from the thorium and actinium series of elements. These illustrations show clearly that elements may have almost identical physical and chemical properties and yet differ markedly in the mass and structure of their nuclei.

From the radio-active evidence it seems clear that the nuclear structure contains both helium nuclei and electrons. In the uranium-radium series of transformations, eight helium nuclei are emitted and six electrons, and it is natural to suppose that the helium nuclei and electrons that are ejected act as units of the nuclear structure. It is clear from these results that the nuclear charge of an element is the excess of the positive charges in the nucleus over the negative. It is a striking fact that no protons (H nuclei) appear to be emitted in any of the radio-active transformations, but only helium nuclei and electrons.

Some very definite and important information on the structure of nuclei has been obtained by Aston in his experiments to show the existence of isotopes in



Uranium-radium series

FIG 1

the ordinary stable elements by the well-known positive-ray method. He found that a number of the elements were simple and contained no isotopes. Examples of such "pure" elements are carbon, nitrogen, oxygen, and fluorine. It is significant that the atomic weights of these elements are nearly whole numbers in terms of O = 16; on the other hand, elements such as neon, chlorine, krypton, and many others consisted of mixtures of two or more isotopes of different atomic masses. Aston found that within the limit of error—about 1 in 1000—the atomic weights of these isotopes were whole numbers on the oxygen scale. This is a very important result, and suggests that the nuclei of elements are built up by the addition of protons, of mass nearly one, in the nuclear combination.

[Experimental evidence was here given of the liberation of protons from the elements boron, nitrogen, fluorine, sodium, aluminium, and phosphorus. See NATURE of May 6, p. 584.]

From the radio-active evidence, we know that the nuclei of heavy atoms are built up, in part at least, of helium nuclei and electrons, while it also seems clear that the proton can be released from the nuclei of certain light atoms. It is, however, very natural to suppose that the helium nucleus which carries two positive charges is a secondary building unit, composed of a close combination of protons and electrons, namely, 4 protons and 2 electrons.

From the point of view of simplicity, such a conception has much in its favour, although it should be mentioned that it seems at the moment impossible to prove its correctness. If, however, we take this structure of the helium nucleus as a working hypothesis, certain very important consequences follow. On the

oxygen scale, the helium atom has a mass very nearly 4·000, while the hydrogen atom has a mass 1·0077. The mass of the helium atom is thus considerably less than that of four free H nuclei. Disregarding the small mass of the electrons, in the formation of 1 gram of helium from hydrogen there would be a loss of mass of 7·7 milligrams.

It is now generally accepted that if the formation of a complex system is accompanied by the radiation of energy E, the reduction of the mass m of the system is given by $E=mc^2$, where c is the velocity of light. This relation between mass and energy follows not only as a direct consequence of the theory of relativity, but can be derived directly from Maxwell's theory, as pointed out by Larmor. On this relation, the energy E liberated in the formation of 1 grm. of helium from hydrogen is equal to $6·9 \times 10^{18}$ ergs or $1·6 \times 10^{11}$ gramme-calories. This is an enormous amount of energy, large compared even with the total energy emitted during the complete disintegration of 1 grm. of radium and its products, namely, about $3·7 \times 10^9$ gramme-calories. It can be calculated that the energy radiated in forming one atom of helium is equivalent to the energy carried by three or four swift α-particles from radium. On this view we can at once understand why it should be impossible to break up the helium nucleus by a collision with an α-particle. In fact, the helium atom should be by far the most stable of all the complex atoms.

It has been pointed out by Perrin and Eddington that in all probability the energy of radiation from our sun and the stars is derived mainly from the enormous emission of energy accompanying the formation of helium from hydrogen. If this be the case, it is easy to show that sufficient energy can be derived from this source for our sun to radiate at its present rate for several thousand million years, whereas the older theories of Kelvin and Helmholtz, in which the heat of the sun is ascribed to the gradual concentration of the material under gravity, make the life of the sun much shorter than modern estimates of the age of the earth and appear to be quite inadequate to provide the requisite energy.

This interesting suggestion of the probable origin of the greater part of the enormous energy radiated by the sun and stars is one of the first-fruits of the investigations on the structure of atoms. It is believed that the formation of helium from hydrogen occurs under certain conditions in the great central furnace of the sun and stars, but there is no evidence, so far, that this combination can be produced under laboratory conditions. It may be that it can be effected only under conditions of very high temperature and enormous intensity of radiation such as occur in the interior of a sun. Even then the process of formation may go on at a very slow rate and for periods measured by millions of years.

Most workers on the problem of atomic constitution take as a working hypothesis that the atoms of matter are purely electrical structures, and that ultimately it is hoped to explain all the properties of atoms as a result of certain combinations of the two fundamental units of positive and negative electricity, the proton and electron. Some of the more successful methods of attack that have been made on this most difficult of problems have been indicated. During recent years, unexpectedly rapid advances have been made in our knowledge, but we have only made a beginning in the attack on a very great and intricate problem.

Great difficulties arise the moment we consider why the nucleus of an atom holds together, and progress seems likely to be slow because it seems clear that the ordinary laws of force between electrified particles break down at such minute distances. There are, however, a number of obvious lines of attack that may yield us very valuable information. In particular, a closer study of the modes of transformation of radio-active bodies, where the process of devolution of elements takes place before our eyes, may be expected to give much important data. During recent years the study of the γ- or very penetrating X-rays from radio-active bodies has progressed very rapidly. The general evidence indicates that the γ-rays, like the α- and β-particle, have their origin in the nucleus. The study of the γ-rays thus gives us information of the frequency of vibration of the electrons which form part of the nuclear structure. In addition, Ellis has shown that it appears probable that the laws of quantum dynamics which govern the motions and vibrations of the outer electrons apply also to the nuclear electrons. If this conclusion can be verified, it offers the hope that we may be able later to form some idea of the detailed structure of nuclei. There are also a number of other lines of evidence that will have to be taken into account in formulating any definite theory of the evolution of the elements; for example, Harkins has pointed out some very interesting relations that appear to exist between the relative abundance of elements in the earth and their atomic number, while the close study of stellar evolution should ultimately throw much light on the general problem.

The Royal Botanic Society's Gardens.

THE gardens of the Royal Botanic Society, Regent's Park, are one of the landmarks of London. They occupy the whole of the Inner Circle of Regent's Park, an area of nearly 20 acres. The accompanying aerophotograph shows very well their main features. The Society was established by Royal Charter in 1839, "for the promotion of botany in all its branches, and its application to medicine, arts, and manufactures, and also for the formation of extensive botanical and ornamental gardens within the immediate vicinity of the metropolis." The first president was the Duke of Richmond, and the first secretary James De Carle Sowerby, a botanist and artist, whose father, James Sowerby, was a well-known botanist in his time. The latter was author of "English Botany," a classic collection of coloured drawings of British plants, and other works. The son, James De Carle Sowerby, inherited his father's tastes as a botanist and artist. He also handed on to *his* son and grandson the office of secretary, the latter resigning shortly before the war.

Their Majesties the King and Queen and Queen Alexandra, and H.R.H. the Prince of Wales are patrons of the society, and the present President is Viscount Lascelles. The grounds of the gardens were originally

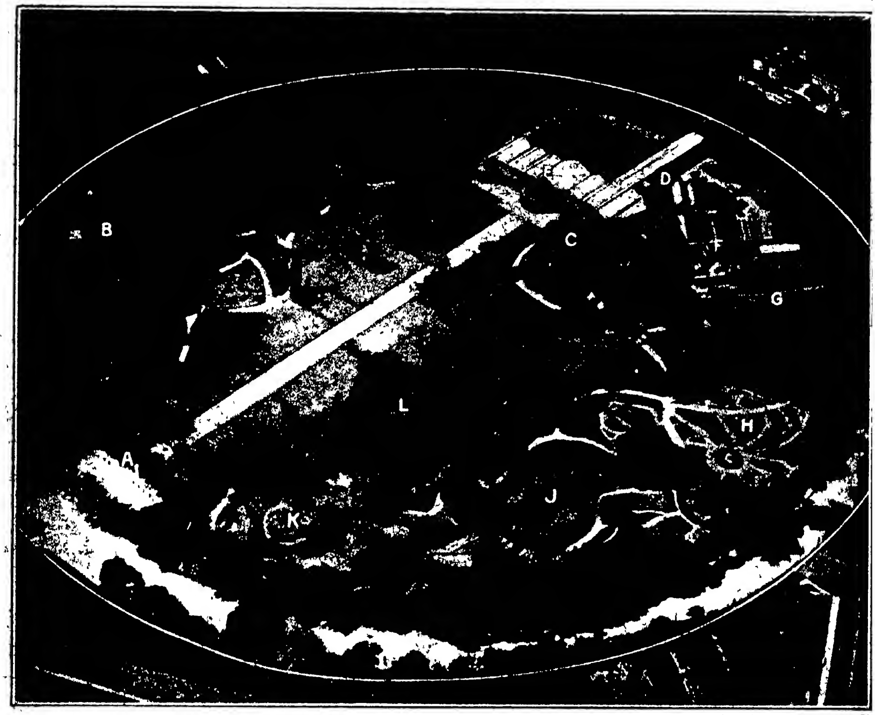
intended as the site for a royal palace, and had been used as a nursery garden. They were cleared and laid out as an example of English landscape gardening, an artificial lake being excavated and a mound formed near the centre of the ground in the process. In 1845 the conservatory was erected. It was the first large iron house built in England, the palm-house at Kew being constructed later. The herbaceous garden, in which the plants were arranged according to the natural orders, was also a novelty in its time. It includes economic and medicinal plants, and has proved very useful to botanical students throughout the history of the gardens. As early as the 'eighties of last century 600-800 students' tickets were issued annually. The gardens have also been and are still an important source of specimens for botanical teaching in London. The kitchen-garden and rock-garden are other features having their special uses.

The greenhouses are now in need of replacement, and that process will begin shortly with the erection of two new and modern houses. The museum contains an important collection of economic products, particularly of tropical plants. The library is chiefly devoted to economic botany, including agricultural and horticultural publications. The Victoria House contains a warm-water tank in which Victoria regia is grown very successfully every year. In the la summer this is one of the sights of the garden In this house are also grown bananas, rice, bambo sugar cane, the sacred lotus, as well as a variety tropical water plants and climbers. Some of the oth houses are devoted to orchids, succulents, ferns, sto plants and bedding plants.

A practical gardening school was established in 189 and has done excellent work. Lady gardening studen were first admitted in 1904, and they have been ver successful. They now number 22, and a new student house was recently built for them. The course i practical gardening extends over three years, an includes practice in all the operations of gardening, a well as a certain number of lectures. Those who hav completed the course have been very successful in th gardening competitions of the Royal Horticultur Society and in obtaining situations.

The gardens are also recognised as a meteorologica station for London. The society possesses a complet set of instruments, and daily observations are mad and published. The records include ground tempera tures and sunlight.

In the years before the war the gardens ceased



[Photo by Central Aerophoto Co.

[illegible] in 1906, a Commission from the University of London considered the possibility of incorporating them into the University and making them the centre of a Botanical Institute, but the scheme was not adopted. Since the war the gardens have taken on a new lease of life. An energetic Superintendent has been appointed, who has already increased considerably the utility and the amenities of the gardens. Ground has been set apart for genetic experiments under the direction of Prof. Ruggles Gates, of King's College, London. Several hard tennis courts have also been built, which are a considerable source of income.

In 1919 a Government Committee was appointed under the chairmanship of Sir David Prain, to consider how the work of the Royal Botanic Society could be made more useful from the scientific and educational point of view. Definite recommendations were made, which it is hoped will be carried into effect as funds become available. The recommendations included (1) the establishment of a School of Economic Botany, where a knowledge of economic and tropical plants and their products could be obtained; (2) an Institute of Research, especially on the living plant and its physiology; (3) a centre for teaching in horticulture; and (4) courses in school gardening for teachers. When these are all carried out they will involve an annual expenditure of about 3000*l.* for salaries and expenses, and an initial outlay of some 5000*l.* for laboratories and equipment. Such an Institute of Economic Botany would be of enormous value to botany in this country, and in particular would contribute much to the economic development of our tropical possessions.

It is highly desirable that the necessary funds for this purpose should be forthcoming in the near future, so that the reconstruction of greenhouses and other buildings, which has become essential, can be carried out in a scheme harmonious with the present arrangements of the gardens. Botany in Great Britain has occupied in some respects a unique position, especially in its many-sidedness and in the closeness of the relations which have usually existed with economic, agricultural, and horticultural interests, and an Institute of Botanical Research of the kind recommended by the Government Committee in 1919 would probably do more than any other measure for the advancement of botanical science throughout the Empire. Any public-spirited citizen who would set the example of subscribing funds for this purpose would earn the gratitude of all those who have at heart the development of botanical science for the welfare of mankind.

Obituary.

S. P. Smith.

THE name of Stephenson Percy Smith, whose death is reported at New Plymouth, New Zealand, is probably more widely known than any other among students of Polynesian ethnology. Mr. Smith was born at Beccles in Suffolk, and arrived with his parents at the infant settlement of New Plymouth on February 7, 1850. In 1855 he entered the Government Survey Department, passing upwards through all grades and becoming Surveyor-General in 1889, a post which he held till his retirement in 1900. Among a number of important and arduous departmental undertakings carried through with conspicuous ability were the survey following the great eruption of Tarawera, and the mapping and charting of the Chatham Islands and the Kermadecs. His ability in affairs was recognised and made use of by the New Zealand Government on several occasions, perhaps most notably when he was dispatched to Niue, where he drew up the constitution under which that island has prospered ever since.

In spite of his varied services to the State, it is in another capacity that he will be best remembered, namely, as the leading authority on Polynesian traditions. A few months before his death a fourth edition appeared of "Hawaiki: The Whence of the Maori," a book which has been more widely read and more often quoted than any other modern work on Polynesia. In its latest form it has been considerably expanded, and it is weightier and more mature, even, than before. He published several other books dealing with the Maori, and a very large number of papers, every one of which is of value.

A service to ethnology almost as important as the publication of his own works was performed by Percy Smith in the capacity of president of the Polynesian Society and editor of its Journal. He was the most prominent of its founders in [illegible], and he presided over it and guided it until his death. Thirty volumes of the Journal have appeared, and the immense industry and the scholarship involved in editing them and in translating numberless papers published in them, would alone constitute a notable life-work. By thus providing a means for the rapid publication of ethnological research in New Zealand and the Pacific he performed a service for anthropology in that part of the globe probably greater than has been rendered by any other worker in the field. He was an honorary member of many scientific societies in different parts of the world, and in New Zealand had been honoured by a Fellowship of the New Zealand Institute, and by the award of the Hector Medal.

No one could meet Percy Smith without recognising the strength and range of his intellect. He rendered ready help alike to great and small. His loss will be felt not only by those who knew him personally and experienced his generous help, but by every student who begins research in the field of which he was the unchallenged master.

H. D. S.

WE notice with regret the announcement of the death, on July 27 last, of Dr. A. J. Harries. Dr. Harries, who was born in 1856 and received his medical education in London and Brussels, was well known for his work on electro-therapeutics and kindred subjects. Among a number of medical works which he published was "A Manual of Electro Therapeutics," issued in 1890; he was also the author of papers on the dangers and uses of electricity, including one contributed to the Leeds meeting of the British Association in 1890, in which it was pointed out that current strength, as well as voltage, is an important factor in estimating the danger to life from accidental contacts with "live" [illegible] structures.

Current Topics and Events.

DR. E. T. WHITTAKER, professor of mathematics in the University of Edinburgh, has been elected a Foreign Member of the Reale Accademia dei Lincei, Rome.

SIR CHARLES PARSONS, inventor of the Parsons steam turbine, Dr J. H. Tudsbery, until recently secretary of the Institution of Civil Engineers, and Mr. C. le Maistre, Secretary of the International Electro-Technical Commission in London, have been elected honorary members of the Royal Dutch Institute of Engineers.

THE D. G. Elliot gold medal of the National Academy of Sciences of the United States of America has been awarded to Dr. O. Abel, professor of palæobiology in the University of Vienna for his work, "Methoden der paläobiologischen Forschung," which forms a part of Abderhalden's "Handbuch der biologischen Arbeitsmethoden."

THE Franklin Gold Medal of the Franklin Institute of Philadelphia was presented on July 26 by Lord Balfour to Sir Joseph J. Thomson, in the presence of a distinguished gathering of men of science from Great Britain, Canada and the United States of America. This medal, which was instituted in 1914 by Samuel Insull, is awarded annually "to those workers in physical science or technology, without regard to country, whose efforts . . . have done most to advance a knowledge of physical science or its applications"

MR. W. H. DINES, Director of the Aerological Observatory of the Meteorological Office at Benson, has retired after many years' service in connexion with the upper air. The *Meteorological Magazine* for July, speaking of his retirement, mentions Mr. Dines as a link with the past. After a training in mechanical engineering, and with a Wrangler's degree at Cambridge, he was specially qualified to undertake the direction and management of an observatory for the upper air. Much of his earlier work was effected with kites. The upper air work is said by Sir Napier Shaw to have been successful beyond hope and expectation, though both were high, and pre-eminence is claimed for the high-water mark of the investigations in this country. Mr. Dines's services to science and the State have been of the highest order and of very special value during the development of aircraft and engines, and the maximum result has been achieved with the minimum of cost. His payment as Director was a small honorarium and out-of-pocket expenses.

A LOAN collection of water-colours of New Zealand, by Mr. C. N. Worsley, is at present being shown in the New Zealand Court of the exhibition galleries of the Imperial Institute. The pictures give an excellent impression of the beauty of the scenery of New Zealand. Among the new collections recently added to the galleries is a representation of the resources of British North Borneo, which includes an exhibit illustrating the important tobacco industry.

THE annual exhibition of the Royal Photographic Society for the present year will be held at 35 Russell Square, W.C.1, from September 18 to October 28, inclusive. The exhibition will comprise the following sections: Pictorial Prints, Pictorial Lantern Slides, Pictorial Colour Transparencies and Prints, Natural History Subjects, Photomicrographs, Radiographs, Astronomical, Aerial, and Spectrum Photographs, Stereoscopic Slides, Scientific Colour Work, and Technical Applications of Photography.

A CONFERENCE of representatives of the various branches of the dairy industry in this country, held on July 28 at the Ministry of Agriculture, under the chairmanship of Sir Francis Floud, was addressed by Prof. H. E. Van Norman, president of the World's Dairy Congress which it is proposed to hold in October 1923 at Philadelphia. At the conclusion of the meeting, the following resolution was passed:—"That this meeting, having heard Professor Van Norman's statement of the objects, etc., of the World's Dairy Congress to be held in the United States of America in October 1923, is of opinion that this country should be adequately represented at the Congress, and it requests the Ministry of Agriculture in conjunction with the Ministry of Health to invite the various Associations and bodies interested in the Milk Industry to nominate representatives to serve on a General Committee to organise the representation of the Industry in England and Wales at the Congress."

MR. NORMAN L. SILVESTER sends us from Pangbourne, Berks, a specimen of Scabious having a remarkable malformation of the head. Presumably a case of forking of the original bud, one "half" has grown to produce a complete head, the other "half" has remained short and produced a few florets only.

MR. K. NORRIS, Purley, writes to record that an albino crested newt (*Molge cristata*) was found in a pond at Sanderstead, Surrey, on Friday, June 30. Instead of the usual form, dark grey or blackish brown, with orange underparts blotched with black, the specimen is creamy white with pink eyes. It is at present exhibited at the naturalist's stores of Mr. G. A. Bentall, 392 Strand, W.C.2.

WE recently mentioned (July 8, p. 54) a communication by Mr. Hazeldene Warren published in the June issue of *Man*, on the subject of the Red Crag Flints of Foxhall. In the July issue of *Man* Mr J. Reid Moir presents a rejoinder to Mr Warren's criticisms. We cannot find space for further reference to the discussion, but think it worth while to direct attention to Mr Moir's reply.

IN an article on radio direction-finding in flying machines in NATURE of July 8, p. 59, it was stated that Mr. Gregory Breit worked out mathematically the nature of the field from the two horizontal coils which are used, but no other names are mentioned. Mr. Breit now writes to point out that the work on

direction-finding was carried out by Messrs. Kolster and Dunmore, and that the use of two horizontal coils as a transmitter was due to Mr. Willoughby. Mr. Breit's own work was confined to the calculation of the radiation from the Willoughby transmitter.

THE Imperial Bureau of Mycology, in addition to its other activities, has recently begun the publication, under the editorship of the director, Dr. E. J. Butler, of the *Review of Applied Mycology*. One of the important functions of the Bureau is the accumulation and distribution of information on all matters connected with the diseases of plants, and the co-ordination of investigations in this particular field of study to enable workers in all parts of the world to keep in touch with recent research. In order that this may be accomplished a complete index of the literature is to be kept, and abstracts of the more important investigations will be published. The review is being issued monthly and several numbers have already appeared. The importance of a periodical of this kind issued by a competent authority is obvious, and if only the abstracting can be maintained at its present high level and the review published punctually, with abstracts well up-to-date, it will be of great service to economic mycologists

MAJOR T. F. CHIPP, Conservator of Forests, Gold Coast, since 1921, and previously assistant director of the Botanic Gardens, Singapore, has been appointed assistant director of the Royal Botanic Gardens, Kew. Major Chipp received part of his early training at Kew and worked as a temporary technical assistant in the Herbarium Later he went as demonstrator in botany at the Birkbeck College, and in 1910 was appointed an assistant Conservator of Forests in West Africa

Our Astronomical Column.

LARGE FIREBALL ON JULY 26 —The Toronto correspondent of the *Times*, in a message dated July 26, reports that a loud explosion shook the ground for 20 miles round Wynward, Saskatchewan, and that a giant meteor was seen to fall into the Big Quill Lake A large fiery ball was observed by many persons in the district to drop from the clear sky, and after it had sunk in the waters of the lake, clouds of steam are said to have risen from the surface

Other reports have come from Vanscoy, south-east of Saskatoon, which is in longitude $107\frac{1}{2}°$ west, and north latitude $52\frac{1}{2}°$. The inhabitants of this neighbourhood heard five or six explosions, and the ground lying between Vanscoy and Pike Lake was severely shaken.

No further details of a definite character have yet been received, and it is difficult from the information at hand to draw safe conclusions other than that a large fireball descended near the places named, and apparently fell to the earth. The date of July 25 or 26 is one when large meteors are usually abundant The principal shower is sometimes directed from near the stars α_1 and α_2 Capricorni The meteors of this shower are often brilliant, and they traverse long paths with slow motion It is quite possible that one of the objects composing this stream may have fallen to the earth, and is identical with the fireball observed

THE SYSTEM OF CASTOR.—This interesting system has been the subject of much research since the earliest known observation of it as a binary by Bradley and Pound in 1719 The determination of the period was nearly hopeless until comparatively recently; until 40 years ago some computers put forward values so large as 1000 years. But with the approach to periastron, which is due in some 30 years, the problem is simplified, and Mr W Rabe, in an exhaustive study of the system in *Astr. Nach*, No. 5164-5, gives the following elements: $a = 6''\cdot06$, $e = 0\cdot5593$, $i = 66°\cdot79$, $\omega = 81°\cdot97$, $\Omega = 32°\cdot55$, T = 1954·73, Period 306·28 years. The probable error of the period is given as 5 years. The orbit coincides practically with the minimum ellipse drawn by Mr Lewis in his Memoir on the Struve double stars. The analysis of the observations by Mr. Rabe supports the suggestion, first vaguely made by Mr. Burnham (Mon. Not. R.A.S., vol. 51), that the fainter star has a fairly close unseen companion, the period being about $8\frac{1}{4}$ years The spectroscopic observations of radial velocity are stated to agree with this hypothesis. The parallax of the system is discussed, and the value $0''\cdot0745$ adopted The combined mass is then 5·74 in terms of the sun, Rabe assigns 3·33 of this to the brighter star, 2·41 to the fainter. If the supposed unseen companion is real then its mass accounts for 0·60 of the 2·41

Both of the visible stars are spectroscopic binaries, and from the velocities measured it had been conjectured that the fainter star was the more massive. This, however, involved the doubtful assumption that the spectroscopic orbits were coplanar with the principal orbit, an assumption rendered improbable by Mr Rabe's discussion As the distant companion C is also a member of the system, there would seem to be at least six components altogether

The proper motion of the centre of gravity could not be given till the mass-ratio was determined. Mr Rabe gives it as $-0^s\cdot0134$ in R A, and $-0''\cdot108$ in Decl Combining this with the radial velocity, and correcting for solar motion, the true velocity is 10·46 km/sec towards R A 305°5, Decl. +42°·5. This agrees with the motion of a group of 22 A-stars of Drift I discussed by Prof Plummer

THE DOMINION ASTROPHYSICAL OBSERVATORY, VICTORIA —Publication No. 26 of vol i. of this observatory contains a list of 88 new spectroscopic binaries discovered there, in addition to the first 100 announced in No 10. The spectrograph is mounted on the 72-inch reflector which is used as a Cassegrain with equivalent focal length 100 feet Analysis of the stars shows that they are distributed through all spectral types, but 90 per cent belong to types B, A and F. Of the B-stars about every second one investigated proved to be binary, suggesting that duplicity may be the normal accompaniment of the attainment of this type, for in some cases the variable velocity would not be detected if its component in the line of sight was small The following star of the pair Σ 1800 (separation $3''\cdot5$) is one of the stars on the list The preceding star has a fixed velocity, while the following one shows in the violet "beautiful sharp double lines with a separation of about 70 km." Another star is Boss 4777, which is the distant companion (46") of β Lyrae.

Research Items.

THE KWAKIUTL INDIANS.—The report of the Peabody Museum of American Archæology and Ethnology, at Harvard University, for 1920–1921, published in 1922, records the results of many expeditions. The one of chief interest to British readers is a visit to the Kwakiutl Indians of British Columbia, made by Dr C. F Newcombe, to look for the few remaining house-posts or other large carvings of those Indians. From Kalukwis village on Tournour Id. he secured two fine house-posts, about sixteen feet high and nearly four feet across Each is carved with figures representing the speaker of the chief and the ancestral grizzly bear who was friendly to the founder of the family, giving him rights to certain dances, and teaching him the use of the appropriate masks These carvings are now on exhibition, and a house group of Kwakiutls has been added to the fourteen previously illustrating the home life of the American Indians. A new Hall of North American Ethnology was opened to the public in September 1920, but it needs more cases before the collections can be finally arranged. With the reduction in the price of plate glass, it is hoped that these cases will soon be added.

THE ETHNOLOGY OF SCANDINAVIA.—Prof. H. F. Osborn contributes to *Natural History* of April last (vol. xxii. No. 2) an article entitled "Our Ancestors arrive in Scandinavia," in which, with good illustrations, he sums up the latest conclusions on its archæology. From the chronological table he argues that "it becomes apparent that what the far-distant north-west was to our American pioneers, what Ultima Thule was to ancient historic times, such was Scandinavia to the people of the Mediterranean borders. In the course of thousands of years implements, symbols, and inventions—useful, religious, or artistic—slowly found their way westward and northward, from Eastern Asia to Sweden, a distance which, thanks to the telephone, is to-day spanned in a few seconds. For example, copper is said to have been used at Anau, Turkestan, about 4000 B C, and first appears in Sweden 1500 years later—namely, 2500 B.C. The Age of Bronze, which was in full sway in Egypt and Chaldea by 3000 B C, makes its first appearance in Sweden eight hundred years later. Thus within a period of eight thousand years our ancestors arrived in Scandinavia and passed through a long hunting stage of evolution with only flint implements; through all the Neolithic phases; through a superb development both of the art of flint and of bronze; into the culminating period of the Age of Iron."

THE FORGING OF FINGER-PRINTS.—It is disconcerting to learn from an article by Mr. J C Goodwin in the third number of the new publication, *Dactylography*, that the practice of forging finger-prints is increasing and will soon become a problem for New Scotland Yard. The criminal must first obtain specimens of the prints of the dupe on whom he intends that suspicion should fall This he does by arranging that the dupe leaves his prints on a glass, or on a polished piece of furniture, after which the prints are photographed. One method of forging involves the use of a rubber stamp, where a facsimile of the original is reproduced on the rubber by means of transfer paper, and the surrounding rubber deftly pared away with a sharp knife. The second method is to take a negative cast of the finger to be forged by pressing it into a mould of soft wax, plaster of Paris, clay, or even bread. A third process involves photographing a photograph of the prints to be forged on a reversed plate, which is clamped to a duplicate plate made of gelatine mixed with bichromate of potassium. The two are exposed to the light, with the photographic negative nearer to the light, and the sensitised surface touching the gelatine.

FOSSIL FISH FROM SOUTHERN ITALY.—Prof. Geremia D'Erasmo describes and figures in the Rendiconto dell' Accademia delle Scienze, Napoli (Ser. III., vol. xxviii.), some fossil fish from southern Italy. They comprise an almost complete Picnodont (*Cœlodus costati*, Heckel) from the cenomanian beds of Alessano, province of Lecce, where examples of this group are scarce; a Leptolepis from the cretaceous of Roccadevandro, province of Caserta; as well as a Seriola, a Thynnus, two species of Clupea, and a Pelamys from the pleistocene strata of Taranto.

REDESCRIPTION OF AN EOCENE LIZARD.—Discovered and described fifty years ago, the remains of *Saniwa ensidens*, Leidy, from the Bridger deposits (Eocene) of Wyoming, have only recently been properly developed from the matrix. The unusual perfectness of the skeletal remains thus revealed have justified their redescription by Mr. C. W. Gilmore (Proc. U.S. Nat Mus, vol lx.) The fossil proves to be a true member of the family Varanidæ, which therefore contains the genus Varanus, largely made up of living species of lizards, and the genus Saniwa, which now includes six or more extinct species, since Marsh's Thinosaurus is considered by the author as congeneric with Saniwa

OWL FROM THE EOCENE OF WYOMING.—A fragment of a humerus and two vertebræ from the Bridger deposits of Wyoming were referred in 1873 by Dr. J. Leidy to a lizard which he named *Saniwa major.* The humerus is now shown by Mr. A. Wetmore (Proc. Acad. Nat Sci, Philadelphia, vol lxxiii) to be avian and to represent an owl of the family Bubonidæ, similar in size to *Pulsatrix perspicillata*, Latham. It does not resemble closely any existing genus of modern North American owls, but in a way combines characters pertaining to several The author assigns it tentatively to Shufeldt's genus Minerva under the new trivial name of *M. saurodosis*, but admits that that genus, founded on a claw at first referred to Aquila, although from the same formation and district, may yet prove to be an incorrect receptacle for the new species.

SYSTEMATIC BOTANY.—The forty-seven articles of the latest volume of the Kew Bulletin (Bulletin of Miscellaneous Information, Royal Botanic Gardens, Kew, 1921; 10s net) are an index of the activities of the Royal Gardens They are mainly of systematic interest, including revisions of genera, descriptions of novelties, and notes on plants of botanical or economical importance. A point of general interest which emerges is the indication of the great amount of work which remains to be done before we can have an accurate knowledge of the constituents of the floras of the different parts of the world. The revision of the Stipa grasses of Australia (by Miss D. K. Hughes) indicates 40 distinct forms in place of the 15 hitherto recognised; it also bears out the common experience, that variation in anatomical structure of the leaf-blade of grasses does not run parallel with the characters of leaf and flower from which we infer their relationships. The incomplete state of our knowledge of the Central American forest flora is well illustrated by a revision of the genus Belotia, and of the family Tiliaceæ, in which T. A. Sprague distinguishes eleven species, an increase of six on the number hitherto recognised.

A difficulty which the economic botanist frequently meets is illustrated by an inquiry (by S. T. Dunn) into the cause of the variability in the yield of camphor from the Camphor tree (*Cinnamomum Camphora*). Some trees are found to be worthless, the oil yielding no solid camphor on distillation. Careful examination discloses no perceptible botanical difference between good and worthless trees, but there may be peculiarities which affect only the chemical products of the tree. Such physiological varieties are known in rubber and timber trees Investigation indicates that climatic conditions, the age of the leaves when cut for distillation, and the general health of the tree have an important bearing on the yield.

BRITISH AND IRISH PAGURIDEA —The Paguridea (including hermit crabs and the stone crab) which have been found on the coasts of Ireland had been studied by Mr C. M. Selbie, of the National Museum, Dublin, who died at the Somme in July 1916. The account now published (Fisheries, Ireland, Sci. Invest. 1921, I) has been completed from Mr. Selbie's rough drafts by Dr S W Kemp. The material reported upon, nearly all obtained by the Irish Fishery Cruiser, contains eleven species, one of which—*Nematopagurus longicornis*—has not hitherto been known from British waters. To complete the list of British and Irish representations of this tribe there are to be added an Irish species of Eupagurus recorded in 1866, and two species—one Diogenes and one Anapagurus—known from the shores of Great Britain but not yet discovered in Irish waters—a total of fourteen species The majority of the species inhabit water that is shallow or of moderate depth, but one—*Parapagurus pilosimanus*—is a true deep-water species and occurs at depths ranging from 250 to 2260 fathoms Three of the fourteen species extend north of the Arctic Circle and eight are found in the Mediterranean There are keys to the families, genera, and species, and a systematic account is given of each species with notes on its distribution.

THE SEMI-DIESEL ENGINE.—Owing to the high price of fuel in France at the present time the Mechanical Arts Committee of the Société d'Encouragement pour l'Industrie nationale has thought it desirable to publish an account of the present position of the semi-Diesel engine, and in consequence the May issue of the Bulletin of the Society contains an article of nearly 100 pages on the subject from the pen of M A. Schubert It goes into the theory of the engine, the reasons which have led to its development, the forms which it at present takes in France and in other countries, and the oils which can be used in it. Under the last head the author deals especially with the vegetable oils which are produced in great quantities in the French colonies in Africa and in Asia It concludes with a short account of the tests of such engines carried out recently by the Society in conjunction with the Automobile Club of France and the marine and agricultural authorities. From the results we gather that several engines of horse-powers from $2\frac{1}{2}$ to 50 show a consumption of oil of the order of 320 grams per h p. hour, while one of 20 to 30 h p consumes 247 grams only. M. Schubert's article, while intended primarily for French engineers, will be found of great value by the engineers of this country.

UNDERGROUND WORKROOMS —In the Annual Report of the Chief Inspector of Factories for 1921 special reference is made to conditions in underground workrooms. Of the 300 rooms inspected during the inquiry a number were expressly designed for use as workrooms and the conditions were satisfactory. But others were never intended for use in this way, and the structural conditions render it impossible to secure good lighting, ventilation and sanitary conditions. Of the rooms visited about 61 per cent. were provided with means for flushing the rooms with air, in 20 per cent. the through ventilation was only partial, and in 19 per cent. it appeared that there was practically no through ventilation. It was considered that the state of the air was fresh or satisfactory in 68 per cent of the rooms, while in 24 per cent it appeared to be close or stale, and in 8 per cent. stagnant In approximately 78 per cent. of the rooms the natural light was deemed insufficient to light the whole of the room, but, fortunately, in most cases the artificial lighting was considered satisfactory in intensity although glare due to imperfectly screened lamps appears to be common. There is no doubt that access of light through windows is often neglected; in some cases broken windows are obscured by sacking, cardboard, etc Daylight is undoubtedly superior to all but the very best artificial lighting, and the effect of a mixture of daylight and artificial light is rarely satisfactory. Every effort should therefore be made to secure the maximum admission of natural light in underground buildings Another drawback to the use of basements as workrooms is the tendency for dust to enter from the pavement outside. Mention is made of a case where a trough fitted under a grid ventilator at pavement level was found to be filled by about a quart of black dust. Muslin or gauze is sometimes fitted over ventilator-entries to prevent dust entering, but the pores of the material are liable to become choked and it requires frequent washing

A CHEMICAL SPECTROMETER —A spectrometer of entirely novel design has recently been produced by Messrs Adam Hilger, Ltd., of 75a Camden Road, N.W.1. By the application of an autocollimating telescope the designer has been enabled to dispense with the collimator tube of the ordinary spectrometer. The arrangement of the components is shown in the sectional drawing, Fig 1 The eye-piece E of the telescope contains, on the left, the slit and small autocollimating prism for introducing the light which, after passing through the object glass O, proceeds to the 30° prism P, is reflected from the silvered back surface and re-traces its path through the object glass to the eye-piece where the spectrum is viewed. The prism is rotated by means of a micrometer screw which is attached to a drum D giving readings direct in wave-lengths. The design of the instrument renders it extremely compact In size and external appearance it is similar to a microscope and occupies about the same amount of table space It has the additional advantage of ease in setting up, convenience in manipulation and low cost, compared with a spectrometer of the ordinary type having a similar degree of accuracy. Such an instrument should tend to encourage the more general use of spectroscopic measurements in chemical laboratories.

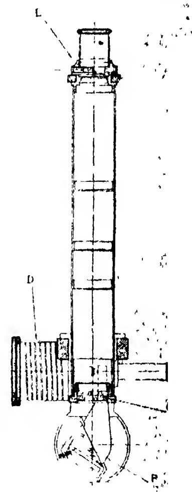

FIG 1

The Norman Lockyer Observatory.

UNVEILING OF A PORTRAIT MEDALLION OF THE FOUNDER.

ON Saturday, July 22, a portrait medallion of Sir Norman Lockyer was unveiled by the Astronomer Royal, Sir Frank Dyson, at the Norman Lockyer Observatory, Salcombe Hill, Sidmouth, in the presence of a large and distinguished company. The medallion, which had been executed by Sir Hamo Thornycroft, R.A., was erected in honour of the late Sir Norman Lockyer by his relatives and friends, and was presented by them to the Corporation of the Observatory. (A reproduction of the medallion, with the accompanying inscription, is illustrated in Fig. 1.) The guests were received on behalf of the Observatory Corporation by Sir Richard Gregory (chairman of the council), Mr. Robert Mond (chairman of the Corporation), and by Lady Lockyer. Much interest was taken by the guests in the exhibits arranged in connexion with the work of the observatory, the McClean and Kensington telescopes and other instruments.

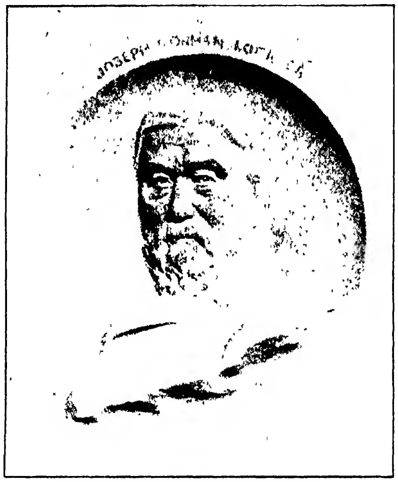

FIG. 1.—Portrait Medallion of Sir Norman Lockyer.

17TH MAY, 1836 – 16TH AUGUST, 1920
TO THE ENDURING MEMORY OF THE GENIUS AND CONSTRUCTIVE IMAGINATION OF
SIR NORMAN LOCKYER, K.C.B., F.R.S.,
CORRESPONDANT DE L'INSTITUT DE FRANCE,
HON. LL.D., GLASGOW, ABERDEEN AND EDINBURGH, HON. SC.D., CAMBRIDGE AND SHEFFIELD,
HON. D.SC., OXFORD

FOUNDER AND DIRECTOR OF THE SOLAR PHYSICS OBSERVATORY, SOUTH KENSINGTON, 1885-1913, AND OF THIS OBSERVATORY, 1913-1920
FOUNDER AND EDITOR OF "NATURE," 1869-1919
PIONEER IN THE INVESTIGATION AND INTERPRETATION OF THE CHEMISTRY OF THE SUN AND STARS AND IN THE SCIENCE OF ASTRONOMICAL PHYSICS
DISCOVERER OF HELIUM IN THE SUN AND ORIGINATOR OF THE THEORY THAT HELIUM AND HYDROGEN ARE THE ULTIMATE PRODUCTS OF THE DISSOCIATION OF MOLECULES AND ATOMS
FOUNDER OF THE SYSTEM OF STELLAR CLASSIFICATION BASED UPON ASCENDING AND DESCENDING TEMPERATURES IN ORDERLY CELESTIAL EVOLUTION
REVEALER OF THE ASTRONOMICAL SIGNIFICANCE OF STONEHENGE AND OTHER ANCIENT MONUMENTS
FOUNDER OF THE BRITISH SCIENCE GUILD FOR THE PROMOTION AND APPLICATION OF SCIENTIFIC METHOD TO PUBLIC AFFAIRS

THIS PORTRAIT WAS ERECTED BY RELATIVES AND FRIENDS

In opening the proceedings Sir Richard Gregory remarked that they had assembled to take part in a ceremony of high significance both to the county of Devon and to British science. On the summit of Salcombe Hill, with its clear and wide horizon, they had united to dedicate with affection and esteem a memorial to the great astronomer, Sir Norman Lockyer, who had planted the observatory there. The event was one in which they might all be proud to participate, whether as Sir Norman's personal friends, as admirers of his life and influence, or as scientific students familiar with the remarkable advances of astronomical physics originated by him or inspired by his genius. His discoveries were inscribed upon the tablets of the stars, and in this temple of the skies they now met to manifest in reverence the honour in which they held him.

Lt.-Col. F. K. McClean said that he regarded it as a great honour to present, on behalf of relatives and friends, the medallion, so faithfully executed by Sir Hamo Thornycroft, to the observatory. It was his good fortune to have been associated with Sir Norman in the foundation of the observatory in 1912. Through the energy and enthusiasm of Sir Norman the observatory has proved a successful enterprise, and commencing as a private institution it has become a Corporation and is the first of its kind in this country. American observatories are more useful now, but the Norman Lockyer Observatory, though at present a baby, will grow and develop, and what its future may be can be seen by looking at the Mount Wilson, Yerkes, and Lick Observatories. So long as the observatory lasts, the name which it has the honour to bear will be the watchword of advance.

THE ASTRONOMER ROYAL'S TRIBUTE.

Sir Frank Dyson, in unveiling the memorial, said:

This portrait medallion is a pious tribute of relatives and friends to the memory of a man of genius. It recalls to our minds the features of a man we have known and honoured, and preserves his likeness for future generations. The name of Sir Norman Lockyer will always be associated with the application of the spectroscope to the study of the sun and stars. In this beautiful medallion Sir Hamo Thornycroft has given a true and striking portrait of a very earnest worker and great pioneer.

Like David Gill, another astronomer whom most of us know, Lockyer began as an amateur with

a telescope in his garden and devoted his spare time to astronomy. The two men were alike in their energy and intense enthusiasm. One sees on nearly every page of his book on "Solar Physics," published in 1893, the delight which Sir Norman took in his work. He makes one feel that the years following Kirchhoff's explanation of the dark lines in the solar spectrum were glorious times for astronomers, who suddenly found a way to explore the chemical and physical constitution of the heavenly bodies. One could scarcely say that each day brought a new victory, but new victories and new problems followed one another very rapidly.

When Sir Norman Lockyer commenced his work in 1866, current views on the constitution of the sun were very different from those we now hold. Although Herschel's idea of the cool dark interior had been given up, some traces of its influence still remained. Faye conceived of the interior of the sun as a nebulous gas of feeble radiating power at a temperature of dissociation, the photosphere, on the other hand, being of a high radiating power and at a temperature sufficiently low to permit of chemical action In the sunspot we see the interior nebulous mass. Balfour Stewart and De la Rue were opposed to this view and explained a sunspot as due to an inrush of matter from the sun's atmosphere into the photosphere. With a small direct-vision spectroscope on a 6½-inch equatorial, Sir Norman Lockyer examined the spectrum of a sunspot and compared it with that of the surrounding photosphere He found no bright lines, but the same absorption lines as in the solar spectrum, and so far as he could judge with his small dispersion rather broadened. This supported Balfour Stewart rather than Faye. In a paper communicated to the Royal Society he laid stress on the importance of *detailed* spectroscopic study of the sun's surface He also puts the question, "May not the spectroscope afford us evidence of the existence of the 'red flames' which total eclipses have revealed in the sun's atmosphere; although they escape all other methods of observation at other times?"

With the aid of funds from the Government Grant Committee he proceeded to construct a solar spectroscope of sufficient dispersion, and on October 20, 1868, wrote to the Royal Society: "After a number of failures which made the attempt seem hopeless I have this morning perfectly succeeded in obtaining and observing part of the spectrum of a solar prominence. As a result I have established the existence of three bright lines in the following positions:

I. Absolutely coincident with C.
II Nearly coincident with F
III Near D

The third line is more refrangible than the more refrangible of the two darkest lines by eight or nine degrees of Kirchhoff's scale"

A similar communication was made to the French Academy of Sciences, and in addition, the form of the prominence was roughly drawn. The letter to the French Academy was followed by a communication received the same day from M Janssen reporting the success of an expedition to observe a total solar eclipse During the eclipse the idea had occurred to him of how the red flames could be made visible without an eclipse, and he carried it out on the following day. In this dramatic manner the observations of prominences was started, and their gaseous nature proved. The French Government struck a special medal in memory of the discovery and in honour of the discoverers.

Observation of prominences was after this success carried on with renewed vigour. By the simple device of widening the slit the forms of the prominences were seen in C or F light. A further important discovery was made almost at once. Sir Norman Lockyer found that bright C and F lines were visible all round the sun. In this way was discovered the existence of a continuous envelope round the sun of fairly uniform height except where it was heaped with prominences. This envelope was named the chromosphere and it was estimated to be about 5000 miles thick.

The behaviour of the F line, which is described as sometimes exceedingly brilliant and widening out so as to present a bulbous appearance above the chromosphere, and the existence of the line near D with no corresponding Fraunhofer line, suggested work in the laboratory. This was undertaken in conjunction with Edward Frankland These investigations showed that the yellow D_3 line could not be obtained in the spectrum of hydrogen, however the conditions were varied It was attributed by them to a new element, a light gas, as yet undiscovered on the earth, and the name helium was given to the element producing the line. As is well known, the D_3 line and allied lines were found to have great importance in stellar spectra, and in 1895 was found by Ramsay in a gas from the mineral cleveite. The subsequent history of helium and the prominent part it has played in physical science makes its initial discovery by Lockyer in the sun, twenty-six years before it was found on the earth, a most interesting episode in the history of science

These laboratory experiments of Lockyer's and Frankland's are of great importance Sir Norman had a strong conviction, at this early date, that research should be carried on concurrently in the observatory and the laboratory The spectra found in the observatory were to be interpreted by experiments on the differences produced by temperature, pressure, and varied methods of electric excitation. In this way spectroscopy would lead to knowledge not merely of the chemistry, but of the physical conditions of the heavenly bodies. One immediate conclusion was that the continuous spectrum did not necessitate a solid or liquid photosphere but could arise from a gaseous body. Further, that the absorption indicated by the Fraunhofer lines may take place in the photosphere itself, or very near it, and not in an extensive outer absorbing atmosphere. How fruitful this method of research became in his hands and those of his pupils we all know

At South Kensington his work was to a large extent a natural development and exposition of the views he had previously formed. The idea of the dissociation of elements at increasing temperature led to a very extensive comparison of the arc spectra of metals with those obtained in the higher temperature or more intense electric conditions of the spark. In 1881 he found that the iron lines 4924·1 and 5018·6 were greatly enhanced in brightness when one changed from the arc to the spark spectrum The lines of iron, titanium, manganese, chromium, and many other metals were exhaustively investigated at South Kensington. The names of Proto-Iron, Proto-Titanium, etc., were given the metals when in condition to give these enhanced lines. We know now more definitely that what was described as dissociation is loss of an electron, and that when this occurs the enhanced lines appear.

It is scarcely possible to exaggerate the important results which have accrued from the study of enhanced lines. They have contributed greatly to the interpretation of solar and stellar spectra, and have assisted in the sorting out of lines of different elements into series.

In the course of his life Sir Norman Lockyer made observations of no less than eight total eclipses of the sun. His use of a spectroscope without slit led to a

continuous increase of our knowledge of the spectrum of the chromosphere and corona. It has always seemed to me that the most successful of all eclipse expeditions was the one which he led in 1898 and in which he had Prof. Fowler and Dr. Lockyer among his assistants. The differences between the chromospheric and Fraunhofer Spectrum were clearly shown as regards the hydrogen and helium lines and the numerous enhanced lines of many metals. In addition the wave length of the principal corona line was determined and some hypotheses as to its origin disposed of finally.

In 1887 Sir Norman Lockyer put forward a scheme of stellar classification in which the stars were arranged according to an ascending and descending scale of temperature He presented his views in a connected form in his book on "The Meteoritic Hypothesis," published in 1890 In 1902 he published "A Catalogue of 470 Stars classified according to their Chemistry," from material accumulated at South Kensington with an objective prism and studied in the light of laboratory researches. For a long time he stood alone. If we refer to the book of such a learned and judicious astronomer as Newcomb, we find in 1901 ("The Stars," pp. 220-225) that he takes a linear order of development of the stars from the blue to the red, with the sun at about the maximum temperature in the series. Sir Norman could not get over the difficulty that a great orb like Betelgeuse or Antares must be in a widely different condition from a small star like Gr. 24 or Kruger 60 With great freshness of mind and boldness of onlook he framed the meteoritic hypothesis. A comet served as his model for the nebulous beginning of a star With gradual contraction temperature increased in accordance with Lane's Law till the B stage was reached, after which cooling began, so that in the course of its history a star went twice through the yellow and red stages

Twenty years later Prof. H N. Russell, bringing together facts and arguments from many sides, has confirmed Sir Norman's main idea. He has shown that stellar evolution proceeds in the line of increasing density, and that stars of the same temperature may be divided into giants and dwarfs in Prof. Hertzsprung's phrase—in the giants the temperature is increasing and in the dwarfs decreasing

Sir Norman did not succeed in finding the spectroscopic criteria for giving the sizes of stars These were found later by Adams and Kohlschulter at Mount Wilson It is very pleasant to be able to direct attention to the success attending work in this direction now carried on at the Norman Lockyer Observatory.

I cannot conclude without expressing in one sentence the deep obligations which all men of science owe to Sir Norman Lockyer for founding NATURE. One cannot speak too highly of the usefulness of this journal or of the pleasure one takes in reading it each week. Its long continuance is a testimony to the wisdom and foresight of its founder.

The few remarks I have made have dealt very briefly with the main lines of Sir Norman Lockyer's contributions to astronomy—The constitution of the sun—the variety and relationship of terrestrial spectra—stellar evolution. To each of these questions he brought a very fresh mind, and attacked them with courage and imagination. He was a great pioneer of solar and stellar physics. This portrait medallion with its inscription commemorates him in the most suitable place in the observatory which he founded, and which is faithfully carrying on the search prosecuted by him so diligently and successfully into the nature of sun and stars.

CONSTITUTION AND WORK OF THE OBSERVATORY

Sir Richard Gregory, in expressing the grateful thanks of the Corporation to the subscribers for their most acceptable gift, said:

As one who had the privilege of being associated with Sir Norman in different capacities for nearly thirty years, as research student, assistant editor of NATURE, and in connexion with the great national organisation—the British Science Guild—created by him in 1905, perhaps I may be permitted to add my tribute to what the Astronomer Royal has said, and to state briefly what this observatory stands for and what we hope it will be in the near future Sir Norman Lockyer was seventy-six years of age when he started to establish the observatory in 1912, and this in itself is sufficient to show his unbounded zeal and energy An appeal for funds was made, and some generous supporters came forward, but the means for providing the necessary buildings and equipment, the site itself, and sums for maintenance for several years, were supplied mainly by Sir Norman and Lady Lockyer and Lt-Col Frank McClean. The observatory was incorporated in 1916, and its constitution is entirely democratic. Each member of the corporation, whatsoever his contribution, has a single vote, and membership is open to any one approved by the council.

The corporation is unique in its purpose and its constitution. It exists solely to maintain and develop this observatory, not for financial profit but for the gain of knowledge of the heavens Its foreign members include some of the leading astronomers of the world, and a Research Committee, consisting of Sir Frank Dyson (Astronomer Royal), Prof Eddington (Cambridge University), Prof Fowler (Imperial College, South Kensington), and Prof. Turner (Oxford University), advises upon work which may be usefully undertaken. The management and control of the observatory are vested in the council, which is elected by the members.

In these days it may be difficult for some people to realise that a corporation can be formed in which all the services of the council and advisory committees are performed voluntarily, yet such is the case with this observatory corporation. Were it not, indeed, for gifts by members of the corporation, among them the Maharaj Rana of Jhalawar, Mr. Robert Mond, Miss Leigh Browne, Capt W. N McClean, and others, as well as for work willingly and freely undertaken, the observatory could not exist In order to provide, however, for the salaries of the staff and general maintenance of the observatory, even on the present basis, it will be necessary to raise the sum of, at least, fifteen thousand pounds, as the funds hitherto subscribed provide less than one-half the annual income required to meet expenses. We are fortunate in having as director of the observatory Major Lockyer, and it is really wonderful what he manages to accomplish with his assistant, Mr D. L Edwards. There is no observatory in the kingdom where more photographs are being taken of the spectra of the stars, from which we learn something of celestial chemistry and are able to classify them from their beginnings as vast attenuated masses up to fervid suns which afterwards cool and condense to the dull redness and darkness of decaying worlds. A generation ago, celestial evolution was believed to proceed entirely on a down grade of temperature from the condition of incandescent gas in a nebula, but Sir Norman Lockyer showed that there is an ascent as well as a descent in stellar temperature, and this key to the classification of the stars is now generally accepted by astronomers.

The large number of photographs of stellar spectra accumulated by Sir Norman Lockyer, and largely

taken at this observatory under his direction and that of his son, are now being used to determine the distances of stars by a method due to Prof. W. S. Adams, one of the foreign members of the observatory. The measurements are being made by Mr. D. L. Edwards and Mr. W. B. Rimmer. The Department of Scientific and Industrial Research has made a grant to the latter for the purpose of carrying out a portion of this research while attached to the observatory. The equipment and opportunities here for both education and research in the physics and chemistry of celestial bodies are as full and free as could be desired by the most progressive student or investigator. The endowment of two or three research scholarships tenable at this observatory would be the best service that could be rendered to astronomy, and would certainly result in notable increase of our knowledge of the heavens.

It is remarkable that in the United States funds are provided for observatories and astronomical work, by both university institutions and private benefactions, on a scale far beyond anything available in this country. We once led in astronomy, but America now surpasses us both as regards great observatories and remarkable achievements. Whatever funds are required for buildings, equipment, and workers are readily forthcoming, whereas here benefactions for astronomical work are extremely rare. The Mount Wilson Observatory, where the best astronomical work in the world is now being carried on under the direction of Dr G. E. Hale, one of our foreign members, cost more than a quarter of a million pounds, and has an annual income exceeding 40,000*l*. It possesses a 100-inch telescope, upon which more than 100,000*l*. has been expended, and it was in connexion with this instrument that nearly two years ago the remarkable achievement was accomplished of measuring the diameters of certain stars, among them the star Antares, which proves to have a diameter of 400 million miles. The Yerkes Observatory, Lick Observatory, Harvard College Observatory, and Lowell Observatory are other examples of great astronomical institutions in the United States which we both admire and envy. The difficulty there is not to obtain funds for astronomical work, but men who will devote their lives to it: here we have plenty of men eager to take up astronomical research but no means to provide them with the necessary instruments and modest salaries to maintain them.

The Norman Lockyer Observatory is the only institution of its kind in this country, and it owes its existence to the generosity of a few people who believe that to place here a temple devoted to the increase of knowledge of the heavens is to provide a mansion in the skies. The county, the nation, and the whole world of science, owe a deep debt of gratitude to the founder and to his supporters, for this fine building reaching out high unto the stars to question them and understand the messages they send us in their beams. For the means to continue and extend the work so nobly instituted and profitably begun, we appeal to all who are interested in the pursuit of knowledge for its own sake or because of its uplifting influence upon the spirit of man. In faith and hope we ask that this memorable occasion shall mark the beginning of a new and enlarged stage in the history of this observatory, and that the future will see upon this site a centre of modern astronomical research which will maintain the prestige of British science throughout the world and be a worthy memorial to the renowned astronomer who built here this tower from which the heavens can be scanned for intellectual expansion and the enlightenment which the spirit of man is ever seeking as to his destiny.

Col. J. E. H. Balfour, High Sheriff and Lord of the Manor of Sidmouth, expressed on behalf of the county appreciation of Sir Norman's association with Devon and the neighbourhood of Sidmouth. While Sidmouth was famed for its natural advantages of climate and scenery, it was little thought that these advantages would be turned to such wonderful and useful purposes. He was glad to know that the confidence felt in the suitability of the site for the observatory had been amply justified, and he deemed it an honour to Sidmouth to possess such an observatory. He expressed the wish that the observatory would have a great future in the advancement of science and knowledge that it deserved.

The Rev. J. S. Cornish recalled that in his memory the grounds of the observatory were formerly one of the wildest and least useful parts of Salcombe Regis. He little thought it possible that from such an expanse of waste would arise an institution that had already become known throughout the scientific world. He referred to the stone of the old sun-worshippers which still stands near the observatory land where now the modern astronomer reads the truth of the stars with his magnificent telescopes. He hoped that the observatory would become increasingly famous throughout the world, as was the heart's desire of its founder, Sir Norman Lockyer.

Lady Lockyer heartily thanked those who had assembled that day for the unveiling ceremony. Sir Norman looked forward to the observatory being a place where research students could carry out investigations in any branch of spectroscopic research. The provision of a library was essential to house the large collection of books. This would cost about 2000*l*. and they had not that amount of money to spend on it. She hoped a much greater interest would be taken in the work of the observatory, and that the expansion of its activities would not suffer from lack of support. Lady Lockyer expressed the gratitude of Sir Norman's family that his portrait was erected in the observatory which he founded and directed, and which now, by the wish of all the members, bears his name.

Pioneer Work in Submarine Cable Telegraphy.

THE jubilee celebrations of the Eastern Associated Telegraph Companies are so nearly contemporaneous as to seem to be almost part of the commemoration of the foundation of the Institution of Electrical Engineers, which antedated that of the Company by only a few months. These celebrations carry with them a warning not to lose our sense of historic proportion: they remind us that before a Society of Telegraph Engineers could be established, telegraph engineering had already been well founded, and that the great submarine cable company which now for fifty years has served the Empire and the whole world with such conspicuous ability and commercial success could scarcely have been the concept of the earlier pioneer days. Only when the art of submarine telegraphy had been amply assured of success could so great a commercial undertaking as that which the Eastern Telegraph Company is now celebrating be initiated.

The following notes on the pioneer work of the cable engineers and others have been drawn freely from the discourse which Sir Charles Bright delivered at the Electrical Engineers' commemoration.

Perhaps it is a little far-fetched to treat quite

seriously the earliest suggestion that electric signals might be sent under the sea. Yet it is worth while to note that so early as 1811 an effort was made to discover a suitable insulating covering for a submarine wire and that the material used was india-rubber. The decisive factor whereby submarine telegraphy became a practical proposition was, however, contributed by Dr Werner Siemens in 1847 when he laid a telegraph cable in Berlin with wires insulated by gutta-percha. Faraday, as Sir Charles Bright reminds us, was also at the same time directing attention to the insulating properties of this new material. Gutta-percha has never from that day to this had a serious rival for insulation of deep-sea cables.

Not that the pioneers had waited for it! Previously, in June 1845, the brothers Brett, although only small shopkeepers, in the true spirit of the old merchant venturers applied for government sanction to the provision of telegraphic communication between England and France. When the concession came in 1849, gutta-percha had come into its own and most of the cable laid was of copper wire with a half-inch coating of gutta-percha The need for a special "shore-end" was recognised even then, but it is puzzling to know why a different insulation should have been adopted Yet we read that "the shore-ends for about 2 miles from each terminus consisted of a No 16 BWG. conductor covered with cotton soaked in indiarubber solution, the whole being encased in a very thick lead tube" It is scarcely surprising that it failed, but not before, by transmission of a few signals, it had demonstrated the practicability of ocean telegraphy A "mad freak," a "gigantic swindle," but, like many another failure, a signpost to success. The next year a new concession was secured and the Submarine Telegraph Company was formed, but it was only floated on the capital of a railway engineer (Thomas R. Crampton) and his friends. The resulting cable, not completed until the end of 1851, marked another development of the engineer's art in cable-making. Kuper, a colliery engineer, suggested sheathing the insulated wire with iron wires like a colliery pit rope, and so was reached the essential, and till now the final, form of the successful and trustworthy submarine cable.

Perhaps one day some one will write a work on "Government *versus* Enterprise" in the hope that responsible public servants may be taught by their predecessors' failures In 1850 the Bretts again found that, "although sensible of their perseverance in bringing the submarine telegraph about," the Government could do nothing to help, and so—"landing rights" not having yet been invented—the Bretts proceeded on their own responsibility to span the Irish Channel. Ultimately success was achieved in 1853, with Charles Tilston Bright (aged 21) in command as engineer to the Magnetic Telegraph Company.

These efforts, however, although they had demonstrated the practicability of submarine telegraphy, had not finished the work of the pioneer—the great unfathomed depths of ocean had yet to be spanned. To put a cable miles deep on the bed of the Atlantic would be impossible, it was said, even if signals could be passed through the enormous length of 2000 miles. Of course pioneers are never very anxious to do anything but the impossible; so J W. Brett, Cyrus Field (a wealthy American business man who incidentally had discovered, or perhaps invented, "landing rights" for Newfoundland) and Charles Bright (as engineer) projected and with other venturers formed the Atlantic Telegraph Company and secured the required capital in a few days. This was of course only the beginning of the pioneer engineers' work. The British and the United States Governments encouraged and helped the scheme with men-of-war, and at last on August 5, 1858, the shore-end having been duly landed at Newfoundland, the telegraph had bridged the ocean, and the *Times* could say "since the discovery of Columbus nothing has been done in any degree comparable to the vast enlargement which has thus been given to the sphere of human activity" Unfortunately, although the practicability of the scheme had been amply demonstrated and the engineering success was unquestionable, after about two months' work the communication failed—the conductivity of the cable was too low and the power applied to it was too high.

Then followed cables to the east—to Malta, Alexandria and India *via* the Persian Gulf, and it was not until 1865 that any further effort to lay a cable across the Atlantic was projected. In the meantime, Lord Kelvin had perfected his wonderful mirror apparatus, the progenitor of the syphon recorder, closer knowledge of the actual requirements had been secured and improvements in methods of manufacture developed. Also the paying-out and picking-up gear had been largely developed by Henry Clifford, and Brunel's great ship the *Great Eastern* was available to take the large core cable that Bright had succeeded in securing. By the end of 1866 there were two cables working across the Atlantic and the pioneers had about finished their part of the business. The next was routine—and skill combined with knowledge. Other cables followed, east and west; and then in 1872 commenced the great commercial achievements under Sir John Pender, which the Eastern Telegraph Companies are celebrating, after fifty years, with such justifiable pride.

International Chemistry.

THE International Union of Pure and Applied Chemistry held a successful annual meeting in Lyons on June 27-July 2 This was the third annual meeting and a good deal of time was, as on the former occasions, devoted to the details of organisation and the business of getting such an international body well established. Prof. Moureu has been president for three years and has had a difficult task in framing a policy for the score of nations who are now represented in the Union and in guiding them into harmony in these troublous times He has achieved his desire, and the Union seems likely to continue for many years and to have an increasing importance. It is intended, in the future to pay more attention to the purely scientific side of the subject and to attempt some discussions which will be of permanent value.

The Lyons meeting was well attended, about a hundred and twenty delegates, taking part, among whom may be mentioned Messrs Swarts and Timmermans (Belgium), Billmann (Denmark), Mourelo (Spain), Parsons, Bartow, and Washburn (United States), Grignard, Kestner, Marie, Moureu, and Perrin (France), Pope, Lowry, Hewitt, and Mond (Great Britain), Nasini and Paterno (Italy), Bodtker (Norway), Cohen, Kruyt, and Verkade (Holland), and Votoček (Czecho-Slovakia). Lyons is well provided with suitable buildings for the various meetings and social functions and there are many objects of interest in the vicinity. The commissions on nomenclature, publications, standards, food analysis, industrial hygiene, and international patents continued their work and presented interim reports. To carry out the recommendations of these commissions

requires more money than the International Union can provide, and a finance committee was appointed to allocate such funds as are available to those commissions the needs of which seem to justify the expenditure the most. It will be a case of the survival of the fittest, and the members of the finance committee, Messrs. Fraser (U.S.A.), Bertrand (France), Ponzio (Italy), and Miall (England) are not likely to be very popular with the members of the various commissions.

M. Kestner presided over the commission on international patents, a difficult problem which admits of no speedy solution. He has a plan for dealing with some of the defects of the existing system but proposes no universal panacea for all the inventors' troubles. Those who are interested in this thorny question might well communicate with him or the Société de Chimie Industrielle in Paris.

Interesting papers on purely scientific subjects were read by Profs. Perrin and Vignon.

Owing to the inability of some of the members to visit Lyons at this time the important Committee on the Elements which replaces the old International Committee on Atomic Weights did not meet. It is now meeting or has just met in Paris, and an authoritative list of atomic weights, isotopes, and other such data should be issued at a suitable interval after that meeting.

The Union elected as president for the ensuing three years Sir William Pope, and as vice-presidents for the same period Profs. Bancroft, Paterno, Billmann, and Votoček. It is probable that two additional vice-presidents will in due course be elected also, a proposal which is necessitated by the growing number of the countries concerned in the Union.

The next meeting will be held in Cambridge in the latter part of next June, and a considerable effort will be made to render this meeting one of real chemical importance. The French, who have been very prominent in the early stages of the Union, have done such good work in very difficult circumstances that it is felt that the English must, to maintain the tradition now that things are becoming a little easier, play their part in a manner which will be worthy of the ancient University which offers its hospitality and of the new president who will direct the proceedings of the meeting.

It is quite likely that the Society of Chemical Industry will hold its annual meeting next year in Cambridge immediately after the meeting of the International Union and a considerable migration of British and foreign chemists may be expected.

Radio Broadcasting in Great Britain.

DISAPPOINTMENT has been expressed at the delay in introducing radio broadcasting, arrangements for the establishment of which have been under discussion for some time past by the Postmaster-General and manufacturers of radio apparatus. The necessity, however, for the most careful and thorough examination of all aspects of the question is best illustrated by considering the present position of broadcasting in the United States. Radio broadcasting was commenced by the Westinghouse Electric and Manufacturing Co., for the information and entertainment of the public. Their success, however, produced a host of imitators, and broadcasting stations were established indiscriminately, some privately and some publicly owned. Only during the last few weeks has the United States Government taken action to co-ordinate and control indiscriminate transmission from radio-telephonic stations. When two broadcasting stations send out messages at approximately the same wave-length the electrical waves interfere with each other and the listener hears the conversation of two people speaking at the same time. It is not surprising to learn that the absence of a co-ordinating authority in the United States has resulted in a service which is unsatisfactory to the public owing to the lack of general agreement as to hours of operation, wave-lengths employed, and the character of broadcasted matter.

The British Government has wisely and properly decided that broadcasting licences will not be issued until those interested in carrying out this work are agreed on a scheme which will ensure, in the first place, efficiency and continuity of broadcasting, and, in the second place, agreement respecting hours of working, wave-lengths, number and location of stations, etc. Only in this way can confusion be prevented. Furthermore, the Government desires to prevent the broadcasting of advertising matter, in addition to having to safeguard the interests of newspapers and news agencies, Army, Navy, and Air Force work, commercial radio-telegraphy, etc.

We understand that about twenty manufacturers applied to the Postmaster-General for leave to broadcast, and during the preliminary discussions it became evident that the erection, equipment, maintenance, and operation of a proper broadcasting station costs approximately 20,000*l* per annum. A number of manufacturers therefore intimated their desire to abandon the idea of broadcasting, while about six of the strongest electrical concerns in the country interested in radio developments are prepared to continue. The manufacturers appointed a sub-committee to draft a scheme, and this committee reached agreement on all the main features of a broadcasting system for Great Britain. They were, however, unable to put forward an agreed scheme for one company to undertake broadcasting. It is now understood that the manufacturers have divided themselves into two groups, each of which is proceeding to form a broadcasting company, with one or other of which all manufacturers of radio apparatus would be associated. At the same time the Postmaster-General has intimated his willingness to give a licence to each of these companies to operate stations. The two groups between them undertake to establish a sufficient number of stations to serve the whole country. There will probably be one station belonging to each group in London and seven other stations distributed throughout Great Britain, divided between the two groups by mutual arrangement or, if agreement is not reached, by allocation of the Postmaster-General.

There is little doubt that details of working arrangements between these two groups will shortly be settled, and that broadcasting will be established on a basis which will give efficient and continuous service to the public without the hopeless confusion and lack of adequate control evident in the United States.

If each of the above nine stations is to have an annual cost of about 20,000*l*. per annum, the two broadcasting groups have to contemplate an outlay of 180,000*l* per annum. In order to assist the groups in securing an adequate return for this enormous outlay, it has been suggested to the Postmaster-General that a portion of the licence fees paid by users of receiving sets should be returned to the broadcasting groups. The groups represent between them the whole of the manufacturers of radio apparatus in this country, and their constitution is such that a genuine manufacturer must be admitted if he so

desires. The arrangement, therefore, does not exclude any genuine manufacturer, either now or in future, from playing his part in the business of manufacturing and selling receiving sets, and cannot therefore in any sense be regarded as creating a monopoly. Should the share of the annual licence fee paid to the broadcasting groups provide more money than is necessary to carry on the work, the licence fees could be automatically reduced.

Radio receiving apparatus lends itself particularly to manufacture abroad, in countries on the Continent where the depreciated exchanges make it possible to export receiving sets to this country at a price which would prohibit manufacture here. If this is allowed a promising new industry which will give employment to a very large number of people will be strangled before it has a fighting chance to succeed, and an opportunity of relieving distress arising from unemployment will be lost. Help for this industry, which may have ramifications far more important from the national point of view than the provision of entertainment or even methods of communication, may be given in some way. The Postmaster-General does not propose to license receiving sets unless made by members of one or other of the broadcasting organisations.

It is questionable whether manufacturers will be prepared to risk incurring the heavy expense attached to a broadcasting scheme if conducted in a proper manner, unless some assistance on the lines suggested can be provided. It is also not unreasonable to ask the public to assist in the cost of broadcasting, in view of the likelihood of providing programmes such as the following, which is typical of the best American stations.

"At six o'clock each evening, summary of important news, commercial, general, and sporting, followed at 7 P.M. by special addresses and lectures by business men and women. At 7.30 P.M. a bed-time or nursery story is provided for children, and at 8, for the remainder of the evening, a high-class musical programme comprising vocal and instrumental items or orchestral selections. Time signals are radiophoned at definite hours.

"On Saturdays the musical side of the programme is increased to include afternoon as well as evening performances. On Sundays church and chapel services and sermons are transmitted during morning and evening, with a Bible story for children during the afternoon.

"The lectures and music cover an extraordinarily wide range and appeal to all tastes, while the character of the broadcasted matter is varied and the quality is uniformly high. The tendency is to avoid transmission of gramophone music."

There will be nothing of interest to hear until broadcasting programmes are established, but a number of English stations can be set up very quickly once the preliminary discussions are completed and conditions of working settled, and there is reason to believe that by the autumn the country will be able to enjoy the best broadcasting in the world.

University and Educational Intelligence.

BANGOR.—Dr Edward Greenly has been appointed "Special Lecturer" in geology. Dr Greenly has for the last twenty years been engaged on a detailed study of the geology of Anglesey, and has recently published an account of his researches in a monograph "The Geology of Anglesey" (2 vols), which has been issued under the auspices of the Geological Survey. For this work, Dr. Greenly received the Honorary Degree of D.Sc. from the University of Wales. Dr. Greenly is now studying the Carnarvonshire coast. His appointment as "Special Lecturer" will enable him to direct the studies of advanced students who wish to work in this district, which is well suited for geological research.

EDINBURGH.—At the recent graduation ceremonies on July 21, science was represented in the list of Honorary Graduates in Laws by the following: Sir Isaac Bayley Balfour and Sir J. Halliday Croom, recently retired from their respective chairs; Prof. J. B. Farmer of the Imperial College of Science and Technology, London; Sir Thomas Middleton, formerly of the Board of Agriculture, Mr. J. W Mollison, late Inspector-General of Agriculture in India; M. Roger, Dean of the Faculty of Medicine of the University of Paris; Sir Charles S. Sherrington, Waynflete professor of physiology in the University of Oxford, and Dr. W. Somerville, professor of rural economy in the University of Oxford.

Dr. E. M. Wedderburn, known for his experimental work on seiches and for his services during the war as a meteorologist, has been appointed to the chair of conveyancing in the University.

LONDON.—Dr. J. F. Unstead, head of the geography department, Birkbeck College, has been appointed professor of geography in the University, in respect of the post held by him at Birkbeck College.

MANCHESTER.—The following have been awarded the degree of Doctor of Science: Mr. A. F. Campbell, for theses on (i) The influence of the introduction of the methyl group into the phenol molecule; (ii) The separation of phenol, ortho-, meta-, and para-cresols from crude coal tar and carbolic acids; (iii) A method for the preparation of β-naphthyl-amine: and seven other papers. Mr. J. N. Greenwood, for theses on (i) The constitution of copper-aluminium alloys; (ii.) Applications of optical pyrometry in steelworks practice; (iii) Heat flow of steel during ordinary processes of manufacture; and six other papers. Mr W A Harwood, for a memoir on upper air work in India. Mr. J. Holker, for a thesis on the periodic opacity of certain colloids in progressively increasing concentration of electrolytes, and twelve other papers. Mr. J. E. Jones, for theses on (i.) The distribution of energy in air surrounding a vibrating body, (ii) The velocity distribution function of the stresses in a non-uniform rarefied monatomic gas; (iii.) The kinetic theory of electrical conduction in an ionised monatomic gas, and three other papers. Mr. J. Pearson, for memoirs on (i.) The Holothurioidea of the Indian Ocean; (ii) Cancer, and a large number of articles and reports on biological work in Ceylon.

A PHYSICIST is required by the Research Association of British Motor and Allied Manufacturers for work as a senior research assistant. Applications are to be made by letter to the Secretary of the Association, 15 Bolton Road, Chiswick, W.4.

THE British Silk Research Association, Inc. (Kingsway House, Kingsway, W.C.2), invites applications for the appointment in its laboratory in Leeds of a chemist with research experience and special qualifications in physical chemistry. The latest date for the receipt of applications is August 11.

APPLICATIONS are invited for the position of a plant physiologist in the division of botany of the Department of Agriculture, Union of South Africa. Candidates must possess a University degree and have carried out research work in plant physiology. Applications, with particulars of education, qualifications and experience, etc., all in duplicate, must

reach the Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, W.C.2, not later than August 30.

A DIRECTOR of fisheries for Bengal is to be appointed shortly by the Ministry of Agriculture and Fisheries for a period of at least three years. Candidates are expected to have a first-class knowledge of marine biology, and practical experience in fishery work Further particulars may be obtained from the Fisheries Secretary, Ministry of Agriculture and Fisheries, 43 Parliament Street, London, S.W.1, to whom all applications, accompanied by not more than six testimonials, should be addressed by, at latest, August 20.

Two research scholarships in veterinary science, each of the annual value of 200*l* and tenable for three years, are being offered by the Ministry of Agriculture and Fisheries. The scholarships are open to candidates who have obtained the diploma of the Royal College of Veterinary Surgeons, or who have shown evidence of proficiency in medicine or other relevant branch of science. Applications will be received until August 15 on the prescribed form, of which copies may be obtained from the Ministry at 10 Whitehall Place, S.W 1

THE prospectus for the year 1922–23 of the Technical College, Bradford, contains very complete accounts of the courses of study offered by the College. Diploma courses, which involve full-time attendance for three or four years, are arranged in the departments of civil, mechanical, and electrical engineering, textile industries, chemistry, dyeing, and occasionally in biology. These courses are suitable for students desirous of presenting themselves for the honours examinations of the University of London. There are also special day courses in these departments, and preparation is given for the professional examinations in medicine, dentistry, and pharmacy. Part-time day courses are arranged in various subjects which are suited to the needs of apprentices and others who are unable to devote the whole of their time to study. The prospectus gives particulars of the conditions for the admission of students, and there are also detailed syllabuses of the various courses.

THE Ramsay Memorial Fellowship trustees have made the following awards: Ramsay Fellowship of the value of 300*l*. tenable for one year, but renewable for a second year, to Dr. R W. Lunt, of the University of Liverpool, and of University College, London, for the continuation of his work at University College, London, on chemical effects of electromagnetic waves over the frequency range, 10^6 – 10^8 cycles, Glasgow Ramsay Fellowship of 300*l* to Mr J A Mair, of the University of Glasgow, who will continue his research on the chemistry of the terpenes; a special Fellowship of 300*l* for one year to Mr W Davies, who has already held a Ramsay Fellowship for two sessions and whose work, especially that on the preparation of synthetic reagents from the toluic acids, shows special promise; Danish Ramsay Fellowship to Mr. Kristian Hoejendahl, of the University of Copenhagen, who will pursue his research in the University of Liverpool; two Swedish Ramsay Fellowships, to Dr J O G. Lublin and Mr A. W Bernton, and two Norwegian Ramsay Fellowships to Mr Dag Nickelsen, who will work at the Imperial College of Science and Technology, and Miss Milda Prytz, who will work at University College, London. A special Ramsay Fellowship of the value of 350*l*, which was placed at the disposal of the National Research Council of the United States of America, has been awarded to Dr. C. S Piggot, of Baltimore, who will begin work at University College, London, in October.

Calendar of Industrial Pioneers.

August 7, 1834. Joseph Marie Jacquard died.—A native of Lyons, which he helped to defend against the armies of the Convention in 1793, Jacquard was a weaver by trade Becoming known for his ingenuity and his attempt to construct lace-making machines, he was employed by Carnot at the Conservatoire des Arts et Métiers, and on December 23, 1801, he patented his well-known loom for weaving figured materials. Though like Arkwright he met with much opposition, Napoleon in 1806 granted him a pension of 6000 francs and a premium on each loom erected.

August 7, 1913. Samuel Franklin Cody died.—Accidentally killed when flying at Aldershot, Cody was one of the most enthusiastic of the early fliers and was the designer and constructor of the machines he flew. Born in 1861 in Birdville, Texas, after a somewhat chequered career he gained a reputation by his experiments with kites, and in 1906 was appointed chief instructor in kite-flying to the British Army.

August 7, 1747. Martin Triewald died.—A promoter of industrial progress in Sweden, Triewald was born in Stockholm He spent some years in England as manager of a coal mine at Newcastle, and on his return to his native country introduced the use of the Newcomen atmospheric engine.

August 8, 1873. Sir Francis Ronalds died.—One of the pioneers of the electric telegraph, Ronalds was the son of a London merchant Born in 1788, he was early engaged in scientific pursuits, and in 1816, in the garden of his house in Hammersmith, laid down eight miles of wire through which he sent signals by the aid of a small frictional machine. From 1843 to 1852 he was honorary director of the meteorological observatory at Kew.

August 10, 1896. Otto Lilienthal died.—After achieving success as an engineer and manufacturer, Lilienthal in 1889 began his experiments in flight. With machines of his own construction he made many long gliding flights from the top of an artificial mound nearly 100 feet high at Lichterfelde, and it was while pursuing these experiments that he met with the accident from which he died.

August 12, 1848. George Stephenson died.—Recognised as the father of our railway system, and as the chief pioneer of the locomotive, Stephenson built his first successful locomotive in 1814 while engine wright at Killingworth Colliery. For the Stockton and Darlington Railway he constructed and drove the *Locomotion* with which the line was opened in 1825, and four years later achieved a notable success with the *Rocket* constructed for the Liverpool and Manchester Railway. Stephenson was engineer to both of these lines and was afterwards engineer also to the London and Birmingham, the Manchester and Leeds, the Manchester and Birmingham and other important railways He was the first president of the Institution of Mechanical Engineers, founded in 1847

August 13, 1897. Sir Isaac Holden died.—Born near Paisley in 1807, Holden at the age of ten began work in a cotton mill From a shawl weaver he became a school teacher and then a book-keeper for a Glasgow worsted firm. Turning his attention to invention, with Lister (afterwards Lord Masham) in 1847 he took out a patent for combing and preparing genappe yarn and founded a factory at St. Denis, Paris. He afterwards concentrated his business at Bradford, where it became the largest woolcombing concern in the world

E. C. S.

Societies and Academies.

PARIS.

Academy of Sciences, July 3.—M. Emile Bertin in the chair.—The president announced the death of Prince Albert of Monaco, foreign associate of the Academy.—P. A. **Dangeard**: The structure of the cell in the Iris. In a recent communication the author has given a detailed description of the plastidome and spherome in the leaves of *Iris germanica*: this is supplemented in the present paper by similar details for the same formations in the tissues, petals, sepals, stamens, ovary and ovules. The plastidome and spherome are independent formations and have an existence as general as the nucleus in the plant cell.—André **Blondel**: The unsymmetrical electric arc between carbon and metals.—M. Albert Recoura was elected correspondant for the section of Chemistry in the place of the late M. Ernest Solvay.—The Permanent Secretary announced the death of M. Otto Lehmann, correspondant for the section of Mineralogy.—Armand **Cahen**: Singular solutions of differential equations of the first order.—Miécislas **Biernacki**: The displacement of the zeros of integral functions by derivation.—R. **Jarry-Desloges**: Contribution to the study of the surface of planets. The systematic observation of the planetary surfaces, especially of Mars, commenced in 1907 at Revard, have been continued in May and June of this year at Sétif, with the 37 cm. and 26 cm. refractors. The decoloration of certain dark areas in the southern hemisphere of Mars, observed in 1909 at Revard, has been seen again this year.—Jules **Baillaud** and Mlles. **Bonnet**, **Clavier**, and **Lhomme**: Distribution of stars in the Paris zone of the astrophotographic catalogue.—Axel **Lindh**: The absorption spectrum of sulphur for the X-rays. An examination of sulphur compounds grouped according to the valency of the sulphur. As in the case of chlorine previously studied, the limits of the K absorption for sulphur are displaced towards the shortest wave-lengths for the higher valencies.—Albert **Portevin**: The thermal treatment of cast pieces, and especially of cast projectiles. Thermal treatment produces porosity in the metal.—Roger G. **Boussu**: The limit of inflammability of the vapours of the alcohol-petrol system and of a triple system containing as base alcohol and petrol.—C. **Matignon** and M. **Fréjacques**: The transformation of gypsum into ammonium sulphate. Calcium sulphate was stirred with concentrated ammonium carbonate solution in approximately equimolecular proportions. Equilibrium was reached after five hours, about 96 per cent. being converted into ammonium sulphate.—Albert **Granger** and Pierre **Brémond**: The chemical composition of rock, supposed to be kaolin, from Djebel Debar, Algeria. This is formed of halloysite, associated with a hydrated aluminium silicate containing combined sulphuric acid.—Paul **Thiéry**: The upper Bajocian of Lorraine.—G. **Denizot**: The last variations of the marine level on the coasts of Basse-Provence.—P. **Bugnon**: The basifuge acceleration in the hypocotyl.—G. **Nicolas**: A new host of Phyllosiphon. This parasite was found on *Arum italicum* near Toulouse. This resembles *P. Arisari*, and if not belonging to a different species, constitutes a different biological strain, since although *Arisarum vulgare*, carrying *P. Arisari*, grows in the neighbourhood of *Arum italicum* in Algeria, the latter plant has not been found attacked by the parasite.—Pierre **Lesage**: Experiments on the movement of liquids in cell masses.—Jacques **de Vilmorin** and **Cazaubon**: The catalase of seeds. The presence of catalase cannot be taken in all species as a proof of the vitality of the seed.—Marc **Romieu** and Fernand **Obaton**: Comparative spectroscopic study of the green pigment of the Chetoptera and the chlorophyll of the green alga, *Ulva lactuca*. The chetopterin is regarded as a pigment of extrinsic origin, and is a modified chlorophyll.—Mme. **Danysz-Michel** and W. **Koskowski**: Study of some digestive functions in normal pigeons, fed with polished rice or kept without food. Comparative experiments made with pigeons on four different diets: normal diet, no food, polished rice only with and without daily injection of histamine. From the examination of the gastric juice and intestinal contents it is concluded that the observed facts can be explained without assuming the intervention of a vitamin.—J. **Athanasiu**: Nerve motor energy: electromyograms.—L. **Garrelon**, D. **Santenoise**, and R. **Thuillant**: The action of peptonic shock on the vago-sympathetic nervous system.—P. **Wintrebert**: The first manifestations of nervous co-ordination in the body movements of *Scylliorhinus canicula*.—Pierre **Girard**: Remarks on a note of M. L. Lapicque on the mechanism of the exchanges between the cell and the surrounding medium.—W. R. **Thompson**: The theory of the action of entomophagous parasites. Increase in the proportion of hosts carrying parasites in cycle parasitism.—S. **Metalnikow**: An epizootic disease in the caterpillars of *Galleria mellonella*.—R. **Cambier** and E. **Aubel**: The culture of bacteria in a medium of definite chemical composition, with pyruvic acid as a base. The degradation of pyruvic acid. In these cultures the only source of carbon is sodium pyruvate. Three bacilli could be grown on this medium, the pyocyanic bacillus, Flugge's fluorescent bacillus, and the coli bacillus. Acetic, lactic, and glycollic acids were isolated from the cultures.

NO. 2754, VOL. 110]

Universities of Oxford and Cambridge Bill.

WHEN some three years ago the Universities of Oxford and Cambridge applied to Parliament for an annual grant to meet recurring expenses it was obvious that such aid could be given only after due inquiry. Accordingly a Royal Commission was appointed on November 14, 1919, "to enquire into the financial resources of the Universities and of the Colleges and Halls therein, into the administration and application of those resources, into the government of the Universities, and into the relations of the Colleges and Halls to the Universities and to each other." On March 24 of the present year the report of this commission was published, and as a direct result we have the Bill which was introduced by Mr. Fisher, president of the Board of Education, into the House of Commons on July 24.

The Bill is short, consisting of ten sections, with a schedule embodying certain provisions of the Universities of Oxford and Cambridge Act, 1877, adapted for present purposes. Two bodies of commissioners are to be set up, styled respectively "The University of Oxford Commissioners" and "The University of Cambridge Commissioners." The commissioners are named and comprise men representative of the varied aspects and interests of university life. Their tenure of office is temporary and will normally expire at the end of the year 1924, but may on the application of the commissioners themselves be continued by His Majesty in Council for other two years. From and after January 1, 1924, these commissioners will "make statutes and regulations for the University, its colleges and halls, and any emoluments, endowments, trusts, foundations, gifts, offices, or institutions in or connected with the University in general accordance with the recommendations contained in the Report of the Royal Commission, but with such modifications as may, after the consideration of any representations made to them, appear to them expedient."

After the termination of the powers of the commissioners the universities and colleges will again assume their own government, but notice of any proposed statute for a college must be given to the university before it is submitted to His Majesty in Council, and any college statute which affects the university may not be altered without the consent of the university. Again, except with the consent of the trustees or governing body, no trust may be altered "unless fifty years have elapsed since the date on which the instrument creating the trust came into operation." This, however, will not operate against increasing the endowment of any emolument. Further, the contributions of the colleges to university purposes must be assessed in

the first place with regard to the needs of the colleges themselves.

The schedule deals with such questions as the interim powers of the universities and colleges; the provision that the commissioners in framing statutes "shall have regard to the interests of education, religion, learning, and research; the election of college representatives as commissioners; and procedure generally and other matters of detail.

Obviously the Bill must be read in the light of the Report. The institution of two bodies of commissioners is the result of a recommendation in it "that a Statutory Commission should be set up to carry out the changes recommended," and the powers of these two bodies are defined, except in special circumstances, by it. As we have remarked in a previous article in these columns the Report is distinctly conservative. Similarly, the Bill, for example in its provision for dealing with trusts and endowments, shows clearly that there is no intention of making sweeping changes. The new commissioners hold office for a season; the suspension of the autonomy of the universities is merely temporary.

The new bodies have no easy task before them. The problems will demand knowledge, skill, and tact. The question of the reform of the government of the university requires delicate handling. The colleges must be brought into closer relationship with the university. The teaching will have to be reorganised and co-ordinated, and proper provision made for research and advanced work. Fellowships, scholarships, extra-mural education, cost of living in colleges, non-collegiate students, and entrance examinations are some of the questions to be dealt with. In addition, there are the twin problems of salaries and pensions. Here it may be expected there will be difficulties. Notwithstanding all that has been done in recent years in the modern universities these are problems still unsolved there. The question is not an easy one. For the Cambridge Commission there is the further question of the position of women in the university.

The projected reforms can be effected only by a large increase in the income of the two universities. The Report recommends an annual Parliamentary grant of 100,000*l.* to each university. Such a sum is none too great for carrying into effect its financial proposals. At present the grant is 30,000*l.* to each, and doubtless a further instalment in the immediate future is contemplated. This raises the important question as to whether or not Oxford and Cambridge should have separate and individual consideration in the matter of State aid apart from the modern universities. In some respects it is right and proper that separate and individual consideration should be given to these ancient institutions, particularly if due respect is to be paid to the conservation of the best of their traditions. But the case is not on all fours where finance is concerned. Until recently the modern universities had been treated somewhat scurvily by the State, and even now they receive only 1,200,000*l.* of an annual Parliamentary grant for allocation among something like sixty institutions. The largest individual grant for the year 1921–2—that received by the Imperial College of Science and Technology—amounts to 67,500*l.*, a sum in our opinion quite inadequate for the expansion and development of an institution of this standing. Moreover, when the amounts allotted to the other institutions of university rank are considered in detail, it is clear that a sum of 200,000*l.* for Oxford and Cambridge is quite out of proportion. The modern universities are not receiving the financial help from the State to which they are entitled, and, in particular, at the very time when Oxford and Cambridge are receiving for the first time an annual grant of 60,000*l.*, they are being deprived of an annual grant of 300,000*l.* This withdrawal cannot be justified. In point of fact the financial difficulties of the modern universities are equally as great as, if not greater than, those of the two older universities.

The question of Parliamentary grants to our universities should be considered as a whole and not piecemeal. In the light of seemingly contradictory statements made in public regarding State aid given to the modern universities it would appear that the whole question should be discussed in Parliament. It is not true, except as a mere technicality, to say that the annual grant to the modern universities will remain at its present level. Any one who takes this statement at its face value will have a rude awakening in the coming financial year. In our opinion, in such circumstances, it would be a mistake to consider the financial needs of Oxford and Cambridge apart from those of the modern universities. The position of the whole of the universities in the United Kingdom should be considered together, and not simply the position of two of them however ancient and honourable their traditions.

Paracelsus.

Theophrastus Bombastus von Hohenheim, called Paracelsus: His Personality and Influence as Physician, Chemist, and Reformer. By Prof. J. M. Stillman. Pp. viii+184. (Chicago and London: The Open Court Publishing Co., 1920.) 10*s.* net.

As is well known, it is the customary lot of revolutionaries, whether in politics, religion, literature, or science, or indeed in any department of intellectual activity, to be both vilified and extolled, and the

praise and the blame are usually administered in very unequal measure, and with no due regard to the intrinsic merits of the recipient. The common instinct of mankind is to oppose change, and he who sets himself athwart the general tendency to consider whatever is is right is certain to reap abuse for his pains, and to have his motives, however well meant, misrepresented and traduced. History shows that most reformers are in advance of their age. It is rarely that they hit what is mistakenly called the psychological moment—that is, when the world is ripe for the change they advocate, and willing and even eager to see it effected. In this exceptional case the reformer is extolled, his service universally acclaimed, and his immediate fame assured. The pioneer who has to face the *vis inertiae* of his age may, and usually does, go down to his grave "unwept, unhonoured, and unsung." It is only when the fermenting leaven he has laboured to introduce has, it may be after many years, produced its effect, that his effort is recognised and its results appreciated.

Such was the fate of him who is the subject of the work under notice. No man of his epoch was so systematically and so consistently disparaged, abused, and reviled as Theophrastus von Hohenheim, commonly called Paracelsus. His true vocation was that of a medical practitioner, and the head and front of his offending was that he should have striven to enlarge the scope of the medical system of his time—not simply by opposing the time-honoured doctrine of Hippocrates and Galen, as authorised by all the medical faculties of the period in every University of Europe—but by seeking to graft on to it newer conceptions and a wider and more rational scheme of therapeutics.

Paracelsus is frequently regarded as a chemist, and he certainly has his place in the history of chemistry. But he made no cardinal discovery in that science, and his name is not associated with any process or apparatus in operative chemistry. He wrote no treatise exclusively concerned with chemistry. He led a restless wandering existence, travelling, according to his own account, over nearly the whole known world, picking up and mentally storing the medical *arcana* of the various countries he traversed.

During the forty-eight troubled years of his chequered life Paracelsus certainly acquired a considerable knowledge of the chemical arts of his time; he writes familiarly of certain chemical processes, and shows acquaintance with the properties and uses of a fairly wide range of manufactured products. His great service to chemistry was that he was among the earliest to point out that the work of the professed chemists of his epoch was on wholly wrong lines. The ostensible objects of alchemy were illusory. In conceiving the possibility of transmutation the alchemists were imagining a vain thing. The true and proper function of the chemist was to serve humanity by preparing and studying the properties of substances of natural and factitious origin with a view of applying them in the treatment and cure of disease.

By thus creating the school of iatro-chemistry Paracelsus enlarged greatly the field of chemistry and extended enormously the scope of its operations. But, strictly speaking, Paracelsus only reverted thereby to the practice of the Arabian followers of Galen—Avicenna, Averrhoes, and their immediate followers—who taught that chemistry was the true hand-maiden of medicine. Their precepts had been misinterpreted and corrupted by a succession of commentators—mostly scholastics—who had imported into their teaching a leaven of mysticism and occultism altogether foreign to the spirit of Galen. Erasmus said of the medical system of his time that the whole art as they practised it was but an incorporated compound of craft and imposture.

The reform of medicine was part of the general movement of the Renaissance, and Paracelsus was as much a product of the period as Leonardo da Vinci, Copernicus, Thomas More, Luther, Vesalius, and the other progenitors of that great awakening. He created not only a new departure in chemistry, but he infused a new spirit into medical teaching and practice, and his reward was to suffer the slings and arrows of outrageous fortune in obloquy, poverty, and occasional starvation. He was fighting against the *Zunftgeist* of his age, against powerful corporations and strongly entrenched vested interests. Although he fell in the unequal struggle he was not beaten, for the spirit he invoked lived after him and eventually triumphed.

Paracelsus was a highly complex character—a strange compound of genius and folly, of ill-regulated life and unstable habits. It is this complexity of nature which is doubtless at the basis of the very divergent estimates which his various biographers have formed of him. He had all the defects of his qualities, and to a great extent he brought his misfortunes upon himself. He was of a rash, unbalanced disposition, impetuous, impatient of contradiction, a hard-hitter, and prone to intemperate language. Of course, he was stigmatised as a quack and a charlatan, and it must be admitted there were incidents in his career which afforded ground for the imputation. He seems to have treated the reproach with a contemptuous indifference which afforded no sufficient answer to his adversaries and no real satisfaction to his few followers and friends.

In spite of much that has been written concerning him Paracelsus remains an enigma, and his memory still suffers from the obloquy which was heaped upon

him during his life. Of late years there has been a tendency to seek to do him fuller justice and to put a more liberal and more kindly interpretation upon his conduct and actions, and to place him in what is to be regarded as his true relation to his epoch. Prof. Stillman's book is the latest attempt at his rehabilitation. It is a scholarly contribution to a subject which has still its perplexities and difficulties. The story of his life is here told without bias, dispassionately, and in the light of all available information, and the result is an eminently readable monograph written in the true spirit of history.

T. E. THORPE.

The History of British Agriculture.

(1) *English Farming: Past and Present.* By the Rt. Hon. Lord Ernle. Third edition. Pp. xvi + 504. (London: Longmans, Green and Co., 1922.) 12s. 6d. net.

(2) *A Short History of British Agriculture.* By John Orr. Pp. 96. (London: Oxford University Press, 1922.) 2s. 6d. net

(1) THE story of British agriculture is for the greater part of its course the story of the life of the ordinary Briton, for until the industrial and commercial era began a century ago the country was in the main agricultural Several histories have appeared, but none is more attractive than the volume written by Lord Ernle, which has now reached its third edition. There are few records of actual farming prior to the Norman invasion, and the account here given begins practically in the thirteenth century, though there is no reason to suppose that any great change had been brought about in agricultural methods for a long while previously. From that time onwards, however, the story is continuous, though it has had to be pieced together from manorial records, old country sayings, illuminated MSS., and many other sources Lord Ernle has done his work remarkably well, and he traces with great clearness the changes from the old open field system, through the enclosures of the sixteenth, seventeenth, and eighteenth centuries, to the great changes introduced in the nineteenth century, and finally to our own times.

The edition before us differs from the previous one in that it contains a chapter on war farming in 1914–1918. This was an essay in State control, and the measure of its unpopularity in the countryside was seen in the almost savage joy with which the wholesale retrenchment of the numerous inspecting officials after the war was hailed, and in the irresistible demand for the removal of all restrictions on freedom of cropping and of farm management. Whatever the urban voter may elect to bear in the way of State control of industry, it is perfectly certain that the countryman will have none of it: he is an incorrigible individualist.

Space does not allow of an adequate quotation from the account of the history of those eventful days. Lord Ernle has the double advantage of inside knowledge and of freedom from any restriction in relating the course of events, and he tells the story vividly. The real agricultural difficulty began in 1917, after the harvest of 1916. The Board of Agriculture had foreseen this and had prepared a scheme, but the Cabinet had not put it into operation. The winter 1916–17 was very unfavourable to the agriculturist; the supply of men, of feeding-stuffs and of fertilisers was short, and was diminishing, and farmers generally were losing heart. State control became imperative. The method adopted was probably as good as could be devised, and very full powers were given to the large body of experts brought in for the purpose. In spite of all its disadvantages and the increasing difficulties in regard to labour and materials, the system was successful in producing certain items of human food, as the following table proves:

Crops	1918	1916	1904-13	Increase Over 1916	Increase Over 1904-13	Percentage of Increase Over 1916	Percentage of Increase Over 1904-13.
(In Thousands of Quarters)							
Wheat	10,534	6,835	6,653	3,699	3,881	54	58
Barley	6,055	5,181	6,212	901	127	17	2
Oats	14,336	10,411	10,572	3,925	3,704	38	36
Mixed Corn	*620	*	*	620	620		
Beans and Peas	1,328	1,122	1,529	206	-201	18	-13
Total	32,903	23,519	24,966	9,354	7,937	19	32
(In Thousands of Tons)							
Potatoes	4,209	2,505	2,643	1,704	1,566	68	59

The present writer can testify, however, that the machine was kept going only by constantly reminding the rural community of the men in the trenches, and had it not been for the poignant sorrow and bitter tragedy of the war no power on earth would have kept the farmers to the programme. It is not that they are less patriotic than others, quite the contrary. But the system is not suited to the conditions of the countryside and so it lacks permanency. Post-war agriculture is adjusting itself to post-war economic conditions.

The volume is full of interest and will certainly appeal to a large body of readers.

(2) Teachers of agriculture generally will welcome the appearance of a little book on the history of the subject which they can place in the hands of their students, in the first instance to stimulate their interest, and afterwards as an introduction to larger works.

* Mixed corn is shown separately in 1918. In previous years it is shown under wheat, barley, or oats.

Mr. Orr's book can confidently be recommended for this purpose.

The book is simply written and can be read without any extensive knowledge of English history: it is unbiassed and, for its size, it gives as good an account as we have yet seen of the course of events in British farming from the earliest times to the present day. The illustrations are excellent and well chosen from a wide range of sources: they show, side by side, the older and the newer types of implements or of animals, and afford admirable demonstrations of the great changes that have taken place since agriculture began to develop.

In discussing the post-war period Mr. Orr ends on a note of subdued optimism which we hope and believe is justified: "The market for farm produce is weak. Agriculture must share the bad fortune as well as the good fortune of the country and even of the world. In view of the magnitude of the war its evil effects will probably be very great and very prolonged. But however difficult times may be, there is promise for the future in the better feeling that exists between landlords and tenants, employers and employed, as compared with that which prevailed a century ago. There has been no poor-law payment of wages, and the difference between the treatment of the labourer then and now is an indication of the progress that has been made."

E. J. Russell.

Ore Deposits.

Abriss der Lehre von den Erzlagerstatten: In Anlehnung an die dritte Auflage des Lehrbuches und unter Benutzung hinterlassener Aufzeichnungen. Von Prof. Richard Beck. Bearbeitet durch Georg Berg. Pp. xi + 438. (Berlin: Gebruder Borntraeger, 1922.) 16s. 8d.

As is stated by Dr. Berg in his introduction, this work, an abstract of the study of ore deposits, is an abbreviation of the large work in two volumes by Richard Beck. The original work was well known, and three editions have been published since it was originally issued in 1900. The general principle of classification remains nearly the same as that in the original work, and it must be admitted that, generally speaking, the changes that have been made have not made for a clearer understanding of this exceedingly complex subject.

As in the original, a clear cut is made between epigenetic and syngenetic deposits; the author defines these phrases as follows: in the former he includes deposits into which ore has been introduced only after the formation of the immediately adjoining country rock, while the latter term is restricted to magmatic segregation in which the ore is formed simultaneously with the country rock. These basal definitions, however, are by no means satisfactory. The author's definition excludes from the syngenetic group sedimentary deposits, such as beds of ironstone deposited originally as bog ironstone, etc., and in fact Dr. Berg has treated such deposits quite separately from his syngenetic deposits and has placed them in his classification after the epigenetic deposits. Dr. Beck, on the other hand, looked upon such ores as syngenetic, and there is no doubt that his view is the sounder and leads to a clearer understanding of the entire subject.

Again, Dr. Berg devotes a separate section to the Gozzans or alteration products of existing ore deposits, formed above permanent water level, which may include both secondary enrichment and impoverishment of the deposits in respect of their metallic contents. He classifies these deposits as epigenetic on the grounds that certain deposits are in themselves not worth working except in the zone of secondary enrichment; perhaps, strictly speaking, there is something to be said for this argument, but it certainly does not make for a clear understanding of the subject. If distinctions are to be drawn between the deposit itself and its more or less altered outcrop, confusion is bound to result. In fact, one of the great faults of the work lies in the author's failure to appreciate that in dealing with such phenomena as ore deposits, where a natural system of classification is practically impossible, broad lines must be followed; even so, there will be numerous border cases which every student of the subject will treat on somewhat different lines. One of the most striking points in the book, which well illustrates what has just been said, is the minute subdivision of mineral veins based upon differences, and sometimes small differences, in their mineral contents. In this Dr. Berg has followed Dr. Beck, the need for simplification apparently not having occurred to him. The whole of the treatment of mineral veins may be described as somewhat antiquated, seeing that over one-third of the work is devoted to fissure veins. This diffuse treatment is reminiscent of the days when the overwhelming proportion of all metallic minerals (with the exception of iron ores) was derived from fissure veins, as was the case a century ago. To-day, on the other hand, the output from veins is relatively unimportant, and the author does not seem to have realised how great the change has been in this respect.

The author divides his subject into the following main groups:

I. Magmatic segregations.
II. Contact deposits.
III. Mineral veins.

IV. Epigenetic ore bodies.
V. Sulphuretted ore deposits mainly of epigenetic origin.
VI. Ores formed by sedimentation.
VII. Gozzans.
VIII. Secondary (clastic) deposits.

Many of these groups are by no means satisfactory, inasmuch as the deposits included in them do not properly correspond to the titles given. Thus the author quotes as examples of magmatic segregation the magnetites in gneiss of the Lofoten Islands and the Kiruna ore, although he admits that the latter ore deposit is definitely younger than the adjoining eruptive rocks and accordingly not syngenetic with these. Similarly he includes among contact deposits, by which he understands those formed under the influence of contact metamorphism at or near the boundaries of the eruptive and the stratified rock masses, a number of deposits as to which he is bound to admit that he cannot ascribe their origin to any particular eruptive rock. He describes those as krypto-contact deposits, but obviously such a description is far from satisfactory. Among his epigenetic ore bodies he includes such deposits as those of Bingham and Bisbee, where the protore is undoubtedly syngenetic, gash veins and similar deposits in pre-existing cavities, true metasomatic deposits like the red hæmatites of Cumberland, and certain residual deposits, while his group of sulphuretted ore bodies is admittedly not a natural entity and contains examples of syngenetic, epigenetic, and indeterminate modes of origin. This method of dealing with the subject creates confusion rather than clearness; it is conglomeration, not classification.

There are various mistakes in geography, which should have been avoided, for example, the Sierra de Ronda is said to be on the Portuguese coast, and Leadville in England! Moreover, the work aims at describing every deposit of importance, but there are several notable omissions.

No doubt there is room for a good, small text-book on mineral deposits, but it will have to be on different lines from those of the present one; more care will have to be devoted to classification and to the discussion of the modes of formation of the deposits, and fewer examples, and those only typical ones, must be quoted, references to descriptions of others being generally sufficient. It is probably only in this way that the student can get a clear view of this complex subject. The work at present before us does not fulfil these conditions; it may be of use for reference to the experienced mining geologist who is not likely to be led astray by it, but it is scarcely a safe book to place in the hands of a beginner.

H. LOUIS.

The Living Soil.

Das Edaphon: Untersuchungen zur Ökologie der bodenbewohnenden Mikroorganismen. Von R. H. Francé. Zweite Auflage. Pp. 99. (Stuttgart: Franckh'sche Verlagsbuchhandlung, 1921.)

"EDAPHON" is the name which, from their analogy to the plankton, Dr. Francé has coined to cover all the forms of life occurring in the soil. In spite of the very considerable amount of work that has been done in recent years on these organisms, very little of it is at present available to the general biological reader. There are text-books of agricultural bacteriology and a considerable number of scattered papers dealing with single organisms or groups of organisms from the soil, but most of these reach only the specialist. Dr. Francé has therefore performed a real service in writing a brief general account of the soil fauna and flora, its conditions of life, and the influences of the different groups of organisms on one another and on the soil.

As a general handbook to the subject, however, it suffers from one considerable defect, for during the past few years great advances have been made both in this country and in America, of which apparently Dr. Francé has as yet heard nothing, since he gives no references to any non-German work of a later date than 1912. Even a casual glance through recent numbers of the English and American journals would not only have given him many useful facts, but would also have suggested methods of technique which would have made his own investigations much more fruitful. His accounts in particular of the insects and flagellates give very little idea of the number and variety of these creatures occurring in the soil.

The observations on the ecology of the organisms would also have been more satisfactory if a little more statistical information had been given. It is not very useful to be told that in May a cubic millimetre of soil contained 15 organisms (omitting bacteria), whereas in August the number had fallen to 3, unless we are also told how much variation there is between duplicate samples taken at the same time or at brief intervals. Since Dr. Francé frequently reminds us of the close analogy between the edaphon and the plankton, one naturally recalls the wide divergences found in duplicate catches of the latter. Probably he is right in believing that the figures given are significant, but the reader who wishes to understand what are the effects of temperature, moisture, season, and the physical and chemical properties of the soil on the organisms living in it, is at a great disadvantage if he is not told just what is the degree of significance.

In spite of these defects, however, the present

volume contains a great many useful observations and a very lucid and stimulating review of the subject. One may question whether the biological influences have quite the dominating importance in the soil that is here claimed for them, and in particular whether the organisms found in it can as yet be satisfactorily used as a criterion of the agricultural properties of a soil; but the subject is still young and its possibilities are undoubtedly great.

The Presentation of Thermodynamics.

Vorlesungen über Thermodynamik. Von Prof. Dr. Max Planck. Sechste Auflage. Pp. x + 292. (Berlin: W. De Gruyter und Co., 1921.)

ONE of the most universal generalisations that can be made about the study of mathematical physics is that everybody finds thermodynamics a very difficult subject. In consequence of this there have arisen several different ways of presenting it, which vary far more from one another than do the presentations in such subjects as dynamics or electricity. There is first the thermodynamics of the engineer, in which entropy is something steam has, which can be found from tables. Then there is the thermodynamics of the chemist, whose laboratory is stocked with semi-permeable membranes. He is a great designer of engines, but all his enjoyment of his wonderful instruments is spoiled by his perpetual suspicion that Nature is trying to score off him. Next, there is the thermodynamics of the mathematician; this scraps the chemist's machinery and does the whole business by means of Pfaffian forms, a peculiar branch of mathematics, and almost the only one in which it looks as if more comes out at the end than is put in at the beginning. Lastly, there is the super-man, who can see and count the atoms, who regards all the others as gamblers, though he is bound to admit that they know how to lay the odds. He occupies a position rather apart, being, so to speak, engaged in a study of the jurisprudence of thermodynamics.

Now (excepting the last), all these presentations claim to derive their results from the two laws of thermodynamics, but there is no agreed statement of those two laws. In most books the chapter on the Second Law is not opened by a formal statement of that law—as Newton's laws of motion would head the corresponding chapter in a book on dynamics—but it is necessary to have several pages of tendencious discussion first, to create the atmosphere in which the law shall be acceptable. This can only mean that the law as stated contains a good many implied assumptions. Some years ago Carathéodory, the pure mathematician, formulated the principles in a really logical manner, and it is to be hoped—if we can believe that the human mind is by taste rational—that this formulation will be more successful in making the subject easy than has the exceptional variety in presentation which has hitherto prevailed. Carathéodory's work was transcribed a year or two ago in the *Physikalische Zeitschrift* by Born. He insists that there is no way of shirking the Pfaffian problem in some form or other, but gives a simple geometrical description of it; in the consequent deduction of absolute temperature and entropy there is some rather heavy work which could probably be simplified. But the most important modification is the new place taken by temperature in the presentation. In the ordinary way it occurs muddled up with the Second Law, but here it is taken out and introduced as the primitive idea—of course, measured on an arbitrary scale. The consequence is that the First Law no longer deals with quantities which are undefined, and the Second Law becomes a clear-cut statement instead of a jumble of two statements.

The new presentation is too recent to have been adopted in text-books, and it will be most interesting to see whether it is destined to drive out the older types. The book under review is of a class about midway between those of the chemist and those of the mathematician. That it has gone through six editions shows that it is a first-rate introduction to the subject; but it certainly can be criticised from the logical point of view, for it brings in absolute temperature by means of the perfect gas, and only later justifies it in the general case. It is a philosophical question whether it is legitimate to introduce ideas connected with reality by means of a hypothetical substance—perhaps it may be defended, like the introduction of rigid bodies in dynamics. But the point really is that this method is apt to leave the student with the idea that absolute temperature is in some way connected with perfect gases, an idea rather encouraged by many of the examples that are usually cited. It is surely a pity to start by dealing with a special case, when the whole argument is that Carnot's cycle works exactly as well whatever the substance in the cylinder. Apart from this criticism, however, the whole work is an admirably detailed development of the theory, with numerous illustrative examples from physical chemistry. The chief changes in the new edition are in connexion with the theory of solutions; in particular, an account is given of the theory of J. C. Ghosh of Calcutta, of the freezing-points of strong solutions, which would seem to have attracted more attention in Germany than in this country. There is also more said about the equation of state of solids and their expansion coefficients.

We have dwelt perhaps with undue weight on the question of fundamentals, because this seems to us a matter which should be put right. But the present work, supplemented by a proper treatment of those fundamentals, certainly constitutes an excellent course in the general theory of thermodynamics.

Dialectic.

Studies in the Hegelian Dialectic. By Dr. John McT. E. McTaggart. Second edition. Pp. xvi + 255. (Cambridge: At the University Press, 1922.) 15s. net.

IT is curious that a book which professed only to be a study of Hegel, and deals with criticisms of the Hegelian method and principle current more than thirty years ago, should be reprinted to-day and present the same freshness and vigour to the reader now as it did then. This is the feeling with which one who read Dr. McTaggart's book on its first appearance now lays it down, having read it again from beginning to end. It contains the best exposition of the dialectic, and the best defence of the dialectic, and the best criticism of it by any living writer. The conclusion Dr. McTaggart reaches would be accepted probably even by the most convinced Hegelians, namely, the conclusion that the logic is of permanent value and the dialectic sound, but that the metaphysic is unsatisfactory and cannot be final. His own view would seem to be that the ultimate reality is a unity of personalities, but that this unity is not itself a personality. Most of this book was originally presented in papers read and discussed at the Aristotelian Society in the early 'nineties and published in *Mind*, for at that time the Society did not publish Proceedings. It is a living work to-day because, more than at any previous time, the problem of the methodology of science is in the forefront. Mathematical discoveries, which have caused a revolution in our mode of conceiving the physical universe, and the discoveries of the new psychology, which have profoundly changed our mode of conceiving the mind, have necessitated a reconsideration of what is implied in the experimental method. We have found a need for dialectic, for the logic of philosophy. The stone which was set at nought by the scientific builders of the nineteenth century is become the head of the corner.

In the thirty years which have elapsed since Dr. McTaggart's book was written there have been some notable attempts in philosophy to reform and advance the Hegelian dialectic. It would be interesting to know Dr. McTaggart's attitude towards them. In section 120 he seems almost to anticipate Croce's criticism of Hegel as failing to differentiate between "opposites" and "distincts." Also one would like to know how far he considers that Gentile, in the theory he has worked out of the identity of philosophy with its history, has met his objection to the place assigned by Hegel to philosophy in the supreme triad of absolute mind. Dr. McTaggart's own recent work, "The Nature of Existence," gives the impression that he has himself moved away from the position of these early studies and has fallen under the spell of the opposite method to that of the dialectic, the method which is known as logistic and has its home in his college. It may be, however, that he is illustrating in his own mental development the dialectical advance through negation. In any case we can say that this republication of his early work is of the greatest value to those who are endeavouring to follow the constructive work in which he is now engaged.

H. WILDON CARR.

The Methods of Ecological Investigation.

Geobotanische Untersuchungsmethoden. Von Prof. Dr. Eduard Rubel. Pp. xii + 290. (Berlin: Gebruder Borntraeger, 1922.) 16s. 8*d*.

IT is now seventeen years since the first appearance of Prof. Clement's work on "Research Methods in Ecology," written at a time when this branch of knowledge was still in its infancy and its methods for the most part yet to be devised. Since 1905, however, considerable advances have been made, particularly in the two directions of intensive study of the habitat factors and the extensive study of the plant community.

The growth of the subject is indicated by the establishment, both in this country and in America, of specialised journals devoted to this field alone, and this growth has naturally been accompanied by the development of a definite technique for the study of plant societies. We therefore welcome the work before us, in which Prof. Rubel has aimed at giving us a survey of the present position of ecological methodology on the botanical side.

Broadly the subject matter falls into two sections corresponding to the two main lines of progress already mentioned. Of these the consideration of the factors of the habitat, climatic, edaphic, biotic and orographic, with the methods of their measurement, occupies nearly half the text.

The climatic section contains a useful account of several American types of atmometer, methods of measuring light intensity under water, etc. The section treating of edaphic factors is regrettably short, especially having regard to the extensive development in this direction. For example, details might usefully have been furnished of the freezing-point depression methods of estimating the concentration of soil solutions

and the more fundamental methods of chemical analysis. No description is given of a modern type of calcimeter such as that of Collin's, but only of the two Passon's calcimeters in which the sources of error still remain. Again, ecologists might reasonably hope to find in these pages an account of either the electrical or colorimetric methods for determining the hydrogen-ion concentration of soil solutions, or of the colorimetric determination of nitrates.

It is particularly in respect to physical and chemical methods, of which the details are often widely scattered in non-botanical literature, that the biological investigator needs most guidance. The elucidation of ecological problems is becoming every day more a question of the investigation of the chemical and physical properties of the environment as they affect the different species directly, and their relationships to one another.

The second part of the volume is devoted to a consideration of the plant community, and is a helpful summary of the recent work on the extensive side of the subject. Here are dealt with such aspects as frequency and the methods of its determination, the occurrence of "constants" and characteristic species, the life forms of plants as classified by Raunkaier, the chief plant formations and the important subject of cartography.

Prof. Rubel's considerable experience in the Swiss Survey lends especial value to his pertinent discussions of the various statistical methods. The results so obtained are often by no means free from the personal equation, and hence often have a spurious appearance of accuracy to which attention is rightly drawn. The classification of plant formations is, in essentials, that put forward by Brockman and Rubel in 1912, based largely on the physiognomy of the dominant species. The chief change is the creation of a new class termed Saxideserta for stony deserts in which cryptogamic vegetation predominates.

Ecology, from the very complexity of the problems with which it deals, must cull its methods from all branches of science, and if we have criticised omissions it is not without a due appreciation of the magnitude of the author's task and of the encyclopædic knowledge requisite to its ideal performance.

E. J. Salisbury.

Avian Minstrelsy.

Songs of the Birds. By Prof. Walter Garstang. Pp. 101. (London: John Lane, The Bodley Head, Ltd., 1922). 6s. net.

In his "Songs of the Birds" Prof. Garstang has given us an unusual but agreeable mixture of science and verse. His introductory essay on avian song is a contribution to the science of the subject which deserves serious consideration. His attempts to set down on paper representations of the songs of different species are also interesting, although opinions will probably differ as to whether he has greatly succeeded where others have failed. Finally, there are the author's own verses about the songsters, often incorporating his representations of their own music; but these, together with the little sketches from Mr. J. A. Shepherd's humorous pencil, scarcely fall within the scope of a notice in these pages.

Prof. Garstang starts from the assumption that "birds are not automatic musical boxes, but sound-lovers, who cultivate the pursuit of sound combinations as an art, as truly as we have cultivated our arts of a similarly æsthetic character. This art becomes to many of them a real object of life, no less real than the pursuit of food or the maintenance of a family." He also, following Warde Fowler, places bird song on the æsthetic level of the rude music of primitive man. The songs of birds, he tells us, "are in each generation an expression of the whole joy of life at its climax of achievement and well being," and he holds that it is wrong to regard them as essentially love lyrics. These views are a welcome reaction from the too mechanical conceptions that are common, but there is at the same time some danger of their leading towards too anthropomorphic ways of thinking.

Much ingenuity has been expended at various times, and with indifferent success, on the attempt to translate birds' songs into human speech or musical notation. Prof. Garstang obviously approaches this vexed question with a knowledge of music and a sense of poetry, and his endeavours to place the matter on a firmer footing are, at the least, interesting and instructive. As "the bird is a minstrel, not a musician," and as "*timbre* and resonance, rather than musical pitch, constitute the dominating features of a bird's sounds," the author has adopted a syllabic notation. His view is that "the secret of representation lies not in punctilious imitation of every sound (which is unattainable), but in accuracy of phrasing combined with a fair approximation to the succession of dominant vowels and consonants." As we have said, however, opinions are likely to differ as to whether the question is really solved, for the personal factor enters so largely into both the hearing of the songs themselves and the reading of the written symbols. The reader who has an ear may thus best judge for himself whether a useful advance in the means of studying and describing bird music has been achieved by such examples as the following representation of the song of the willow-warbler.

Sip, sip, sip, see! Tee, tew, wee, tew!
Witty, witty, wee-wee, weetew!

Our Bookshelf.

Columns: A Treatise on the Strength and Design of Compression Members. By Dr. E. H. Salmon. (Oxford Technical Publications.) Pp. xvi+279. (London: Henry Frowde and Hodder and Stoughton, 1921.) 31s. 6d. net.

THE question of the strength of columns is one of considerable difficulty, on both the theoretical and the experimental side, and the author is to be congratulated on the value of his contribution to this subject.

Dr. Salmon's book consists of three parts: Part 1 is a bibliography arranged chronologically and gives the author's name and the title of the work. Part 2 is an analytical discussion covering various methods of fixing the ends; in each case ideal conditions are first assumed, and then departures from these conditions are considered until the ordinary column is reached. Part 3, synthetical, contains accounts of various formulæ used in practice and the experimental evidence on which they are based. The last two parts are taken substantially from a thesis submitted for the D.Sc. (Engineering) degree of the University of London. Part 1 in the thesis was historical, consisting of short summaries of each important memoir, including experimental work; it is unfortunate that, owing to the present impossibility of publishing the complete work, this section has been compressed into a bibliography of sixteen pages. The treatment in Part 2 is mathematical without unnecessary refinements.

Apart from the advantage of the presentation in one volume of much valuable work, hitherto scattered in many books and journals, the author's systematic treatment has led him to elucidate various new points, and will undoubtedly stimulate the reader in the same direction. For the same reason the suggestions given for future research must carry weight. Dr. Salmon considers that the most pressing point for future research on columns is the question of the degree of imperfection common in practical direction-fixed ends. This matter is of great importance in other structural members as well as in columns, e.g. arch ribs and encastré beams. We can thoroughly recommend the volume to all who are interested in the subject of the strength of materials.

A Text-Book of Mineralogy: With an extended Treatise on Crystallography and Physical Mineralogy. By Prof. Edward S. Dana. Third edition, revised and enlarged by Prof. William E. Ford. Pp. ix+720. (New York: J. Wiley and Sons, Inc., London: Chapman and Hall, Ltd., 1922.) 25s. net.

THIS well-known book was first published in the year 1877, and a second edition appeared in 1898. The present third edition leaves the form essentially unchanged, the close relation between the author's "System of Mineralogy" and this book having rendered it inadvisable to revise the chemical classification of the minerals until a new edition of that larger work can be undertaken. The distinguished author is now professor emeritus at Yale; he still retains the post of curator of Mineralogy, however, but being well advanced in years the revision of the book has been undertaken by Prof. Ford.

The principal changes appear to be the introduction of a section on stereographic and gnomonic projections, and improvements in the description and explanation of the optical properties of crystals. The reference to the very important recent work on the elucidation of crystal structure by means of X-rays, however, occupies only slightly more than one page, without a single illustration. On the other hand, however, there is a much longer and really valuable section on the determination of the refractive indices of microscopic crystals by the more recent improved microscopic methods of F. Becke and F. E. Wright.

We are glad to see that the references to classes of lower than full systematic symmetry as "hemihedral" and "tetartohedral" (possessing a half or a quarter of the full number of faces) is now only a passing one, as to an antiquated, misconceived, more or less discarded and inadequate method of description. The crystal classes are now referred to as possessing each their own definite elements of symmetry, the only truly scientific method of distinguishing them.

A. E. H. T.

General Economic Geology: A Text-book. By Prof. W. Harvey Emmons. Pp. xiii+516. (New York and London: McGraw-Hill Book Co., Inc., 1922.) 20s.

STUDENTS and others interested in economic geology will appreciate Prof. Emmons's volume. The scope of the work is extremely wide and all of the following are dealt with: coal, petroleum, natural gas, metalliferous and non-metalliferous minerals of economic importance, and building stones.

The text as a whole shows a great resemblance to that of two of the author's previous works, e.g. "Geology of Petroleum" and "Principles of Economic Geology," but the section on coal is entirely new. The chapter on oil appears to be a précis from the former of the two books mentioned, and some parts dealing with mineral deposits have largely the same text and diagrams of the corresponding earlier work. The chapters on the non-metallic minerals, however, have been greatly enlarged, and contain much additional information.

It is evident that the author has written his "General Economic Geology" primarily for an American public, since all his examples, where possible, are from American localities, with little or no mention of occurrences of equal or greater importance in other parts of the world. An outstanding example of this is the 70 pages which he devotes to the coalfields of North America to the exclusion of fields elsewhere.

The value of the book is greatly enhanced by the addition of an excellent bibliography, which will allow of a more specialised study of particular areas when required. Moreover, the text throughout is plentifully supplemented with maps, diagrams, and half-tone blocks.

Imperial Institute Handbooks. The Agricultural and Forest Products of British West Africa. By Gerald C. Dudgeon. Second edition. Pp. xii+176+plates. (London: J. Murray, 1922.) 7s. 6d. net.

SINCE the first edition of this handbook appeared in 1911 many changes have taken place. The development of British West Africa has experienced a serious

set-back through the occurrence of the war, but useful lessons have been learned and many subjects have come forward or called for increased attention. The cultivation of cotton has been shown to be successful and profitable in Nigeria, in the northern provinces great progress has been made in perfecting a cotton originally grown from "American Upland" seed, while the southern provinces have produced increasing quantities of an improved native cotton of the type of "Middling American." The products of the oil palm and especially the kernel of the nut have been in increased demand for edible purposes, but improved methods of extraction are still awaited, and the successful cultivation of the oil palm in the Dutch East Indies and British Malaya threatens to rival the industry in West Africa. Successful plantations of Para rubber have been established in Nigeria and in the Gold Coast, and the latter has become the chief cocoa producer of the world. The extension and improvement of the Agricultural Departments will be a factor in developing the possibilities of the various territories in West Africa for which Great Britain is now responsible. The handbook will serve as a guide to all who seek information on the agricultural and forest products of British West Africa.

Memoirs of the Geological Survey. Special Reports on the Mineral Resources of Great Britain. Vol. 2: Barytes and Witherite. By G. V. Wilson, T. Eastwood, R. W. Pocock, D. A. Wray, and T. Robertson. With contributions by H. G. Dines. Third edition. Pp. iv + 119 + 6 plates. (Southampton: Ordnance Survey Office; London: E. Stanford, Ltd., 1922.) 3s net.

THE issue of a third edition of this memoir shows public appreciation of the economic work of the Geological Survey; the revision has involved further visits to all the principal mines, and the records of output include those of very recent years. A brief sketch of the characters of the two minerals concerned and of their uses precedes the detailed account of the mines. Photographs of crystals, and some account of the relation of barytes to metallic sulphides in the field, might have added interest to this section; but the cost of the memoir to the public has no doubt been carefully considered. The graphic tables showing the total output go back only to 1890. It would be of interest to trace the quick response of the Derbyshire miners to the demand that arose in 1856. The earliest date mentioned on p. 64 is 1892; but in 1857, two years after the industrial development of barytes lodes was started in the county of Cork, Derbyshire produced as much as 9000 tons. The thoroughness of the memoir as a record of present-day mining is shown by the descriptions of methods of treatment of the ore at various places, and of means of transport.

G. A. J. C.

The Edge of the Jungle. By William Beebe. Pp. 237. (London: H. F. and G. Witherby, 1922.) 12s. 6d net.

MR. BEEBE has a graphic pen. His account of the life of bird, beast, and insect as seen from a small clearing on the edge of the British Guiana forest gives a vivid and kaleidoscopic impression of teeming life. His capacity for close and careful observation and his artistic power of selecting just the right details, combine to convey to the reader a feast of tropical colour, sound, and scent. It is impossible not to follow his account of, say, the happenings in the "army ants' home town" with an interest as tense as though he described the fortunes of human individuals. The transformation of "Guinevere" from a tadpole into a tree-frog holds the reader entranced. Mr. Beebe does not confine his attention entirely to his clearing; while on a visit to the gardens at Georgetown he was fortunate enough to see a group of manatees of which he records his impressions for the benefit of his readers. Incidentally he raises an interesting question as to the origin of flower growing for non-utilitarian purposes, which may suggest to the anthropologist a new field in which to view the influence of magic.

Land Drainage. By W. L. Powers and T. A. H. Teeter. Pp. ix + 290. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1922.) 13s. 6d. net.

LAND drainage occupies a large and important place in American agriculture, and the volume under notice is evidence of its prominence. It deals mainly with conditions in the Corn Belt and Western States, and is intended as a practical handbook from which may be obtained the most important details of procedure in the construction of drainage works. As these operations vary according to the nature of the land—reclaiming a marsh presents different problems from the draining of irrigated land which has begun to show signs of alkali—the authors have supplemented their general discussion by detailed descriptions of actual installations. These accounts include the balance-sheets of the operation, which show that in most of the schemes the increased crops have paid for the outlay in a short time. Particular interest attaches to the section dealing with drainage laws, and the manner in which the cost and the benefits of a proposed scheme for a district are divided among the farmers. The concluding chapter is devoted to the care and use of surveying implements, and a useful appendix of laboratory exercises is provided, in which the main principles of drainage are illustrated.

B. A. K.

Homework and Hobby Horses. Edited by H. Caldwell Cook. (Perse Playbooks, No. VI.) Pp. xii + 58. (London: B. T. Batsford, Ltd., n.d.) 3s 6d. net.

THE Perse Playbooks are by now sufficiently well known to educationists. This little volume—the sixth of the series—embodies a selection of poems, ballads, and carols which have been produced, with one exception, by boys of the Perse School as a part of the system of the play-method of teaching English composition. The authors are all under fourteen, and the facility of the verse and, generally, its smoothness suggest that the statement that English verse composition has no terrors for, at any rate, some of the boys, is well founded. Some of the compositions are avowedly parodies, others are obviously derivative, but many show a poetic feeling which is surprising, as well as a considerable command of an appropriate vocabulary. The incongruous, the mark of the unpractised versifier, is commendably absent. It is interesting to note that of the various classes of poems, the carols are by far the most successful.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Cause of Rickets.

THE scientific interest of the work that has been done and is reviewed in the leading article in NATURE of July 29, p. 137, is that it shows that ultra-violet light, acting on the skin, produces by a photo-chemical reaction a definite substance which circulates in the blood. This substance is able to replace vitamin-A in the food; whether wholly or only partially is not yet certain, although it should not be difficult to decide the question. If the former, it appears that light actually causes the formation of the vitamin, as suggested by Prof. Harden, or at all events some compound closely similar to it. Dr. Rollier finds in his sunlight treatment of tuberculosis that cod-liver oil is quite unnecessary; but, of course, his patients get vitamin-A in butter and so on. In rickets, vitamin-A can apparently be reduced to a very small amount if there is plenty of sunlight, but it is uncertain whether the vitamin can completely replace sunlight.

Looking at the evidence as a whole, it seems to me that the six or seven causes enumerated in Dr. Findlay's article may really be reduced to two and perhaps ultimately to one. These two are deficiency of sunlight and of vitamin-A. Taking the remaining suggested causes in the order mentioned, it is obvious that bone cannot be made without its constituents calcium and phosphate, and, as the article points out, this is not a matter of great practical importance, especially if a proper quantity of milk is included in the diet. As to the avoiding of cereals in favour of meat, it seems that the question here is really one of the rate of growth. There is no doubt that the more rapid the growth, the more vitamin-A is needed, probably because it is stored to some extent in the new tissues, especially if these consist of much fat. Prof. Mellanby's experiments showed clearly that the addition of carbohydrate to the diet of his puppies necessitated more vitamin because the growth was so much more rapid than on meat diet alone. It is of interest that Dr. Rollier's experience with tuberculous cases is at variance with Dr. Findlay's with rickets. Rollier finds that much meat is injurious, and that oatmeal is one of the best foods. At the same time, he deprecates over-feeding.

The next cause, rapid growth, has been dealt with above.

I am inclined to think that the factors included in bodily confinement and lack of exercise actually mean lack of sunlight. I understand that at Johns Hopkins Hospital it was found that the two factors mentioned were immaterial if exposure to ultra-violet light was given. It is very doubtful whether massage and electrical treatment have much effect. It is remarkable that the effects ascribed to these are obtained by Rollier in cases which of necessity have to be quiet, such as tuberculous vertebræ, by the action of sunlight alone. The firmness and "tone," even growth, of the muscles is very obvious.

I doubt whether much advance is likely to be made by obscure references to increase of general metabolism as an explanation of the action of ultra-violet light. The dogmatic statement that animal protein is of especial value rests on no good evidence. Apart from vitamin-A, diet does not seem of great importance, and even this vitamin may be reduced to a very small quantity in presence of adequate sunlight.

Should not "vitamin-B" in the seventh line from the bottom of the first column on p. 138 read "vitamin-A"? And also in the sixth line from the top of the second column?

I would conclude that we can reduce the effective factors in the prevention of rickets to vitamin-A and sunlight. It may be found to sunlight alone.

W. M. BAYLISS.

University College, London.

I AM much obliged to Sir William Bayliss for pointing out my inexcusable mistake of writing "B" for "A" vitamin. One of the advantages of solving the rickets question may be that we shall be able to use a more definitive and memorable nomenclature. "Anti-rachitic" factor is at present plainly inadmissible; it would be pleasant to call it "Hopkins' stuff," were it not obvious that the identity of the substances which promote growth and have a preventive influence on rickets is still an open question.

On the general question it seems to me that Sir William Bayliss is too ready to accept as a demonstrated fact that ultra-violet light, acting on the skin, produces by a photo-chemical reaction a substance which is equivalent to or identical with the factor in cod-liver oil which influences growth and rickets. It is a very tempting hypothesis because it brings into line a number of apparently discrepant observations. But it neglects a great mass of clinical experience which relates the occurrence of obvious rickets to the total intake of food and to the influence of exercise and massage. This experience may not be capable of the precise formulation one would like, it may not be of any very high order of observational or experimental accuracy, but it has, I think, none the less to be taken into account. It is known too, though here again the data are not beyond criticism, that light increases the rate of general metabolism in experimental animals.

The alternative hypothesis suggested in the article seems to have the advantage of bringing all the more or less certain and uncertain data which are available into line. What is, of course, needed is a whole series of clinical experiments made with the control and precision of the observations carried out by Dr. Harriette Chick and her colleagues in Vienna. Experiments of this kind are laborious and difficult. Meanwhile the practical sanitarian can get to work with sunlight and cod-liver oil and abolish the disease before any one has found out what part of the spectrum is effective.

THE WRITER OF THE ARTICLE.

The Phenomena and Conditions of Sex-change in the Oyster (*O. edulis*) and Crepidula.

IN NATURE of December 15, 1921 (vol. 108, p. 500), I described an experiment from which a sexually mature male oyster was obtained of a maximum age of 33 weeks, from the River Blackwater. In this experiment a fair number of oysters born in 1921 were obtained on specially prepared shells kept isolated *in the sea* with the view of determining the conditions of sex at a known age at later intervals. With the aid of a Government grant from the Royal Society it has been possible to follow up the experiment this year with the following highly interesting results. The young oysters this year were found mostly to be sexually mature or had recently spawned. In one sample of 32 examined from shells on the south shore, River Blackwater, most of the individuals were males, but one large individual (28 × 31 mm.)

was found on July 3 to be carrying thousands of young oyster embryos. This same individual was taken to Plymouth and kept alive; on July 18 it was again examined and found to be practically ready to spawn as a male.

It is, therefore, clear that even in England, in such suitable circumstances as occurred in 1921, oysters may become mature as females in the first year of growth, and further that a one-year-old oyster which had spawned as a female in the summer following that in which it was born changed immediately after spawning into a male. An examination of about 300 young oysters from the oyster-beds, estimated as one-year-old oysters from comparison with the known one-year-olds, gave the same result as that obtained from the examination of the spat known definitely to have settled in 1921, namely, that all the smaller ones were males but that some of the larger ones were either females or had already spawned as females and were changing or had changed into males. From these results the conclusion is drawn that all oysters are born as males, but may or may not change into females at an age of one year. The proofs for this statement are not yet sufficient to establish it as a fact, and indeed actual proof could only be obtained in the most fortuitous circumstances. The kind of result required to amount to proof would be one which gave 1000 individuals all males out of 1000 individuals examined, but as oyster larvæ settle at different intervals over a period of several months, a heterogeneous population with regard to age—apart from other causes—results unless very special precautions are taken. Since, however, sex-change may occur very rapidly, a difference in age of a few months in young oysters is sufficient to give time for sex-change in a collection of rapidly growing oysters whose greatest age is not more than one year, hence the difficulty. In spite of the difficulties, however, the knowledge of the conditions of sex-change mentioned above will help towards designing an experiment to lead to a definite result.

An extremely interesting result follows the observation that an oyster may function as a female at an age of one year, namely, that Gerbe's work in 1876 (*Revue et Magasin de Zoologie pur et applique*, 3 serie, iv.) can be regarded as confirmed. Gerbe examined 435 one-year-old oysters and found 35 with spawn in the gill, 127 with eggs in the gonad, 189 with sperm in the gonad, and presumably 84 with the gonad undifferentiated. An additional observation supporting these was also obtained from the Blackwater experiment mentioned above. A few Portuguese oysters (*O. angulata*) settled on the shells at the same time as the native oysters. By good fortune one ripe male and one ripe female were obtained. An artificial fertilisation made from these two individuals gave a very good proportion of swimming oyster larvæ and quite as good as a control gave on adult Portuguese oysters.

Thus Gerbe's results—although nearly 50 years old—may be accepted and taken into account definitely in discussions on sex in the European oyster. There is nothing in his results at variance with the observations described above. The view one naturally took of Gerbe's results—prior to the writer's observations given above—was that European oysters at birth developed in approximately equal numbers into males and females, and in view of sex-change afterwards taking place from female [1] to male and almost certainly also from male to female, the sex-phenomena in this species appeared to be unique. The rapidity of sex-change in oysters must now, however, be taken into consideration, and the writer's view of the sex-changes in the young oyster found to be carrying embryos this year may be recapitulated. That oyster settled some time in 1921 after June 9, it is predicated that this oyster became sexually mature as a male and spawned as a male in the summer of 1921 (see NATURE, December 15, 1921). On July 3 this year this same individual had spawned as a female and was carrying thousands of young, and on July 18 this same individual was again sexually mature and practically ready to spawn as a male. Thus this oyster has already had two and probably three experiences of sex alternating from male (?) to female and from female back to male within about one year. It is hoped to follow further sex-changes in this particular oyster, which is still alive, for its last condition of sex, namely as a male, was determined by tapping the gonad through a boring in the shell. It has been found that if the boring and tapping operations be carefully performed an oyster can easily and quickly recover and cement over the boring on the internal face of the shell.

The definite information obtained from this one oyster is corroborated by sex-conditions in other young oysters taken from the grounds whose age could be determined as one-year-old oysters with practical but not with absolute certainty. As indicated above, however, the conditions in 1921, namely the unusually long warm summer, were highly abnormal, and it is not to be expected that one-year-old female oysters will often occur in British waters.

The rapidity of the sex-change in oysters is paralleled by a similar observation on sex-change in the American slipper-limpet (*Crepidula fornicata*) in the same series of experiments in 1921–22. Crepidula, moreover, has undoubtedly a similar span of life to that of the European oyster. Sex-change from male to female occurred in *isolated* slipper-limpets (up to 26.5 mm. long) in the same period as that observed in the oyster, but unfortunately none of the sex-changed limpets were actually in spawn at the time of examination although the gonad in several cases was full of either ripe or fairly large ova, and the penis had been reduced to a mere discoloured trace. Individuals of a similar age settled on other slipper-limpets had the normal beautifully-shaped and well-developed healthy black penis of the young male. (See Orton, Proc. Roy. Soc., vol. 81, B, 1909, p. 469.)

The conditions under which sex-change occurs in the oyster and the slipper-limpet are of much general interest. In the oyster development of both the male and female sex-elements can occur in the winter and spring period. We also know that male-elements can begin and attain full development in the summer and autumn, but as yet we have no definite information about the development of the female sex-elements in the summer and autumn. Experiments have been started to obtain information on the latter problem, but until that information is obtained one is not in a position to discuss the possible causes of sex-change in the oyster. It would appear, however, that the factor for sex-causation is within the control of the organism and not in external conditions, but it will be more profitable to await further information on sex-phenomena before discussing the question fully. In Crepidula there is no doubt that sex-change occurs in young forms when the young males cannot function as males; on the other hand, if young males settle down on females, they undoubtedly remain males and function as such for a variable time, which may be as long as five or six years or as short as one year, but again the underlying factor appears to be that of opportunity to function as a male. The

[1] More than 100 cases of authenticated change from female to male have now been accumulated.

development of the male sexual elements in Crepidula is certainly independent of season, and so also apparently is that of the female sexual elements, since Crepidula breeds almost continuously from about March to December.

The males of Crepidula can certainly recognise females by some particular sense as yet unknown, as will be seen from the following facts. In examining a large number of chains of Crepidula (see Orton, 1909, *loc. cit.*), small to medium Crepidula were often found isolated and settled on the left-hand side of the females. Now this is the wrong side to permit of copulation, but in spite of the fact that copulation could not be effected these individuals were found to have an unusually fat and extensible penis capable of stretching probably twice as far as usual. In the experimental observations described above it was found that isolated Crepidula—certainly not older than those settled in the wrong place—had their penis absorbed. The conclusion is obviously reached that the males on the females knew that the latter were there and tried their best to reach them, whilst the totally isolated ones have resigned themselves unreservedly to a complete sex-change. It is only since proof has been obtained of rapid sex-change following complete isolation that a satisfactory explanation could be given for the phenomena of the misplaced males, but the explanation given above has for a long time been suspected of being the correct one.

Wegener's Displacement Theory.

I QUITE agree with Mr. Lake's remarks (July 15, p. 77) as to the unsuitability of the tracing-paper method of investigating the merits of Wegener's hypothesis. All who wish to pursue the subject will do well to adopt his suggestions as to the practical method.

For some time I have been engaged on the subject, and, though I must plead guilty to the use of the tracing-paper method in the first instance—and there is this to be said in its defence, that we are attacking the master with his own weapon—results certainly warrant Mr. Lake's mild censure that for the truth of Wegener's theory to be accepted we must also believe in a great degree of plasticity for the earth's crust.

If the American coast be superimposed on that of Africa, the parts that coincide (according to Wegener, with a divergence of never more than 100 kilometres) are confined to that represented on the African coast by the distance from Kamerun to a point slightly north of the mouth of the Orange River. There is a divergence along the coast of Cape Colony, and an angle of approximately 15° between the superimposed coast of South America (N.E. coast of Brazil, etc.) and the African coast along the Gold Coast, Ivory Coast, Liberia, etc. These divergences may be easily accounted for by comparatively recent denudation, or fracture.

Assuming the truth of fracture—after Wegener—along the line Kamerun to Orange River, the Zwarte Bergen of Cape Colony certainly do fall into place exactly with the Permian cordillera of the Pampas. But this added coincidence merely leads us into greater difficulty. For to make the superimposed American coast coincide with the African coast in this manner, we have to swing the American continent through an angle of 45° from its present position.

This leaves us with Newfoundland in the position approximately 45 W., 32 N.—in the Atlantic Ocean. The Hercynian Appalachians—another of Wegener's "test" ranges—appear in [illegible] position in the Atlantic north of Cayenne, stretching in a general N.N.E. direction (along the line 52 W., 8 N.—[illegible] W., 20 N.). They are in the right direction for joining up with the British Hercynian range, but are separated therefrom by a distance of ocean above 2000 miles.

To lessen this distance, and bring it within a reasonable distance of the British Hercynian range for joining-up purposes, we cannot allow any bending of the American continent. Any alteration in the relative positions of North and South America throws the direction of the Appalachians out absolutely and entirely. The only way the joining-up can be done for both the Zwarte Bergen-Buenos Ayres range and the Hercynian range on both sides of the Atlantic is either (1) a great movement of the Eurasian continent south-west, or (2) a movement of the African continent south to a distance of about 500 miles from its present position, and at the same time a rotation about an axis somewhere in the neighbourhood of Suez (for example) of not less than 50°.

In other words, since the fracture, either the Eurasian continent has been rotated in a general S.E. direction (clockwise) or the African and Indian masses in a N.E. direction (counter-clockwise), or both these motions have taken place, from a centre somewhere in the Suez-Madeira Islands line.

Are the Himalayas, the Carpathians, the Alpine system, the Atlas Mountains, the result of the clashing together of the African-Indian, European-Asiatic continents by these movements? As Prof. Sollas has reminded me, the first word on Wegener's theory lies with the astronomers and physicists. To them I leave the task of finding a force which has acted in two parallel directions west on the North and South American continents, making their advance west without rotation relative to each other and overcoming the resistance at the expense of the Andes Cordillera and its continuation in North America, and has at the same time driven the Eurasian and Asiatic continents south-east and the African-Indian continent north-east (relative to the Americas) with such determination that the great folding of the Himalayas-Alps line resulted—and waited until Tertiary times to do most of it.

The Elliptic Logarithmic Spiral.

I AM much obliged to Mr. Wright for his correction (NATURE, July 8, p. 40). I had made a search in English and Continental books on curves and concluded that this spiral had been overlooked as a curve. But it appears to have been recognised in connexion with the spherical pendulum. Prof. Lamb in his "Dynamics," p. 288, as I now find, refers to the curve as "a kind of elliptic spiral," and Dr. Besant describes it as "an ellipse gradually shrinking in size."

I take, however, a little unction in having given the curve a name, especially as it seems to be of importance in damped elastic systems with one degree of freedom, and in fact it may be called a characteristic. Thus in the elastic system without friction, the force displacement diagram is a straight line; with fluid friction varying as the velocity, we have the elliptic logarithmic spiral, and with solid friction, a series of parallelograms. The dissipation per cycle, its rate during the cycle, as well as what may be termed the timbre of the motion, are in this view brought out very clearly.

Mating and Parthenogenesis in Saw-flies.

As the result of recent experimental studies in the biology of saw-flies of the family Tenthredinidæ, with particular reference to their parthenogenesis, I have been struck by the dearth of information as to their mating habits. My observations have revealed a novel point which I wish to record; and, in order to discuss its significance, I present first a brief summary of certain points relative to saw-fly breeding.

1. Females of *Athalia lineolata* Lep., on collecting, were found to be greatly outnumbered by the males; they paired frequently and probably were polyandrous. (The writer has a paper on this in the press.)

2. In certain species, *e.g. Pristiphora pallipes* Lep., the male is excessively rare.

3. In certain species, *e.g. Allantus* (*Emphytus*) *pallipes* Spin., no male has been taken or bred.

4. Some 30 species produce males only by parthenogenesis; some 13, females only by parthenogenesis; about 6 produce both sexes similarly. (See lists of Cameron and Enslin.)

5. A large number of species other than the above are facultatively parthenogenetic, and future work will greatly extend the list. (See work of Miss Chawner and the writer.)

6. Certain species, in captivity at any rate, refuse to pair. (See work of Fletcher, Miss Chawner, and the writer.)

7. Females of *Platycampus luridiventris* Fall., after persistently ignoring the males, may lay eggs parthenogenetically while kept with their food plant under a glass vessel and in the presence of the males. (Writer's observation.)

8. Virgin females of *Phymatocera aterrima* Kl., after laying eggs (which gave healthy larvæ) paired with males presented to them. Unfortunately the females were about spent before pairing and did not lay again.

9. A virgin female of *Nematinus luteus* Panz., after laying eggs which gave healthy larvæ, paired with a male and then, subsequently, laid other eggs. Unfortunately, through the wilting of the alder twigs, which I was compelled to use instead of young trees, I have been unable to rear the presumably fertilised eggs which were laid after the asexual batch. I cannot state, therefore, whether this female's parthenogenetic offspring are different in regard to sex ratio or in germinal constitution from the offspring of the batch produced after fertilisation. This I am hoping to elucidate later in this season by the use of other species.

Points 1-4 are fairly well known, but Nos. 5 and 6 are probably known only to the few workers who have studied the group, while Nos. 7, 8, and 9 result from my studies, and being new, so far as I am aware, they form the *raison d'etre* of this note.

These facts warrant the suggestion that in saw-flies the total sexual or partial sexual indifference of the sexes is a method for regulating (*a*) the numerical balance of the sexes and, *ipso facto*, (*b*) the amount of amphimixis necessary for the preservation of the species.

Again, the female saw-fly, by refusing or accepting fertilisation, or by first refusing the male, then laying asexually, next accepting fertilisation and, lastly, laying presumably fertilised eggs, achieves the same ends as the queen bee, which after fertilisation, produces females and workers from fertilised eggs, and males (drones) from unfertilised eggs. (This assumption, of course, rests upon the fact that the chromosome complement of the females and workers is twice that of the drones.)

The survival value of the parthenogenetic production of females and of both sexes in certain species is not difficult to apprehend, but the production of males only has presented a seemingly freakish and puzzling problem. The solution has been obscured by its being a laboratory observation, isolated, and uncorrelated with a knowledge of what occurs in nature or with such a fact as I have just presented. Doubtless males only may be produced in nature by certain females, but my observation suggests two further possibilities—that (1), in nature, certain females of a species may lay male-producing eggs and, subsequently, after fertilisation, eggs producing both sexes, (2) a certain number of females are set apart as virgins for producing males only, while others pair and produce both sexes. (There is too, of course, the remote possibility that fertilised eggs may yield only females sometimes.)

With such a range of possibilities for the production of the sexes the process of gametogenesis in saw-flies is likely to prove more complicated than has hitherto been supposed and may account for recent anomalous results.

Assistance in prosecuting the work has been rendered through a grant from the British Association.

Some Significant Relations in the Quantum Theory of Spectra.

THE non-radiating orbits of Bohr's atom are given by the relation

$$a_n = \frac{\tau_n^2 h^2}{4\pi^2 mc\mathrm{E}} \qquad (1)$$

The frequency of the wave emitted in jumping from one orbit to another is given by the energy relation

$$h\nu_{n+m\rightarrow n} = \mathrm{A}_{n+m} - \mathrm{A}_n, \qquad (2)$$

or

$$\nu_{n+m\rightarrow n} = \frac{2\pi^2 mc^2\mathrm{E}^2}{h^3}\left(\frac{1}{\tau_n^2} - \frac{1}{\tau_{n+m}^2}\right) \qquad (3)$$

The convergence frequencies, given by the values of m equal to infinity in (3), are given by

$$\nu_n = \frac{2\pi^2 mc^2\mathrm{E}^2}{h^3\tau_n^2} \qquad (4)$$

and correspond to radiation emitted by an electron falling into the orbit a_n from rest at infinite distance. The frequency ν_n involves τ_n for only one orbit, and may be regarded as associated with that orbit.

Between (1) and (4) we have immediately

$$a_n\nu_n = \frac{e\mathrm{E}}{2h} = \text{constant}. \qquad (5)$$

Or, the frequency associated with an orbit is inversely proportional to the radius of the orbit for the same kind of atom.

The average kinetic energy of a particle describing a S.H.M. of amplitude a_n and frequency ν_n (instead of the orbital frequency $n = 4\pi^2 me^2\mathrm{E}^2/\tau^3 h^3$) is

$$m\pi^2 a_n^2 \nu_n^2 = \frac{m\pi^2 e^2\mathrm{E}^2}{h^2} = \text{constant} \qquad (6)$$

for the convergence frequencies of the same atom.

In his theory of chemical reaction and reactivity (Transactions of the Faraday Society, vol. xvii. Part 3, May 1922) Baly assumes (1) that an atom can gain or lose energy in terms of the elementary quantum of energy; (2) that the physical change, attending such gain or loss of energy, occupies a definite period of time which is the same for all atoms; (3) that the elementary quanta of all atoms are integral multiples of a fundamental unit which very probably is the elementary quantum of the hydrogen atom.

Equation (2) means physically that the energy difference $h\nu$ is transferred from the atom to the ether, where it resides as the energy of vibration of a shell of ether, the radius of the shell expanding with the velocity of light. Baly's second assumption gives us the thickness of this shell. If the time occupied in releasing the energy $h\nu = A_{n+m} - A_n$ be k seconds, the number of wave-lengths generated is $k\nu$. The thickness of the shell is therefore

$$k\nu\lambda = kc, \quad . \quad . \quad (7)$$

which is constant and independent of frequency.

Again, as the energy radiated is $h\nu$, and the number of pulses equal to $k\nu$, the energy radiated per period of vibration, or the energy in a shell of ether of the thickness of one wave-length, is equal to

$$\frac{h\nu}{k\nu} = \frac{h}{k} = \text{constant} \quad . \quad . \quad (8)$$

It is interesting to note that Baly's third assumption, viz.

$$h \propto E, \quad . \quad . \quad . \quad . \quad (9)$$

makes the constants of equations (5) and (6) identical for all atoms. For similar identity of the constant of equation (8) it is necessary that, like h,

$$k \propto E \quad . \quad . \quad (10)$$

SATYENDRA RAY.

University College, London, W.C. 1, July 12.

Extraction of Radiolaria from Oozes.

I HAVE recently obtained some deep-sea radiolarian ooze from which I am endeavouring to extract the shells with as little damage to them as possible. I have tried the method advocated by Mr. Martin J. Cole, in which disintegration is brought about by prolonged boiling with a strong solution of sodium carbonate, and also another method in which the deposit is boiled with a saturated solution of sodium acetate, cooled till crystallisation has taken place, and then warmed till the mass has melted and boiled again, repeating this process several times. Although the smaller shells are successfully extracted by this means, I come across many large fragments of beautiful silicious formation, evidently the result of the breaking up of larger and more delicate ones.

I wonder if any readers of NATURE could tell me of a better method of extraction, whereby I may obtain these larger ones entire? If so, I shall be extremely grateful. Evidently the above methods of extraction are too drastic for these more delicate forms.

H. L. THOMAS.

Dyffryn Vicarage, Neath, S. Wales, July 10, 1922.

MR. THOMAS does not state whether his radiolarian oozes are recent or fossil. The two methods which he has employed are primarily intended for the disintegration of fossil earths such as the Barbados material, and as they depend for their efficiency on the disruptive action of crystallisation and the solvent action of alkalis on silica, they are necessarily more drastic in their action than is necessary for the cleaning of recent deposits.

Recent radiolarian deposits differ greatly in their nature, according to the rate of deposition and the depth. In some cases where the ooze has been rapidly formed it requires no further treatment than washing under a gentle stream of water on sieves of various grades. This method has the additional advantage of preserving the calcareous organisms, which are retained on the coarser sieves with the larger Radiolaria. The smaller forms pass through all sieves with the diatoms, etc., and may be separated from the muddy water by elutriation and decanting. If it is not desired to retain the calcareous forms the material may be treated with nitric acid. The general treatment may be found in Cross and Cole's "Modern Microscopy," pp. 257-261 (Baillière, Tindall and Cox, 1922).

Some recent radiolarian oozes have come under my notice in which the rate of deposition has been so slow that the material is already in a subfossil condition, laminated in structure, and with the organisms more or less infiltrated with manganese. Such oozes are refractory; they contain scarcely any calcareous matter and so are resistant to acid treatment. They can be broken down only by repeated treatment with hot soda solution alternated with drying, and such methods are necessarily destructive to delicate organic structures like the larger forms of Radiolaria.

ARTHUR EARLAND.

An Attempt to Influence the Rate of Radioactive Disintegration by Use of Penetrating Radiation.

INVESTIGATIONS carried out by *Ellis* (Proc. Roy. Soc. 101, 1, 1922) at the Cavendish laboratory lead to the conclusion that quantum dynamics probably apply to the nucleus of the atom and lend support to the assumption that the emission of γ-rays from the nucleus precedes the disintegration process. This highly interesting hypothesis suggested an investigation whether the rate of radioactive disintegration can be influenced by exposing the substance to the action of penetrating radiation. Could the nucleus be induced to take up a γ-ray impulse supplied by an exterior source, it would mean a change in its stability and so most probably in the rate of its disintegration. As γ-ray source about 800 mg. radium element were used, and experiments carried out with uranium in radioactive equilibrium with UX and with radium D in equilibrium with radium E.

(*a*) *Experiments with Uranium.*—The thin-walled glass tube containing the radium preparation was placed for six weeks on a 2 mm. thick layer of uranium oxide of 1 cm.^{2} surface; by this arrangement practically all kinds of γ-rays emitted by the radium and all β-rays except the very soft ones reached the uranium preparation. By measuring the β-radiation of the uranium X in equilibrium with uranium before and after the experiment no change amounting to more than 0·1 per cent. in the activity could be detected.

Now, from the uranium quantity used, about 15,000 atoms break down in one second, so we can conclude from this negative result that the natural disintegration of our uranium preparation was certainly not followed by an artificial disintegration of more than 15 atoms per second. The radium preparation employed emits about 10^{11} γ-ray quanta in the time unit, about 0·1 of which was absorbed by the uranium atoms, so it follows that the absorption of $15/10^{10}$ of the emitted γ-impulses by the nuclei of the uranium atoms would have already been sufficient to produce a detectable change in the rate of the disintegration of the uranium.

(*b*) *Experiments with Radium D.*—1·2 g. radiolead chloride from Joachimsthal of 1 cm.^{2} surface was treated in the same way as the uranium oxide for 51 days. The β-activity due to RaE in equilibrium with RaD measured before and after the experiment showed no difference amounting to more than 0·2 per cent. Preliminary experiments with X-rays have similarly given a negative result.

G. HEVESY.

University, Copenhagen, July 11, 1922.

Black Coral.

By Prof. SYDNEY J. HICKSON, F.R.S., The University, Manchester.

IN a short article by Prof. J. Stanley Gardiner published in NATURE of December 15, 1921 (vol. 108, p. 505), attention was directed to the use of black coral by the natives of Java for making bracelets which are believed to act as a cure for rheumatism and to the widespread belief, "from Suez to the most distant parts of the Pacific," in the efficacy of certain magical powers of this substance. The use of black coral for this purpose is not only very widespread at the present day but has been prevalent also among both barbaric and civilised races from time immemorial. The ἀντιπαθές of the ancient Greeks was in all probability a kind of black coral, and was used as an antidote to the stings of scorpions and for other medical and magical purposes. According to some of the older writers the herb given by Mercury to Ulysses as a charm to protect him from Circe was a piece of Antipathes. Rumphius quotes Salmasius as having written in his notes on Solinus that Antipathes was used as a protection against sorcery. Pliny refers to it in his alphabetical list of stones. He says, Book XXXVII., Chapter 54, "Antipathes is black and not transparent: the mode of testing for it is by boiling it in milk, to which, if genuine, it imparts an odour (?) like that of myrrh." Dioscorides regarded Antipathes as a kind of black coral which was possessed of certain medical properties.

These and other references to the substance by ancient Greek and Roman authors do not, it is true, give us any certain clue as to the identity of their Antipathes, and it is only by indirect circumstantial evidence that the conclusion is arrived at that it was the axis of one of two or three kinds of marine flexible coral.

The definition of the word "corallium" as used in the time of Pliny may be derived from the comment he makes upon Gorgonia. "Gorgonia nihil aliud est quam curalium · nominis causa, quod in duritiam lapidis mutatur emollitum in mari; hanc fascinationibus resistere adfirmant."

There is no truth in the belief that corals are soft in the sea and become hard when exposed to the air, and we cannot, in modern times, accept the statement that they have the power of resisting fascinations; but it is reasonable to interpret this definition by Pliny to mean that to the Romans of his time coral was a marine substance with a soft cortex when fresh and that it was commonly believed to possess certain magical properties.

Pliny's milk test for Antipathes is interesting but unfortunately very obscure. The phrase he uses is "experimentum eius, ut coquatur in lacte: facit enim id murrae simile." But similar to myrrh in what respect? In odour, in colour, or in form? Solinus considers it to have been similar to myrrh in odour (Collect. v. 26), but other authors have interpreted Pliny to mean similar to myrrh in colour. I have recently applied this test to a piece of Antipathes in my possession and have found after prolonged boiling in milk there is a faint odour resembling that of heated myrrh, but the colour of neither the milk nor the coral seems to be in any way affected. For this reason I am inclined to believe, until my experiments on this subject are extended, that Pliny meant to say "similar in odour to myrrh."

Let us turn now to another fragmentary indication of the ancient use of black coral. The word "coral" is to be found in two texts of the English version of the Bible (Job xxviii. 18 and Ezekiel xxvii. 16). Prof. Peake has kindly informed me that Gesenius and other commentators consider that the Hebrew word "Ramoth" which is translated "coral" in the E.V. means "black coral," and that the word "Peninim" which is translated "rubies" in the E.V. really means "red coral." Thus Job xxviii. verse 18 should read: "No mention should be made of black coral or of pearls: for the price of wisdom is above red coral." I am not competent to form any definite opinion on the views of these commentators; but if they are right and black coral was known to the ancient Jews there may also be some explanation of a remarkable passage in the writings of Josephus.

In his book on the Antiquities of the Jews (i. 3. 6) Josephus relates that according to Berosus, the Chaldean, there is still some part of Noah's Ark in Armenia, and the natives carry off pieces of the bitumen (pitch?) from it to make into amulets for averting mischief. We have in this passage reference to a substance like bitumen (*i.e.* black and flexible when heated) which was made into bracelets and believed to possess magical properties. Of course, it may not have been black coral at all, but if black coral accompanied by the beliefs in its efficacy against evils of many kinds was transported to distant parts of the world, as we know red coral was transported at that period, it would not be remarkable if it became associated with the Noah's Ark myth. It would be a matter of great interest if scholars learned in Jewish antiquities could throw some further light on the use of either black or red coral by the children of Israel in early times

The making of amulets from the pitch of Noah's Ark, and their use for averting mischief, brings us back to the statement in the article in NATURE mentioned above that the natives of Java make bracelets of black coral for curing rheumatism. The most complete account of this superstition in the Malay Archipelago is to be found in Rumphius's "Amboinsch Kruidboek" (xii. p. 195), published in 1750, in the article on *Corallium nigrum* or *Accarbaar itam.* Rumphius says that the natives make bracelets of it by soaking it in cocoa-nut oil and bending it into the form required over a slow fire while smearing it all the time with oil. It is then polished with a rough leaf. Sometimes it is inlaid with gold or silver ornaments. It is supposed to confer on the wearer all kinds of blessings (*zegeningen*) and to protect him from sorcery. It is sometimes made into sceptres for the chiefs and is also made into a powder by grinding with a stone, mixed with water and drunk as a medicine.

It would take too much space to give in detail the various diseases for which black coral was used as a remedy; but there is one point of difference between the account given by Rumphius of the use of the bracelets in his time and the account given by Mr. Pownall in his letter quoted in NATURE. Mr. Pownall says "the natives maintain that it must be used quite plain; and ornamentation of gold or silver renders them quite useless." Rumphius says that they ornament the inside of the bracelets with gold figures because they say, and "not without reason," that the coral must scratch the skin if it is to do any good. We may wonder if Rumphius smiled to himself when he wrote the words "niet zonder reden" in this sentence.

There were other kinds of Accarbaar or bastard corals which were known to the Malays in the time of Rumphius and used by them for medicinal purposes, but the *Accarbaar itam* or *Corallium nigrum* was regarded as the most important and was held in the highest esteem. Among these was the *Accarbaar puti*, which from the figure given by Rumphius was an Alcyonarian belonging to the family Isidæ and probably to the type genus Isis. This is of some special interest as the Mediterranean species of Isis was held in high esteem by the Mediterranean races in classical times, and was currently believed to represent the petrified hair of Isis. But that is another story, and one about which only the most fragmentary indications remain.

The task of identifying the various kinds of black coral mentioned by the ancient and later writers up to the end of the eighteenth century is extremely difficult, as detailed descriptions of the characters upon which the modern classification is based are almost entirely lacking. The substance was evidently black or brown in colour, it was capable of being bent or twisted when subjected to heat, and it was hard enough to be given a polished surface. Moreover, it may be presumed from various references that it was a product of the sea. It might have been, therefore, the Keratin axis of one of the Plexauridæ, of one of the Gorgonidæ or of one of the Antipatharia, or, finally, of *Gerardia savalia*.

The *Accarbaar itam* of Rumphius was probably a Plexaurid. The figure of the stript coral that Rumphius gives is not conclusive but quite consistent with this identification. In the description of the cœnenchym which covers the axis, when it is fresh, he uses the Dutch work Schorse, *i.e.* bark, whereas in the description of another Accarbaar which is almost certainly a Gorgonid he uses the word Korste, *i.e.* crust. In the description of a third Accarbaar which is obviously an Antipatharian he uses the word Slijm, *i.e.* slime. With such an accurate observer as Rumphius was, we may assume that the use of these different words for the cœnenchym signified a real difference in character between them. In the Plexauridæ the cœnenchym is relatively thick, in the Gorgonidæ it is almost invariably much thinner, whereas in the Antipatharia it is usually little more than a soft and delicate film covering the axis. This identification of the *Accarbaar itam* of Rumphius as a Plexaurid is consistent with Prof. Gardiner's identification of the bracelets obtained by Mr. Pownall in Java as the axis of Plexaura.

Rumphius states that the *Accarbaar itam* is not identical with Pliny's Antipathes because it does not give the smell or colour of myrrh on boiling in milk. For other reasons than this, however, we may feel certain that the Antipathes of Pliny and the earlier writers was not a Plexaurid. The evidence seems to point to the conclusion that the black coral commonly used by the ancients was the form mentioned by Imperato (1599) as Savaglia and now known to science as *Gerardia savalia*. (Until quite recently Gerardia was considered to be an Antipatharian, but it has now been definitely placed in the order Zoanthidea.) The reason for believing that it was Gerardia is that this coral grows in the Mediterranean Sea, whilst the Plexauridæ do not, that it attains to great dimensions (a great specimen in the British Museum being two metres in height and spreading fan-wise to a width of over two metres) and the surface of the branches is smooth and devoid of spines. It is possible that in addition to the Gerardia the main stem of some of the species of Antipatharia that are found in the Mediterranean Sea may also have been used. Gansius in his "Historia Coralliorum" (1666) describes a species, *Antipathes hirsutum*, found in the Sardinian seas which is in length greater than the human stature. The axis of such a specimen if polished would be difficult to distinguish from that of Gerardia.

The difficulty of determining the black coral of the ancients, however, is due to the possibility that they may have imported it from the South, in which case Plexaurid or Gorgonid coral may also have come into use. Thus Pliny says in writing on coral, Nat. Hist. xxxii. 11, "Gignitur et in Rubro quidem mari sed nigrius item in Persico—vocatur Jace—laudatissimum (*i.e.* red coral) in gallico sinu circa Stoechades insulas," etc. This passage indicates that the most valuable kind of coral known to the Romans came from the Îles D'Hyères and other places in the Mediterranean Sea, but a black kind was also imported from the Red Sea and the Persian Gulf, in which seas the *Corallium rubrum* is not found.

Black coral was also known to the Moors in early times, and was very probably obtained by the fishermen engaged in the famous red-coral fishery off Marsa-al-Kharaz, the modern Bona or Bône on the coast of Algeria. The Arabic name for black coral was "yasz" or "yusz," a word which seems to have some resemblance to Pliny's "jace."

These few notes on the use of black coral in early times may seem to be very fragmentary and inconclusive, but they may be, perhaps, sufficient to create some interest in and to stimulate further investigation in a chapter of zoological mythology which has not yet been written. It is probable that classical and oriental research will reveal a great many more references to this substance than are recorded in these notes, and it may be expected that the excavations of the antiquaries will bring to our collections some specimens of black coral that were used in ancient times; but I think there is sufficient evidence to prove that the belief in the magical properties of black coral is not only widespread at the present day but also carries with it the sanction of a tradition which has been transmitted from the early days of our Western civilisation.

The Determination of Stellar Distances.

By Dr. William J. S. Lockyer.

IN his presidential address delivered before the Royal Astronomical Society, in connexion with the celebration of that society's centenary (see NATURE, June 24, p. 815), Prof. Eddington referred to six great landmarks of astronomical progress during that century. He pointed out that this was a record of advance which was *continuous*, and not in great waves followed by periods of exhaustion. As he further remarked, the centre of most rapid progress has shifted from time to time and the various branches of astronomy have had their ups and downs. In this second category may perhaps be placed the determinations of the parallaxes or distances of the stars, because quite recently a very great impetus has been given to this branch of astronomy by the introduction of a rapid and effective new method.

So long ago as 1837 the first successful attempt to determine the parallax of a star was accomplished by Bessel, who made his result known in the last month of 1838, showing that 61 Cygni had a parallax of about one-third of a second of arc. Since that date this research has been carried on continuously and we have now catalogues of the parallaxes of a large number of stars. Among the observatories measuring trigonometrical parallaxes to-day, may be mentioned Allegheny, Dearborn, Greenwich, McCormick, Mount Wilson, Oxford (Radcliffe), Swarthmore, and Yerkes, and these institutions secure material which provides about three or four hundred parallaxes a year.

It is interesting to note that in the early days it was thought that the brightest stars were the nearest to us, and therefore attempts were first made to determine their distances. It was soon found, however, that estimates of distance based upon apparent magnitude were wholly futile, for the greater number of the larger parallaxes determined were of stars of the fifth, sixth, and fainter magnitudes.

The work of measuring the parallax of a star may be considered one of the most delicate operations in the whole field of practical astronomy. There are three methods available. The *absolute* method consists in making meridian observations at different times of the year and then studying the resulting places after all known corrections have been made. The *differential* method may be classed under two sub-heads. The first consists in measuring the position of the star to be studied in relation to neighbouring stars at different times of the year. If the neighbouring stars in the field of view of the telescope be close to the star under examination, a wire micrometer is used, but if distant, the heliometer is the more efficient instrument. The second differential method utilises the sensitive plate and consists in photographing a star region at different times and eventually measuring the positions of the star in question in relation to the neighbouring stars.

It was not until the year 1914 that the spectroscope was applied to the determination of stellar distances, and the method now in use is that originated and developed by Prof. W. S. Adams and other astronomers at the Mount Wilson Observatory in California. It is based on the fact that the intrinsic brightness of a star has an appreciable effect on its spectrum. Thus, if two stars have the same type of spectrum but differ greatly in luminosity they will probably differ greatly in size, density, and in depth of their surrounding gaseous atmospheres. If this be so, then their spectra should exhibit variations in the intensity and character of such lines as are peculiarly sensitive to the physical conditions of the gases in which they find their origin, in spite of the general correspondence between the two spectra. If, as Prof. Adams states, "such variations exist and a relationship can be derived between the intensities of these lines and the intrinsic brightness of the stars in which they occur, we have available a means of determining the absolute magnitudes[1] of stars, and hence their distances."

It has been found that certain lines in stellar spectra do give indications of variation with absolute magnitude,

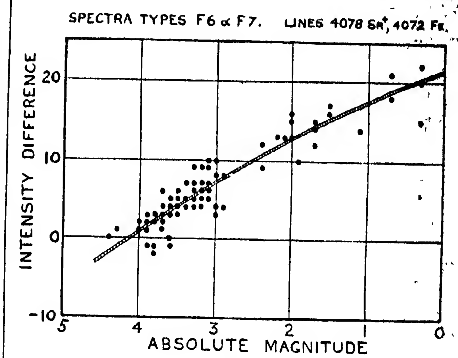

FIG. 1.

One of the fundamental curves formed from *known* parallaxes (black dots of stars of spectrum types F6 and F7

When the intensity-difference in any star of these types has been determined, the absolute magnitude can be read off the curve and the parallax calculated.

and the detection of them we owe to Hertzsprung and Adams and Kohlschutter.

To determine the absolute magnitudes of stars any of three different sources of data can be utilised, namely, the trigonometrical parallaxes, parallactic motions, or proper motions. The most serviceable of these is the first, and reference to this alone will be made here.

The first step in the process is to have available a classification of star spectra based on detailed measurements of line intensities instead of on the more general eye estimations, estimations which have been extremely valuable up to the present time for the general classification of stars but are now superseded. Such a detailed classification for many of the brighter stars has been made and is being rapidly extended.

It is next necessary to construct a series of reduction curves for each type or class of spectrum or for small groups of types (see Fig. 1). These curves are based

[1] The absolute magnitude of a star is its apparent magnitude when reduced to unit distance. (Unit distance = Parallax of 0″·1.)

on the calculation of absolute magnitudes of stars as determined from the apparent magnitudes (which are known) and from the trigonometrical parallaxes (also known) obtained from one or other of the methods previously described. The equation for this computation is as follows:

$$\text{Absolute Mag.} = \text{Apparent Mag.} + 5 + 5 \log (\text{Parallax}).$$

Stars of the same type of spectrum but of different absolute magnitudes are then compared with one another and the relative intensities of selected pairs of lines carefully measured. Curves are then drawn showing as ordinates the observed differences of intensities for each selected pair of lines, and as abscissæ the absolute magnitudes.

With these data it is a simple matter to determine the parallax of any star. Thus, it is only necessary to (1) determine first its type of spectrum, (2) measure the differences of intensities of certain lines in it and refer these values to the curves for that type: the next step is to (3) note from the curve the corresponding absolute magnitude, and lastly (4) determine the parallax from this absolute magnitude by means of the same formula as given above but arranged in a different order, thus:

$$5 \log (\text{parallax}) = \text{Absolute Mag.} - \text{Apparent Mag.} - 5,$$

in which all the members on the right-hand side of the equation are now known quantities.

Thus a single photograph of the spectrum of a star is sufficient for the determination of the star's distance. Naturally greater accuracy is obtained when more than one photograph is examined and several pairs of lines in them are used, but this involves very little extra labour.

The rapidity with which the determinations of parallax can be secured, when once the fundamental curves are formed, is far in excess of that of the older methods. The large powerful instruments of the present day are capable of photographing the spectra of very faint stars, so that a rapid survey of the whole heavens, at any rate to stars of about magnitude 6·5, will be accomplished in the near future.

At the recent meeting of the International Astronomical Union in Rome, great attention was paid to organising this work on an international basis. The Parallax Commission pointed out that there is a large amount of latent information regarding stellar distances in the long series of spectrograms obtained for other purposes at many observatories, and it is to be hoped that these data would be utilised.

A year ago the spectroscopic determinations of parallax were confined entirely to the United States at the Observatories of Mount Wilson and Harvard College. The Astrophysical Observatory at Victoria, B.C., now proposes to examine their slit spectrograms for this purpose.

In this country the only observatory occupied at present with this work is the Norman Lockyer Observatory at Sidmouth. For more than a year the large collection of spectrograms has been undergoing measurements in this connexion, and a large number of new photographs has been taken. An interesting point in this observatory's work is that the measurements of the intensity differences between pairs of lines are being determined by a method originated by the writer, which is different from either of those used at the American observatories. Thus an independent check on the American results is rendered possible.

It is necessary to point out, however, that this research on so large a scale could not have been undertaken had it not been for the opportune assistance rendered by the Department of Scientific and Industrial Research. This Department appointed Mr. W. B. Rimmer, D.I.C., in July 1921 as a research assistant, and his appointment was due to terminate towards the latter end of this year. It is with very great satisfaction that it may now be stated that it has been extended to September of next year. The work is so far advanced that now most of the fundamental curves are completed. It is hoped, therefore, to publish shortly the spectroscopic parallaxes of about 500 stars, followed after a short interval by another 500.

It is satisfactory, therefore, to record that in this new impetus given to the investigation of the distances of the stars, this country is taking a part, and it is hoped that other observatories here which have useful material will join in and discuss it from this point of view.

This line of research should also provide an interesting field of work for the amateur astronomer. The instrumental equipment required need be only on a moderate scale, for a five-inch telescope, fitted with a suitable prism, would meet the case, if a larger one were not available. It is a definite and straightforward piece of research which would be a valuable contribution to astronomy.

Short-wave Directional Wireless Telegraph.[1]

By C. S. FRANKLIN.

DIRECTIONAL wireless telegraphy is by no means a new development for Hertz made use of reflectors at the transmitting as well as the receiving ends in order to augment the effects, and to prove that the electric waves which he had discovered obeyed, to a considerable degree, the ordinary optical laws of reflection. Senatore Marconi, in his earliest endeavours to develop a telegraph system using electric waves, also employed reflectors to increase the range and get directional working.

The discovery by Marconi of the great increase of range obtained by the use of longer waves, and the earthed vertical aerial, practically stopped development on directional lines for the time being. The demand of the time was for increased ranges; and as the first practical application of wireless telegraphy, namely working to and between ships, required "all round" working, there was very little call for directional systems.

To-day the range has arrived at the maximum possible on the earth, and the wave-length has increased to such an extent that the frequencies pro-

[1] From a paper read before the Institution of Electrical Engineers on May 3.

posed are within or near to the limits of audibility. The possible gamut of wave-lengths is becoming very fully occupied, and although the development, during the last four years, of nearly pure continuous-wave transmitters, and of receivers with vastly improved selective powers has eased the problem, the time will soon arrive when the only way of increasing the number of possible services will be by employing systems having good directional characteristics.

There are, broadly, two general classes of directional aerial systems: (a) Those having the general characteristic that their directional power or polar curves are nearly independent of their dimensions. The directional result is obtained by opposing the effects of a number of aerials, or parts of an aerial with suitable phasing adjustments, the degree of opposition being a function of the direction. Systems of this class may be made small compared with the wave-length employed; for the purposes of position finding, and as receiving systems enabling interference to be eliminated from several directions, they have already been developed to a considerable degree. The simplest example of this class is the well-known frame aerial. (b) Those having the general characteristic that their directional power or polar curves depend on their dimensions relative to the wave-length employed. In this class the directional result is obtained by adding the effect of a number of aerials, or parts of an aerial, when working in the required direction. The underlying principle is that the effects, for the required direction, are integrated over a wide front in proportion to the wave-length. Such systems can, therefore, have small dimensions only when using short waves, and this fact makes their development difficult.

As examples of such systems may be mentioned—

(1) Reflector systems in general.
(2) Systems composed of lines of aerials, at right angles to the working direction correctly adjusted as regards phase.
(3) The Beverage long, horizontal receiving aerials.

The reflector system was the first tried for wireless telegraphy. The use of reflectors of reasonable dimensions however, implies very short waves of the order of a few metres, and the very high attenuation of such waves over land or sea, and the difficulty of getting much power into them, tended to make early attempts very discouraging.

The investigation was commenced by Senatore Marconi in Italy in 1916, with the idea of developing the use of very short waves, combined with reflectors, for certain war purposes.

The waves used were 2 metres and 3 metres. The only interference experienced with such waves is from motor boats and motor cars, for these machines apparently emit waves from near 0 up to about 40 metres in length. A coupled-circuit spark transmitter was developed, the primary having an air condenser and spark in compressed air. By this means a moderate amount of energy was obtained, and the small spark-gap in compressed air proved to have very low resistance. The decrement of the waves emitted was judged to be of the order of 0·03. The receiver used was a carefully picked crystal, while the reflectors employed were made of a number of strips or wires tuned to the wave, arranged on a cylindrical parabola with the aerial at the focus. The transmitting system was arranged so that it could be revolved and the effects studied at the receiver.

Reflectors having apertures up to $3\frac{1}{2}$ wave-lengths were tested, and the measured polar curves agreed very well indeed with the theoretical curves. The use of two reflectors with apertures of $3\frac{1}{2}$ wave-lengths, one at the transmitter and one at the receiver, increased the working range about 3 times.

These Italian experiments showed that good directional working could be obtained with reflectors properly proportioned with respect to the wave-length. The attenuation over sea for the wave-length used was found to be very high, and with the apparatus available the maximum range obtained was 6 miles.

The experiments were continued at Carnarvon in 1917. With an improved compressed-air spark transmitter, a 3-metre wave and a reflector having an aperture of 2 wave-lengths, and a height of 1·5 wave-lengths, a range of over 20 miles was obtained to a receiver without a receiving reflector. The experiments at Carnarvon brought into prominence a property of wave propagation which is not generally known, and the extent of which is not realised, namely, the very rapid increase in the strength of the electric field with height above the ground. The rate of increase appears to be a function of the height divided by wave-length, and while not very noticeable with waves of several hundred metres, is very marked with waves of a few metres' length.

It was found that the limiting range at sea level and over sea was 4 miles When both transmitter and receiver are at a low level the range is very dependent on the nature of the intervening country, and is very restricted even over sea; when, however, both stations are many wave-lengths above the intervening country its nature is of far less importance, and the range is increased many times. These experiments showed that very considerable ranges were possible with very short waves.

In 1919 experiments were commenced at Carnarvon with valve transmitters, with the idea of producing a directional telephone system. A wave of 15 metres was selected, which while well within the capacity of the power valves available, allowed a simple reflector to be used without too large a structure. After some trials a single valve transmitter was arrived at taking about 200 watts with a 15-metre wave, and giving 1 ampere in the centre of a half-wave aerial. A heterodyne receiver with supersonic beat-note was employed. Finally, very strong speech was obtained at Holyhead, 20 miles away. The strength was such that shadows produced by small hills and buildings were scarcely noticeable unless the stations were close behind them.

The next point was to test the maximum range, and particularly to find whether such waves would carry over the horizon, and whether there would then be a rapid falling off of strength. Tests were carried out with the Dublin Steam Packet Company's boats running from Kingston to Dublin in June 1920, and speech was received in Kingstown Harbour, 70 nautical miles from Carnarvon, and the point was proved that there

was no rapid diminution of strength after passing the horizon line from Carnarvon.

The range of the system was also tested wholly over land. A site was chosen at Hendon, and a reflector and transmitter for 15-metre waves erected with the reflector pointing towards Birmingham. Tests were commenced in February 1921 from Hendon to a portable receiver on a motor car. Very good speech was received up to 66 miles, and fair speech in the neighbourhood of Birmingham. A reflector station was then erected at Frankley near Birmingham, 97 miles from Hendon, and tests were started there in August 1921.

Measurements with and without the reflectors indicate that the energy received when both reflectors are up is about 200 times the energy received when not using the reflectors. Local measurements of the polar curves taken round the station show that the electric field in front of the station is increased approximately 4 times by the use of the reflector, and that the same order of increase is obtained during reception; the increase of energy received due to the use of the two reflectors should therefore be $4^2 \times 4^2 = 256$ times.

During the continuous-wave tests at Carnarvon it was found that reception was quite possible on the transmitting aerial while the transmitter was operating. The heterodyne may be either the transmitter, or an independent small heterodyne in the receiver. Both the transmission and the reception utilise the same aerial and reflector, and the transmitter is left going and can be operated while receiving.

There is no reduction in strength while the transmitter is on, but a practical trouble has appeared. Owing to the comparatively large power, strong currents are induced in all conducting structures and circuits close to the reflector and transmitter, such as the supporting towers and buildings, and every variable contact produces a noise. The elimination of all variable contacts in the neighbourhood of the transmitter has proved a work of some magnitude.

Reflectors besides giving directional working, and economising power, are showing another unexpected advantage, which is probably common to all sharply directional systems. It has been noted that practically no distortion of speech occurs, such as is sometimes found with non-directional transmitters and receivers.

Although the results between Hendon and Birmingham constitute a record for telephony for ratio of range to wave-length—for such results were believed to be impossible two years ago—they are only a first attempt and do not represent the best that can now be done after the experience gained. But it has been demonstrated that wave-lengths of the order of 20 metres are capable of providing point-to-point directional commercial service over very considerable ranges. Such services will be comparatively secret as compared with the usual non-directional type of transmission.

The directional effect obtained with reflectors which are large compared with the wave-length is so good that it was suggested that it would prove very useful for position finding for ships near dangerous points.

The general idea is that a transmitter and reflector revolving will act as a kind of wireless lighthouse. It is not intended at present for long ranges, but rather that revolving reflectors should be erected in positions similar to those at present occupied by fog signals, and be capable of similar ranges, so as to give the position to ships during fog when within about 10 miles of the danger point.

An experimental revolving reflector was erected on Inchkeith, and tests were made to s.s. *Pharos*, the lighthouse tender of the Northern Lights Commissioners during the autumn of 1920. With a 4-metre wave, spark transmitter, a reflector of 8 metres' aperture, and a single valve receiver on the ship, a working range of 7 nautical miles was obtained. The reflector made a complete revolution once every 2 minutes, and a distinctive signal was sent every half-point of the compass. The bearing of the transmitter could then be determined within ¼ point of the compass, or within 2·8 degrees.

The best method of giving the direction to a ship by means of such a revolving beam requires consideration. When listening in a receiver to a moderately sharp revolving beam the signals are heard only for a very short time. The exact time of maximum signals is not easy to determine by ear, but the times of starting and vanishing are easy to determine, as the rate of rise and fall of the signals is extremely rapid. The time half-way between these two times gives with great exactness the moment when the beam is pointing to the ship.

It would be quite possible to arrange to send a general broadcast signal when the beam passes through true north; then by arranging for the beam to revolve at a perfectly uniform rate, the bearing on the ship could easily be determined by means of a stop-watch. This method is probably the most accurate, but has some disadvantages. It entails accurate timing mechanism at the transmitter, the use of two waves, and three, or perhaps four receivers on the ship, as well as the use of a stop-watch.

For the short wave two receivers are required, one at each end of the bridge, or one fore and one aft. This is necessary to avoid screening by the ship itself. If the broadcast wave for giving the time when the beam passes true north is another short wave, then two more receivers would be required.

The method provisionally adopted avoids accurate timing mechanism at the transmitter and the use of a broadcast wave. On the base of the revolving reflector contact-segments are arranged so that a definite signal is transmitted every half- or quarter-point of the compass.

The apparatus proposed is of a very sturdy nature. The spark transmitters are robust, and last for years without attention. The receivers are simple valve rectifiers with fixed adjustments except for a "backing off" potentiometer for dealing with powerful signals at close range. The attenuation of these waves over sea is so strong that a little experience enables distance to be judged by strength of signals, and this can be measured by means of the potentiometer. The only qualification necessary for a person determining the bearing is the ability to read a few Morse signs.

The success of the present experiments indicates a wide sphere of usefulness for the new short-wave directional wireless system.

Obituary.

PROF. W. WISLICENUS.

BY the death, on May 8, of Wilhelm Wislicenus, professor of chemistry at the University of Tübingen, organic chemistry lost one of its most fruitful research workers, who contributed in no small measure towards placing the science on the basis which it now occupies. He was born at Zurich on January 23, 1861, and was the eldest son of Johannes Wislicenus, that great organic chemist whose name stands on the roll of fame co-equal with those of Hofmann and Frankland. At the time of Wilhelm's birth his father, who had, in the previous year, moved from Halle to Zurich, where he had married Katherine Sattler, the granddaughter of Wilhelm Sattler, joint discoverer of "Schweinfurt green," held the chair of chemistry and mineralogy under the council of the Canton at the School of Industries. Wilhelm may be said, therefore, to have inherited his chemical genius both on his father's and mother's sides.

W. Wislicenus received his early scientific training at the University of Wurzburg, to which his father had moved, in succession to Adolf Strecker, in 1872, and it was from here that he published his first paper, "On a New Reaction between Potassium Cyanide and Phthalide," a reaction which he was able to prove to be of general application, and which he applied to a number of other lactones with fruitful results. In 1885 his father succeeded Kolbe at Leipzig, but Wilhelm continued to work at Wurzburg, and thereafter, until 1903, he published a series of important communications from these laboratories. In this year he removed to Tubingen, where he continued to work until shortly before his death.

The earlier work of Wilhelm Wislicenus is intimately associated with the behaviour of metallic sodium towards organic esters, a problem towards which the attention of many chemists of his time was directed, and in connexion with which his father had already published his epoch-making paper, dealing with ethyl acetoacetate and its application as a synthetic agent, in the "Annalen" of 1877. Indeed, we are told by W. H. Perkin in his Johannes Wislicenus memorial lecture that the laboratory at Wurzburg was, during the early 'eighties of the last century, busily engaged in carrying out syntheses by the aid of ethyl acetoacetate and ethyl malonate. It is not surprising, therefore, that the young Wislicenus should have followed the general trend, and that one of his earliest papers, published from Wurzburg in 1886, should have dealt with the interaction of metallic sodium on a mixture of ethyl acetate and ethyl oxalate, as an outcome of which he was able to discover ethyl oxalylacetic ester. Wislicenus at once realised the importance of this discovery, and he was able later, both by himself and in association with his co-workers, to apply the new reaction to the preparation of a large number of α-ketonic esters, and, indeed, our knowledge of these important substances is mainly due to him.

About this time, also, the general question of the movement of a hydrogen atom from carbon to oxygen, as illustrated by the behaviour of ethyl acetoacetate, and the co-ordination of this phenomenon with others, notably that exhibited by hydrocyanic acid, was receiving considerable attention, and, in 1885, C. Laar published his famous hypothesis in which he coined the word "tautomerism." Laar imagined oscillatory conditions within the molecule which caused the hydrogen atom to take up one or other position alternately. He therefore presupposed the simultaneous existence of both modifications, or, in other words, he considered that the phenomenon was intra-molecular and not inter-molecular. Even at the present time this problem is by no means solved, and it cannot yet be said that Laar was not right in regarding the basis of change as intra-molecular. Still, there is no doubt that, in one of its aspects, the Laar hypothesis did not provide for the existence of the tautomeric individuals, and it was, initially, due to W. Wislicenus that, in this restricted sense, the hypothesis was shown to be wrong. The discovery of the existence of two forms of ethyl formylphenylacetate was made by W Wislicenus in 1887, during his experiments on the action of sodium on mixtures of organic esters. Earlier in the year Piutti had shown that when a mixture of ethyl acetate and ethyl formate was used in this reaction the expected ethyl formylacetate was not produced, or if produced, at once underwent inter-molecular condensation yielding the aromatic compound trimesic ester. In order to avoid this, Wislicenus replaced the ethyl acetate by ethyl phenyl acetate and obtained the open chain formyl esters. He showed that the two esters he isolated were distinct substances, one a liquid giving pronounced enol reactions, the other a solid which possessed the characteristic properties of the keto modification. Since that time many examples of the same kind have been recorded, several of which have been discovered by Wislicenus and his pupils. The whole question is summarised in a lecture given by him at Leipzig in 1897, embodied later (1898) in one of the Ahrens' Sammlungen, in which he clearly enunciates his view that tautomeric phenomena are reversible isomeric changes. Prior to this, in a paper published in the *Berichte* for 1895, the following passage occurred: "Über die Natur der Isomerie ist eine Entscheidung wohl erst nach ausführlicheren Untersuchungen zu treffen, wenn es mir auch am wahrscheinlichsten zu sein scheint, dass hier die bei den Aldehyden, Ketonen, und β-Ketonsaurenestern vermisste tautomeren Formen vorliegen"; a view which was to receive full verification in the later work of Kurt Meyer and Knorr.

Wislicenus continued to work on the general question of tautomeric change for many years after this, and in 1912 he published a further paper in the *Annalen* dealing with the chemistry of ethyl formylphenylacetate. By that time four isomeric modifications had entered the field, but, in the paper quoted, he strongly expresses his view that only two of these, namely, the liquid α-form (enol) and the solid γ-form (M.P. 100°, enol-aldo), are chemical individuals. The β-form (M.P. 70°) and Michael's modification (M.P. 50°) he regards as mixtures of the α- and γ-forms. In 1916, in a paper also published in the *Annalen*, he describes the two forms of the methyl ester of phenyl-

formylacetic acid, both of which are solid, and discusses the curious property of the β-form of combining with methyl alcohol.

It was not, however, in this field only that the experimental skill and keen insight of Wislicenus found scope. His activities in other branches of the science, too numerous to mention in a short monograph such as this, find expression in upwards of one hundred communications, published chiefly in the *Annalen* and in the *Berichte*. Nevertheless, some of these cannot be passed over without comment. For example, in 1892 he discovered a new and simple method for the preparation of hydrazoic acid by causing ammonia and nitrous oxide to react in the presence of sodium. Later, in 1905, in conjunction with Otto Dimroth, he utilised the sodium azide thus formed for the preparation of the simplest organic azide, methylazide (CH_3N_3), by causing it to react with methyl sulphate.

One of the most frequently occurring phenomena met with during the course of organic chemical reactions is that which involves the movement of groups, such as the hydrocarbon radicals, from one element to another, a change which appears to be closely related to that which is associated with the movement of a hydrogen atom within a tautomeric system. Numerous well-known reactions, such as, for example, the Hofmann synthesis of primary amines, the Beckmann rearrangement, and so forth, involve a transference of this kind, and it is, therefore, of interest to note that Wislicenus was able to discover certain typical examples of the migration of an alkyl group from oxygen to nitrogen, and to study the conditions under which the change occurred. Thus, in 1900, he showed, in conjunction with M. Goldschmidt, that phenylformiminoethyl ether, OEt.CH:NPh, is converted, to the extent of about 40 per cent., into the isomeric methylformanilide, when it is heated at 230-240°. Later he was able to prove that the C-methyl ether of caffeine is readily converted into the N-methyl derivative.

Wilhelm Wislicenus was the distinguished son of a distinguished father. His name will always occupy a foremost place in the front rank of the organic chemists of his time.

J. F. T.

Dr. A. G. Mayor

THE death of Alfred Goldsborough Mayor, at the comparatively early age of fifty-four, deprives the scientific world of a worker whose experience in tropical marine biology was unrivalled. Mayor stood in the direct historical succession of American participation in this field, for as the mantle of Louis Agassiz fell on his son Alexander, so did Alexander's mantle fall on the shoulders of Alfred Mayor, who accompanied him as assistant on many of his wanderings in the Pacific. When, in 1904, Mayor was appointed director of the Marine Biological Department of the newly founded Carnegie Institution of Washington, he really entered into his inheritance, and though so many of the projects of his fruitful brain will never mature, the work which has been accomplished at his laboratory in the Tortugas, Florida, and during many expeditions, forms his imperishable monument.

This laboratory, where Mayor died on June 24, is situated at the southernmost point of the United States, 70 miles west of Key West, on a tiny island (Loggerhead Key) which is surrounded by the purest ocean water. It was selected for this especial reason, for Mayor felt that nowhere else in Florida could the proper conditions for the experimental investigation of marine animals be secured. The position is not without disadvantage, and it is generally considered advisable to close down for the autumn hurricane season and for the winter, during which Mayor carried out his expeditions to other seas and islands. The Tortugas Laboratory was generally only available between early May and the end of July. This, however, is the most suitable time for the university research workers of the United States, from whom Mayor drew his investigators by personal invitation. These invitations, to work free of all expense and with payment of travelling expenses, were freely issued to all those whom he felt had some problem which could be favourably attacked at the Tortugas, and until that problem was, as nearly as possible, solved, no pressure embarrassed the research, but season after season it was his custom to reinvite those who had studied with him before and put in their way opportunities which he felt they might have missed before.

The success of his policy is to be seen in the splendid list of researches which stands to the credit of the Tortugas Laboratory. His own publications range widely over systematic zoology ("The Medusæ of the World," published in 1911), comparative physiology (especially the series of studies on the jelly-fish Cassiopea), the physicochemical properties of oceanic water, and biological problems like the growth rate of corals, and reflect his many-sided personality and his abounding energy. The work of his colleagues in whatever subject shows his direct interest and influence and the pains which he took to provide the most complete and satisfactory equipment. Whatever novel line of investigation was likely to throw light on marine work was certain of his most enthusiastic co-operation, and in this connexion may be mentioned the encouragement given to workers on the bacteriology of sea-water, like Harold Drew and Lipman, and the development of scientific under-water photography by W. H. Longley.

The expeditions which Mayor organised and carried out are too numerous to mention, but those to Murray Island, on the Great Barrier Reef, in 1913, and to Tutuila, in American Samoa, in 1915–20, really broke fresh ground in the investigation of tropical marine faunas. At both places he made an intensive study of the coral reefs and was able to demonstrate certain very interesting relations between the physiological characteristics of the different reef corals and their position and development on the reef. These and many other problems of importance were attacked by Mayor and his co-workers, but all the results are not yet published.

Mayor was as faithful in friendship as he was fascinating as a companion. The energy and vitality of his body and mind, his dramatic sense, the tenacity of his memories of men and countries, the range and grasp of his knowledge, all never failed to rouse the admiration of his friends. Something has been said of the zeal with which he furthered the efforts of those who worked with him. It could even be stated that

he endangered the success of his own researches by the readiness of the aid he rendered to others.

Mayor cherished a great ambition to remove the equipment of the Tortugas Laboratory to some locality in the West Indies and make it a truly international meeting-place for biologists. Just before the war his opportunity seemed to have come, and he was about to enter into negotiations for a site in Jamaica when the storm broke It was a bitter disappointment to Mayor that he was not able to proceed with his project after the war, not least because he hoped that, in his yearly assemblies, English biologists would be represented more fully than in the past, and that in this way the cause of Anglo-American unity, which he held very dear, would be furthered. F. A. P.

DR. ALEXANDER GRAHAM BELL.

ON August 1 Dr. Alexander Graham Bell, one of the world's greatest inventors, died at the age of seventy-five years. The effects of early upbringing and environment always leave their mark on a man's life, and in Graham Bell's case they are specially apparent. His father spent the first half of his life as a lecturer on elocution at Edinburgh, and was also a prolific author of books on the same subject. Among his son's earliest experiments were the recording of speech waves on smoked cylinders Graham Bell was a student at Edinburgh University, and later he assisted his father when the latter was a lecturer at University College, London. In 1870, for reasons connected with Graham's health, the family migrated to Brantford, near Tutela Heights, Ontario. In 1873 Graham was appointed professor of physiology at Boston University. In 1874 he invented a system of harmonic multiple telegraphy, and in that year he began a series of experiments which led him at last to realise in practice his conception of an articulating telephone.

Considering the marvellous results achieved the mechanism of the telephone is wonderfully simple Previous to its invention, elaborate devices had been proposed containing large numbers of tuned reeds so as to cover the whole gamut of the human voice. The final form of the instrument is fully described in Graham Bell's patents of 1876 and 1877. Although he made several other notable inventions, the telephone will always be outstanding as his supreme achievement. It first attracted world-wide attention at the Centennial Exhibition in Philadelphia in 1876 After Graham Bell had laid down all the essential principles of telephony, Edison developed his carbon transmitter.

In 1878 the first telephone exchange was established There are now about twenty-one million telephones connected with the various exchanges throughout the world In the early days Graham Bell regarded twenty miles as the limit to which articulate speech could be sent. It has now been sent over five thousand miles.

In 1917 the Bell Memorial Committee presented to Brantford, Ontario, a public park, the house in which Graham Bell lived when he made his epoch-making discovery, and a noble monument, to commemorate the invention of the telephone. Graham Bell in his later years took the keenest interest in aeronautics and geophysics. When Father Cortie recorded the magnetic storm of August 11, 1919, in NATURE (vol. 103, p. 483), Graham Bell wrote to say that he had noticed a display of the Aurora Borealis at Cape Breton Island on that date, "Pulsations of light swept upward to the zenith resembling clouds driven before a heavy wind" (vol. 104, p. 74). He was made a doctor of science at Oxford in 1906, and in 1913 the Royal Society awarded him the Hughes medal and the Institution of Electrical Engineers made him an Honorary Member. On his visit to this country in 1920 the freedom of his native city of Edinburgh was conferred on him. He was held in universal esteem. As the founder of a great and flourishing industry which ameliorates the conditions of life he was a great benefactor to humanity.

A. R.

WORKERS in many branches of science and education will deeply sympathise with Prof. W. A. Bone, professor of chemical technology in the Imperial College of Science and Technology, on the death of his wife on July 26. Before her marriage to Prof Bone in 1916, Mrs. Bone, who was then Miss Liddiard, was headmistress of the St. Albans High School for Girls, and had previously been a member of the teaching staff of the Ladies' College, Cheltenham. She was a graduate in arts of the University of London, and possessed exceptional capacity for teaching as well as for organisation While she was head of the St. Albans High School, the domestic economy school was inaugurated there. Mrs. Bone took an active interest in science progress in general, and her husband's researches in particular, and her death will be regretted by a large circle of pupils and friends who came under her strong and delightful influence.

ORIENTAL learning has suffered a serious loss by the death, at the age of eighty-five years, of Mr. Charles Henry Tawney, C.I.E. Educated at Rugby and Cambridge, where he gained the highest classical honours, and a fellowship at Trinity College, Mr. Tawney joined the Indian Educational Service, and became professor at the Presidency College, Calcutta, where he won the esteem of his pupils by his kindness and learning. He became Director of Public Instruction in Bengal, and retired from the Educational Service in 1892 On reaching England he became librarian at the India Office. Much of his time was occupied in assisting writers on Indian subjects, by whom he was regarded with the greatest esteem. He was an admirable Sanskrit scholar, and published several works, the best known of which are translations of two great collections of Indian folk-tales, the Katha Sarit Sagara and the Katha Kosa, enriched with valuable notes, which displayed a wide knowledge of the literature of folk-tales One of his sons, Mr. R. H. Tawney, Fellow of Balliol, is a distinguished writer and lecturer on economic problems.

WE regret to see the announcement of the death, on July 25, of Dr. Arthur Ransome, F.R.S., lately professor of public health in Owens College and examiner in sanitary science in the Universities of Cambridge and Manchester.

Current Topics and Events.

THERE appears to be solid ground for accepting as an accomplished fact the arrangement which was first rumoured in this country about a year ago. In its annual report, the Compagnie Nationale des Matières Colorantes, the French equivalent of the British Dyestuffs Corporation, declares that "all who understand the complexity of the manufacture of organic colouring matters will realise why we have been compelled to acquire the patents, the processes, and the technical aid of our principal foreign competitors for exclusive use in France." This passage has been taken by the French press as the official description of an agreement between the Compagnie Nationale and the Interessen Gemeinschaft, by which detailed technical assistance and full information regarding processes of manufacture shall be supplied to the French factories by their German rivals, such technical assistance taking the form of German chemists to supervise operation of processes in the French dye-works. In return for these advantages, the consumption of French dyes would be limited to France and her colonies, whilst the profits arising therefrom would be shared by the Interessen Gemeinschaft. Although a superficial view of this plan may not be flattering to national *amour propre*, the arrangement is an eminently practical one. The plain English of it is that a fifty years' start cannot be overtaken in fifty months. The Allies are agreed in declining to trust Germany with a virtual monopoly in dyestuffs manufacture such as she enjoyed before the war, in the first place owing to its military potentialities, and secondly, though not less forcefully, because a flourishing dyestuffs industry offers the most powerful stimulus to encouragement of national talent in the field of organic chemistry—a branch of science which civilised countries cannot afford to neglect. Consequently, it has appeared to the French better to enlist the assistance of Germans in building up a domestic industry than to incur the terrible risks of not having any dyestuffs factories at all. The course which they have chosen may perhaps, in a somewhat modified form, suggest an avenue of escape from British embarrassments in the same industrial domain.

A DEPUTATION from the People's League of Health, which recently waited on the Parliamentary Secretary to the Minister of Labour, in order to direct attention to the effect of unemployment and the unemployment insurance benefit on the health and habits of the nation, referred *inter alia* to the subject of nutrition. Sir Bruce Bruce-Porter said that the amounts paid by way of unemployment benefit were insufficient to keep the worker fit, that the latter was frequently unversed in food values, and would be better able to render good service when trade revived were he able to obtain a standard balanced diet by means of food tickets in part substitution for unemployment benefit. This point is of considerable importance, and although, as urged by the Parliamentary Secretary, there are serious administrative difficulties in the way of any such rationing scheme, we are of opinion that it ought to be considered seriously. The quantitative aspects of the problem of national nutrition need much more attention; we still have very little exact knowledge of the requirements of different classes of manual workers, and the foundations laid during the crisis of the war have not been built upon. We are glad to know that a strong committee, under the chairmanship of Prof. E. P. Cathcart, has been appointed by the Medical Research Council to examine the whole subject, and if possible undertake special research work. The food requirements of soldiers have been ascertained by exact experiment; the work of Cathcart and Orr in this field has been of the greatest value. The application of the experimental method to workers not under military discipline is difficult, while inferences from family budgets are frequently dangerous. However, a combination of the experimental method, applied to a relatively small number of selected individuals, and the statistical method of reducing budgets, will almost certainly lead to a solution of the problem. Similar remarks, of course, apply to the case of institutional dietaries—a subject under the consideration of a committee appointed by the Board of Control. It is doubtful whether the diets approved by various hospital and school committees are really based on any uniform scientific principles.

FROM the Royal Institute of British Architects we have received a notice of the preparations being made to celebrate the bi-centenary of the death of Sir Christopher Wren, who died on February 25, 1723, at the age of ninety-one years. The Royal Academy, the Royal Society, the British Museum, the London County Council, and other important public bodies are represented on the grand committee which has been formed, and the proposal is to have a commemoration week, beginning on Monday, February 26, 1923. The programme includes a memorial service, an exhibition, a pageant, and visits to Wren's buildings. Besides St. Paul's, the choir screen of which bears the oft-quoted inscription, *Si monumentum requiris circumspice*—Wren built about fifty City churches, and to him are also due the library of Trinity College, Cambridge, the Ashmolean Museum, Oxford, and Greenwich Observatory. Had Wren's career not been diverted to architecture, it is probable he would have been among the greatest scientific men of his age, such as Newton, Huygens, and Leibnitz. As a youth at Oxford he displayed remarkable ability, and gained the friendship of Wilkins, Boyle, Seth Ward, and others. In 1657, at the age of twenty-five, he succeeded Rooke as professor of astronomy in Gresham College, London, and three years later returned to Oxford as Savilian professor of astronomy. He was one of the founders of the Royal Society, and was president in 1680-81. Soon after being chosen Savilian professor he was given the sinecure post of assistant surveyor-general under Sir John Denham. The study of architecture,

however, soon engrossed him'; in 1665 he spent much time in Paris, where Bernini was building the Louvre, and the great fire of London gave him an opportunity such as has fallen to few men. Estimating the damage done by the fire at over ten million sterling, Wren drew up an elaborate plan for rebuilding the city with wide thoroughfares and open spaces, and was appointed "surveyor-general and principal architect for rebuilding the whole city"

DR J S FLETT, Director of H M Geological Survey, will act as one of the delegates of the Geological Society of London at the International Geological Congress at Brussels on August 21 to September 3, in place of Prof. W. W Watts, who is unfortunately unable to proceed to Brussels for the congress The other delegates nominated by this society are Prof E J. Garwood, Vice-President, and Dr J W Evans, F.R S.

THE National Research Council of Japan has issued the first number of a new periodical, *The Japanese Journal of Geology and Geography* (Tokyo, 1922), which illustrates once more the wide outlook of science in Japan In this number all the papers are in English, they include one by Prof. Hayasaka recording for the first time the discovery of marine Lower Carboniferous strata in Japan, and one by Dr Niiya, with admirable photographic illustrations, on the mud volcanoes of Minbu, Burma The abstracts of papers published in Japan form an especially valuable feature, since they are given in English or German, almost all in English, and serve to make known a wide range of researches published originally in the national language.

DR MICHAEL GRABHAM has gone to Porto Santo, the northern island of the Madeira group, to study the conditions under which the local race of Portuguese inhabitants are said to enjoy complete immunity from dental caries These people possess huge, ugly, yellow, but sound teeth, and Dr Grabham proposes to bring specimens to London The recent discovery that Porto Santo, which is almost bare of vegetation, has a desirable climate of its own and, moreover, a valuable spring of mineral water, is leading to the incursion of Madeira migrants, and it will be instructive to observe how contact with these new-comers will affect the tooth immunity which Dr Grabham is investigating Valuable knowledge may be thus obtained of a malady which in this country has become a national problem

A PROVISIONAL programme has been issued for the autumn meeting of the Iron and Steel Institute, to be held on September 5-8 at York, under the presidency of Mr. F Samuelson A number of papers have been promised on subjects which, although within the range of the Institute's activities, are of varied character and give promise of an interesting meeting Among the topics which will be dealt with are the changes in properties of steels during heat treatment, modern blast-furnace practice, moulding sands, high-speed steel as well as testing and works machinery. Arrangements have been made for members of the Institute to visit the works of the Staveley Coal and Iron Co. Ltd., near Chesterfield, and of the Parkgate Iron and Steel Co. Ltd., and there will also be excursions to places of interest in the neighbourhood of York. The secretary of the Institute would be glad to hear before August 15 from all who propose to attend the meeting

IT is announced that proposals for closer co-operation amongst the leading engineering institutions, which have recently been under consideration, have now received the approval of the institutions, the representatives of which met in conference, namely, The Institution of Civil Engineers, The Institution of Mechanical Engineers, The Institution of Naval Architects, and The Institution of Electrical Engineers, and that an engineering joint council composed of representatives of these bodies has been formed Among the objects of the joint council will be, to improve the status of engineers, to secure the better utilisation of their services in the country's interests and the appointment of properly qualified individuals to responsible engineering positions, and to prevent the unnecessary duplication of activities. It is anticipated that, at a later stage, the number of bodies represented on the joint council may be increased, but this at present remains a matter for future consideration for the joint council and the institutions concerned

WE have received from the American Bureau of Standards, Washington, Scientific Paper No 437, on the solubility of dextrose in water It is shown from cryoscopic measurements that at temperatures below 90° C three solid phases can exist—ice, α-dextrose monohydrate, and α-dextrose The hydrate is stable between $-5.3°$ C. and 50° C, and has a very high temperature coefficient of solubility. Copies of this paper may be obtained on request to the Bureau of Standards From the same source we have also received Scientific Paper No 435, on metallographic etching reagents for copper alloys, nickel, and the α-alloys of nickel, copies of which may also be obtained on application

THE latest catalogue (No 434) of Mr F. Edwards, 83 High Street, Marylebone, W 1, is devoted to works on voyages, travels, exploration, and adventure in all parts of the world The catalogue contains nearly 1300 titles Many rare volumes are listed, including "The Antarctic Voyage of the *Erebus* and *Terror*," under the command of Capt Sir C J. Ross, 1839–43—The Botany and Zoology of the Voyage, by Sir J. D. Hooker, Sir J. Richardson, J. E Gray, R. B Sharpe, A Gunther, and others, and Gabriel Thomas's "An Historical and Geographical Account of the Province and Country of Pensilvania and of West-New-Jersey in America," 1st edition There is also a set of the "Journal and Proceedings of the Royal Geographical Society of London" from 1830 to 1919

A LIST of the new books and new editions added to Lewis's Medical and Scientific Circulating Library during April, May, and June has just been issued. It is carefully classified and should be very useful for reference. Copies can be obtained free of charge from the publishers, H. K. Lewis and Co., Ltd, 136 Gower Street, W.C.1.

Research Items.

THE ORIGIN OF THE SWASTIKA SYMBOL.—The subject of the origin of the Swastika symbol has given rise to protracted controversy. The latest contribution to the question is that of Harit Krishna Deb in the Journal of the Asiatic Society, Bengal, 1921, No. 3. He suggests that it is a modification of the mode of expressing the ancient Hindu syllable Om, which is used in religious rites. This, a pothook with square ends, was duplicated, one across the other, to form the Swastika, meaning "bringer of blessings," which goes back in India to the seventh century, when it was used as a cattle-mark. Another reference is well before 528 B.C. It is found on gold leaf on a vase with relics of Buddha, and it appears on the Edicts of Asoka (273-232 B.C.). The earliest example known is on a spindle whorl from the third city of Troy, about 1800 B.C., and it is frequent in Greek vases about 600 B.C.

INDIAN PAINTING AND MOHAMMEDAN CULTURE.—The subject of Indian painting has recently attracted increasing attention, and its relation to Culture was discussed by Sir T. W. Arnold in the Sir George Birdwood Memorial Lecture recently delivered before the Royal Society of Arts. He illustrated its relation to Hinduism and Islam in the drawings of Musalman saints and Hindu ascetics, the etiquette of the Mughal Court and of social life, mainly derived from Persia, in the pictures of singers and dancers, of drinking bouts and feasts, and in the short-lived renaissance of Indian painting at the time when the Empire was breaking up. The importance of study of the subject, which would need a series of monographs, was emphasised by Lord Peel, the Secretary of State for India, and by Lord Ronaldshay, late Governor of Bengal.

SPAIN AND IRELAND.—In a lecture recently delivered before the Celtic section of the Société Internationale de Philologie, Sciences, et Beaux-Arts, London, Dr. W. Edmington Scott discussed the prehistoric relations between Spain and Ireland. He pointed out that the history of Iberian names for iron, lead, copper, tin, silver, mercury, gold, and several technical mining and metallurgical terms supplied evidence of long-standing trade communications between Spain and the Minoan and Ægean nations. Their presence in Old Irish pointed to Spanish intercourse with that island. The Phœnician exploitation of the Spanish mines lasted for nearly a thousand years, and it is possible that through these traders and colonists the Andalusian Basque names of the ores were introduced into Assyrian, Aramaic, Hebrew, and other Semitic languages. Tin ore was a necessity for the manufacture of bronze, and this undoubtedly came from the Cassiterides. The analysis of prehistoric Mycenæan, Cretan, and Trojan bronzes proved that they contained a high percentage of tin, whereas Homeric bronze was much weaker. This was due to the scarcity of tin, resulting from the cutting by the Phœnicians of the ancient trade route between Greece and Spain, and the consequent diversion of the mineral resources of the Peninsula to Western Asia.

HEALTH AND WEIGHT TABLES.—Two charts have been prepared by the director of the Galton Laboratory, Prof. Karl Pearson, which should prove of great value to those in charge of infant welfare centres and clinics ("Health and Weight Probabilities," Cambridge University Press, 7s. 6d.). The purpose of the charts is to compare the weight of an individual baby with the average at its age and to give a rough estimate of its chance of surviving the first year of life. Thus, suppose a female baby weighs 10 lbs. at the end of 36 weeks; according to the chart, 97 per cent. of females aged 36 weeks weigh more than 10 lbs. (the chart has been constructed from numerous data of working-class infants), and at the end of the year 74 per cent. of all babies will be healthier than this one. Of course, as Prof. Pearson has pointed out, predictions based upon a single character such as weight are not of a high order of accuracy, but these charts will be very useful. It will be easy to see whether an infant is maintaining or improving its grade of weight and health.

TURBINOID BONES OF *NOTOTHERIUM MITCHELLI*.—H. H. Scott and C. Lord have succeeded in recovering about one-half of the maxillo turbinals of *Nototherium mitchelli* (Studies in Tasmanian Mammals, No. vii., Papers Roy. Soc. Tasmania, 1922). Their general structure is akin to that of the turbinal of a wombat, but their coarseness of texture is about twice that which obtains in the living kangaroos. In being straighter, and more cuneiform in shape, the maxillo turbinals of the Nototherium approach those of the kangaroos and depart from those of the wombats. By reason of their more extensive vertical plates, they approach those of the wombats and depart from those of the kangaroos. By being preceded by a bony platform, the Nototherium turbinals manifest characters of their own, although such states are dimly suggested in the skulls of native bears. The authors conclude that there was a similarity in the lip muscles of Nototherium to those of Rhinoceros.

FLAGELLATES.—Mr. E. Penard gives (Proc. Acad. Nat. Sci. Philad., 1921) the results of studies on several flagellates. He describes in Pteridomonas the "flagellopodia," which may at one moment be flagella and at another form pseudopodia used in the capture of food—a rare condition in flagellates. *Dimorpha tetramastix* is, in the resting condition, a Heliozoon with fine radiate pseudopodia supported by axial filaments, and feeds on a minute ciliate which it captures with its pseudopodia. Arising from an anterior median depressed area are four very fine flagella, and by sudden retraction of the pseudopodia Dimorpha becomes a flagellate within the body of which traces of the axial threads of the former pseudopodia are visible. The organism swims by means of the flagella, but only for a short time, and on coming to rest reverts to the heliozoan form. Another new species of Dimorpha with only one flagellum is described, and this may also assume either the heliozoan or the flagellate form. The author has observed a flagellate stage of Chrysamœba and of Chrysopyxis, in each case the pseudopodia are retracted and a single flagellum is formed.

BIRDS AND SOME INVERTEBRATES OF CEYLON.—The outstanding contribution to the latest part of *Spolia Zeylanica* (vol. 12, part 45) is Mr. W. E. Wait's account of the passerine birds of Ceylon—a preliminary draft of a section for a proposed handbook on the birds of the island. In Ceylon the proportion of passerines in the avifauna is unusually small, for only about 120 species, about one-third of the total bird population, belong to this section, whereas in India fully half the species are passerines. The species are characterised in concise descriptions, followed by short accounts of distribution and habits, and keys are given to the distinctive characters of families and species. Two papers included in the part describe Ceylon Coleoptera—a new species of Luciola, and a collection of Lamellicornia; another continues a description of new species of Ceylon Diptera. Dr. Annandale has contributed a short

account of a polyzoon, *Plumatella longigemmis*, which occurred in the artificial lake whence Colombo obtains its water, and formed a continuous coating on the walls of the wash-water tank at the filtration works. Shorter notes deal with a new species of Lycænid butterfly (*Arhopala ormistoni*), with Lepidoptera of economic interest in Ceylon, and with the stridulation of a leaf-insect.

SURFACE TEMPERATURES IN THE NORTH SEA AND IN GERMAN LAKES.—The International Council for Marine Investigations has just issued a Bulletin Hydrographique (June 1922) containing a summary of all the observations of surface temperature in the North Sea during the years 1905–1914. There are more than 200,000 measurements made from commercial vessels and they are tabulated as means during each ten-day period for the mean year, and for areas of one degree of latitude and longitude, or for one-half degree, in each case. The results are represented graphically by a series of charts, one for each ten-day period. These show in a striking manner the "flow" of the isothermal boundaries throughout the year. A very interesting study of the temperature of the water at the surface of various lakes in Germany has been made by A. Merz (*Veröffentlich. Instituts für Meereskunde*, Berlin, N.F. A., Heft 5, 1920). A specially constructed thermometer was used. The bulb was a vessel of 1 sq. mm. cross-section and 12 cms. long; the capillary stem was 15 cms. in length and was bent at right angles to the elongated bulb. Thus it was possible to explore the water at depths varying by 1 mm. down to about 110 mm. The results are quite remarkable. On very calm days, when there is no vertical disturbance of the water, the temperature may vary from about 21° C. at the surface, to about 8° C. at a depth of about 100 mm. Probably these results will have much significance.

METEOROLOGY AT HONG-KONG.—The report for the year 1921 of the Director, Mr. T. F. Claxton, of the Royal Observatory, Hong-Kong, has just been issued. A heavy rainfall occurred from April 27 to July 6, a period of 71 days, rain falling on 59 days and yielding 59 inches, or 61 per cent. of the total fall for the year. From September 9 to the end of the year, a period of 113 days, the rainfall amounted only to one inch. The total rainfall for the year was 97·34 in. and the average for the past 38 years is 84·62 in. The greatest rainfall in a day was 6·06 in. and the greatest in one hour was 3·25 in. The highest shade temperature was 92° on August 22; the highest in the past 38 years is 97°. The lowest temperature was 44° on February 4, and the lowest for the 38 years is 32°. The maximum wind velocity for one hour was 51 miles; the maximum for one hour in the past 38 years is 108 miles. The maximum squall velocity in 1921 was at the rate of 69 miles an hour. There were 21 typhoons during the year and the tracks of these are given in the Monthly Meteorological Bulletin for December 1921. In addition to meteorological observations kept at about 40 stations in China, meteorological logs were received from 168 ships operating in the Far East, the latter being used for verifying typhoon tracks.

INTERFEROMETERS.—Because of the high degree of accuracy obtainable, interferometric methods of measurement are of extreme value in physical research. The application of such methods has been rendered easily practicable by the various Hilger interferometers, which are specialised developments of the Michelson interferometer. The manufacturers, Messrs. Adam Hilger, Ltd., 75a Camden Road, N.W.1, now include a list of these instruments in their catalogue and have issued separate booklets describing them. The prism interferometer, the lens interferometer No. 1, and the camera lens interferometer (described in NATURE, July 14, 1921) are fairly well known and are used in connexion with various physical problems. A simple and compact form of instrument known as the "interferoscope" is now also available, by means of which the degree of parallelism of surfaces of transparent plates can be determined with more ease and rapidity and with greater accuracy than by micrometer measurement. Minute differences in the thicknesses of opaque parts, *e.g.* steel thickness gauges, plug gauges, balls for bearings, etc., can also be conveniently measured by placing three of the parts between two glass surface plates and measuring the lack of parallelism in the separation of the plates. As the accuracy obtainable with this instrument is about one-millionth of an inch it should form a valuable test-room tool as well as a physical laboratory instrument.

CHEMICAL COMPOSITION OF THE EARTH'S CRUST.—Prof. W. Vernadsky of the Radium Institute, Petrograd, writing from the Paris Muséum d'histoire naturelle, says it has been shown by Oddo and Harkins that the outer shell of the earth's crust, down to a depth of about 10 miles, consists predominantly of elements with even atomic numbers, but he believes that it is now possible to go further than this, and that it can be shown that the elements of different atomic numbers can be grouped according to the part they play in the economy of the earth's crust as follows: 1. *Cyclic (biogenic) elements.* These constitute 99·6 per cent. of the mass of the earth's crust, and 86·4 per cent. of them are elements with even atomic numbers. These elements enter into the composition of organisms, and the chemical changes they undergo are cyclic. They include the following 28 elements: Ag, Al, As, B, Ba, C, Ca, Cl, Cu, Fe, F, H, K, Mg, Mn, N, Na, Ni, O, P, Pb, S, Si, Sn, Sr, Ti, V, and Zn; and probably also the following 10 elements: Bi, Cd, Co, Cr, Hg, Mo, Sb, Se, Te, and W. 2. *Inert gases.*—These have all even atomic numbers. They are chemically inert. They include A, He, Ne, Kr, and Xe. 3. *Elements of the rare earths.*—These include Ce, Dy, Er, Eu, Gd, La, Lu, Nd, Pr, Sa, Tb, Tm, Yb. It is characteristic of these elements that they take no part in the formation of vadose minerals. 4. *Radioactive elements.*—These include Ac, Nt, Po, Ra, Th, and U. They are genetically related to uranium and thorium and are subject to disintegration. 5. *Inert metals.*—These include Au, Ir, Os, Pd, Pt, Rh, and Ru. They do not give vadose minerals. 6. *Diffused elements.*—These include Br, Cs, Ga, In, I, Li, Rb, Sc, and Tl. It is a marked characteristic of these elements that they show very little tendency to form minerals, although their atoms are widely diffused through the rocks of the earth's crust. All the elements of this group have odd atomic numbers. Prof. Vernadsky points out that the chemical processes going on in the earth's crust are closely dependent upon the atomic constitution of the matter of the crust. A portion of this is always in an active state, and is, under present conditions, to be regarded as a store of free energy; *e.g.* those cyclic elements that undergo changes through the influence of radiant solar energy, and those radioactive elements which give a continual display of atomic energy. So long as these sources of energy are maintained, chemical changes will proceed in the earth's crust as at present; but the equilibrium is slowly changing, partly through dissipation and partly through the disintegration of the radioactive elements.

The "Immured Standards" in the House of Commons.

AN interesting ceremony recently took place in the House of Commons, when the copies of the Imperial Yard and Pound which normally rest within the wall of the staircase leading up to the committee rooms, were replaced in their recess, and re-immured by cementing in place the stone slab covering the opening. These "immured standards," officially described as "Parliamentary Copies No. 4," constitute one of the four original sets of copies of the present primary standards of the yard and pound, and were constructed simultaneously with them in 1844–45, with the view of providing a ready means of replacement, should the originals at any time be lost or destroyed. Such a catastrophe occurred in 1834, when the Houses of Parliament were burnt down, the then existing standards being destroyed in the fire. The other sets of Parliamentary Copies were placed, and still remain, in the custody of the Royal Mint, the Royal Society, and the Royal Observatory, Greenwich. At a later date, a fifth set was provided for the Board of Trade, to obviate the necessity for using the primaries in important comparisons, as had been the practice hitherto.

Under statute, these copies must be compared with each other every ten years, and with the primary standards every twenty years, but the immured copies are expressly exempted from this requirement. Hence they have seldom been examined, and were only cursorily re-verified for the first time in 1892, when Mr. H. J. Chaney, the then Superintendent of the Standards, compared them with the Board of Trade copies, by means of apparatus which was taken to the House for the purpose. Since then they have not been disturbed until this year. Upon the present occasion, since this year marks the end of the twenty-year period, it was thought desirable to include the immured copies also in a complete set of inter-comparisons with the other copies and with the Imperial Standards themselves. With the kind consent of the Speaker, and in his presence, the recess was opened, and the standards taken out and inspected, before being removed to the Standards Department for verification. Upon the box there was found the certificate, in original, of their deposit in the present position, after the original site had been demolished during structural alterations. This certificate was dated March 7, 1872, and bore, among others, the signatures of Sir George B. Airy, Astronomer Royal, and Prof. W. H. Miller, both of whom had been closely concerned in the original construction of these standards.

All the comparisons in which the immured copies were involved having been completed, they were returned upon August 3. Mr. J. E. Sears, Deputy-Warden of the Standards, produced them for identification by means of their inscriptions, and after Mr. Percy Ashley, Assistant Secretary to the Board of Trade, had explained the general purpose of the ceremony, the Deputy-Warden announced the result obtained by comparing them against the Imperial Standards. They were then formally replaced in their boxes, which were then hermetically sealed up within a lead sheathing, within an outer oak box, and replaced in the recess, in which they were again immured by cementing the front stone in place. Upon the box there had been placed a record of the proceedings, signed by the principal witnesses, together with the original certificate above referred to, which had been found when the recess was opened.

The results of the comparison of the immured standards with the primaries were given by Mr. Sears as follows:

Yard P.C. No. 4 = Imperial Standard Yard − 0·000101 inch.

Pound P.C. No. 4 = Imperial Standard Pound + 0·00286 grain.

These figures are, however, provisional, since due weight will ultimately have to be given to the results of the other comparisons which are not yet completed, and some adjustment will therefore be necessary. It is interesting to compare these figures with those arrived at in 1844–45, when the standards were first constructed, namely:

Yard P.C. No. 4 = Imperial Standard Yard + 0·000007 inch.

Pound P.C. No. 4 = Imperial Standard Pound − 0·00314 grain.

The apparent variation in the yard is of the order of the differences which have been observed from time to time in the past among the other standard bars, but the apparent change in the pound is more considerable. It may perhaps be explained by the fact that the weight is by no means a good piece of metal, and of all the copies, it constitutes probably the one least fitted to form a trustworthy standard. Some evidence is, however, available, though it cannot be regarded as conclusive, that prior to 1878 the primary standard was rendered a little lighter by wear, arising from its relatively frequent use for important comparisons. The present series of comparisons may render it possible to form some conclusion as to whether this is the case.

The International Research Council.

A MEETING of the International Research Council was held at Brussels on July 25 and the four succeeding days, under the presidency of M. E. Picard, secretary of the Académie des Sciences, Paris; simultaneously the recently formed Union of Scientific Radio-Telegraphy held its first general assembly.

Twenty countries have now joined the International Research Council, the following seventeen being represented at the meeting: Belgium, Canada, Denmark, France, Great Britain, Greece, Holland, Italy, Japan, Norway, Poland, Portugal, Spain, Sweden, Switzerland, United States of America, and Czecho-Slovakia. The representatives of Great Britain for the general proceedings of the Council were Prof. J. R. Ashworth, Sir William Bragg, Sir Charles Close, Sir Richard Glazebrook, Mr. A. R. Hinks, Col. H. G. Lyons, Sir Arthur Schuster, and Dr. E. H. Starling, while in addition Admiral Sir Henry Jackson, Dr. Erskine Murray, and Mr. Shaughnessy represented, together with Sir Richard Glazebrook, the National Council for Radio-Telegraphy.

The greater part of the business of the meeting was concerned with the organisation of international scientific unions additional to the five for Astronomy, Geodesy and Geophysics, Chemistry, Mathematics, and Scientific Radio-Telegraphy, which are already in activity. As a result of the meeting the formation of Unions for Pure and Applied Physics and for Geography seems assured. The proposed Union in

Geology awaits the consideration of the Geological Congress which meets this week at Brussels, and some advance has been made in connexion with the biological sciences.

At a previous meeting of the International Research Council it had been provisionally agreed to unite medical and biological sciences, this decision did not find favour, and the intention now is to separate medicine from Physiology, Zoology, and Botany Proposals will be submitted to the countries belonging to the Research Council, and the ultimate formation of this Union will depend on the number of countries willing to join.

Among other matters dealt with, a proposal submitted by the National Research Council of the United States of America and accepted by the meeting may prove to be an important addition to the responsibilities of the Research Council, which hitherto contented itself with the formation of Unions which became practically autonomous as soon as their statutes were approved. As problems in which several Unions were concerned ran a danger of being neglected, the proposal was now made by the United States that the Research Council itself should take such problems under its own special protection. Three inquiries were mentioned as likely to fall within this category. One of them had already been considered by the International Astronomical Union, which requested the Research Council to make arrangements for a collaboration of several of the Unions in the study of the correlations between solar and terrestrial phenomena The second referred to the energy supply of the world (fuel, solar energy, etc), while a third suggestion dealt with the difficult and complicated question of international patents. The risk of overlapping efforts and the possible fear of interference with the special work of the Unions is avoided by the provision—now coming into force—that the Executive Committee of the Research Council, which hitherto consisted of five members, should be enlarged, each Union nominating an additional member

At the concluding meeting the five members of the Executive Committee appointed by the general assembly were elected as follows: M E Picard (President), Mr. G Lecomte and Prof Vito Volterra (Vice-Presidents), Dr G E Hale, and Sir Arthur Schuster (General Secretary)

The Philosophical Congress at Manchester.

THE special subjects of discussion at the Philosophical Congress recently held at Manchester were (1) the nature of history and its differentiation from science, (2) the concept of unconscious mental process and the justification of the term unconscious in psychology, and (3) the philosophical aspects of the principle of relativity, particularly in regard to the problem of sense perception

The vice-chancellor of the University of Manchester, Sir Henry Miers, presided at the opening meeting, when the Bishop of Manchester, Dr William Temple, gave an inaugural address on "Symbolism as a Basis for Metaphysics" The particular function of philosophy is the interpretation of value Reality presents itself in grades which rise in a hierarchical order from simple matter to life and mind and spirit. Each higher order is the imposition of a value on the lower on which it is dependent and which then becomes for it a symbol Thus a flag as a particoloured strip of calico is mere matter and yet apart from the value which this matter symbolises it has not even the existence which supports the value That is to say, though existence is prior to value, in the higher grade the distinction between existence and value disappears. This led to the further position that the universe can only be explained in terms of will The intellect may be satisfied by a concept of the universe in terms of physical causation, but religious, æsthetic and ethical, and also scientific experience can only be satisfied by proof that it is purposively reasonable and not merely causally intelligible.

(1) "Are History and Science different kinds of Knowledge?" was discussed in a symposium by Mr R G. Collingwood, Prof. A E Taylor, and Dr. F. C S Schiller. The problem is an old one but has acquired new significance in modern thought History is particular and individual, its events are unique, it is impossible to classify them and induce general laws Is it then more than a simple chronicle? On the other hand, science deals with repetitions, its method is experimental, it formulates general laws which enable us to predict and so to control the future.

(2) The subject of the unconscious aroused the liveliest interest on account of its practical importance and the question of the methods of psycho-therapy which it involved. Prof T H Pear presided over the discussion and referred to the great loss which psychology had sustained in the death of Dr W. H. R. Rivers, who had taken part in arranging the programme and had expected to participate in the Congress. The meeting rose in silent tribute The first symposium, "Is the Unconscious a Conception of Value in Psychology?" was by Mr G. C Field, Dr. F. Aveling, and Prof. J Laird In the discussion the medical point of view was represented by Dr. Mitchell and Dr. William Brown The latter gave detailed instances of assumed mental processes which, judged by analogy, are indistinguishable from those of conscious life, the only difference being that the subjects in whom they occur are completely unaware of them. Mr Leonard Russell on the philosophic side defended the use of the apparently self-contradictory term "unconscious consciousness" in a subtle argument directed to show that the paradox is not confined to a particular class of mental phenomena but extends to all, for even in what we call conscious process we are never conscious of the consciousness

A second symposium on the terms used in the new psychology, "The Relations between Sentiments and Complexes," had six contributors The first paper was by the late Dr Rivers, the others were by Dr Bernard Hart, Mr A G Tansley, Prof. T. H Pear, Mr A F Shand and Dr C S Myers. The practical issue in this discussion was as to a possible danger in psycho-analysis Complexes were acknowledged to be harmful and psycho-analysis was directed towards dissolving them, but in doing so might there not be risk of dissolving sentiments which were wholly healthy?

(3) A discussion between Prof G F. Stout and Prof. Alexander on the nature of sense perception was preliminary to a more general discussion on a paper by Prof. A. N Whitehead, "The Philosophical Aspects of the Principle of Relativity." The tendency of the new concept was, Dr. Whitehead said, distinctly to support the line of argument of those who followed Berkeley, and yet it was wrong to suppose that Einstein's principle implied or was even ultimately consistent with the full idealist

doctrine. The new law of gravitation quite as fully as Newton's law referred to a nature common to and independent of all individual minds This was a necessity if there was to be physical science at all in any intelligible meaning of the term. The chairman, Prof Wildon Carr, said that the idealistic interpretation of Einstein's theory did not imply that Einstein was an idealist or that any philosophical purpose was involved in his principle The value of the new principle in philosophy depended on the fact that it was purely scientific and brought forward in the interest of mathematical physics. What it had done for philosophy was to show conclusively that the realist assumption of independent objective existence was not only unnecessary as a condition of the possibility of science but was a positive methodological hindrance

Concurrently with the philosophical discussions the psychologists held a meeting in the psychological laboratory for the reading of papers and demonstrations.

On Saturday the British Psychological Society held separate meetings in the Medical School of the University. In the morning, with Prof T H Pear in the chair, Dr C S Myers described a number of experiments upon the various factors involved in the appreciation of music. He showed how closely the processes of listening to music may follow those involved in the response to pure tones, and considered especially the parts played in the æsthetic enjoyment of music by association, by a process of "distancing," and by "mystical feeling." Mr. F. C. Bartlett gave an account of some experiments leading up to a psychological study of the processes of conventionalisation; and Mr. R. H Thouless discussed the phenomena of contrast in a smoothly graded disc. It was suggested that McDougall's drainage theory could scarcely be accepted as an adequate explanation of the contrast effects, a view that obtained support in the ensuing discussion. In the afternoon the Industrial Section of the Society held a meeting Dr. Leslie Mackenzie presided Mr E. Farmer presented a new method of dealing with curves of output in factory work, and discussed the psychological significance of certain curves representing work in chocolate-packing and glass-blowing Prof. A. V. Hill demonstrated his ergometer, and spoke to a large audience on characteristics of muscular work in the intact organism Mr Jackson read a paper prepared by Mr S Wyatt and himself on the effect of rest pauses upon output curves

The Congress of the Royal Sanitary Institute.

THE thirty-third Annual Congress of the Royal Sanitary Institute at Bournemouth, which was held during the last week in July, displayed the multifarious character of the work embraced in sanitary science or public health Special sections were devoted to sanitary science and preventive medicine, to engineering and architecture, to maternity and child welfare including school hygiene, to personal and domestic hygiene, and there were conferences of veterinary inspectors, health visitors, sanitary inspectors representatives of sanitary authorities, and medical officers of health

Major-General J E B Seely's presidential address was an able summary of urgent public needs, an appeal for clean milk and for judicious expenditure on public health needs including housing, and a reiteration of the fundamental importance of education in advancing public health progress

Sir Arthur Newsholme's presidential address to section 1 dealt with the relative rôles of compulsion and education in public health work He laid down the following general principles as justifying compulsion in public health or social work (1) that the end aimed at by compulsion must be very important for the public welfare, (2) that it cannot be achieved to an equal extent or within a reasonable time by educational measures, not including the education provided by education, (3) that the compulsion can be enforced, and (4) that it is continuously endorsed by a majority of the community He gave examples of the fact that the social history of the 19th century consists largely in a steady extension of the enforcement of compulsory duties and restrictions in various aspects of communal life, each of which had been introduced to secure the larger liberty of the oppressed and handicapped members of the community, and then proceeded to apply these general principles to the case of two chronic communicable diseases like tuberculosis and syphilis, and to alcoholic indulgence His general conclusion was that compulsion in these directions would be effective inversely to the extent to which it was needed, and that in the ultimate issue the two ideals of compulsion and of education of character are not irreconcilable in public health work.

In his address in the maternity and child welfare section, Sir George Newman stressed the continuing but avoidable loss of maternal and infant life, occurring through ignorance and still more through lack of care, and the still larger suffering and disablement of mothers and infants which might have been avoided The fact that 35 per cent of the children first admitted to the elementary day schools in England are so physically impaired as to need medical treatment, emphasises the importance of hygienic and medical care of the mother and of the infant before school age is reached At the present time about *8d* per head is being spent on official services of maternity and child welfare, while the financial value of the lives saved by these services exceeds this sum many times over

There was a useful discussion on "Fuel in relation to health" introduced by Prof J W. Cobb of Leeds University. In his paper Prof Cobb traced the history of the stages through which the manufacture of gas for domestic purposes had passed The New Gas Regulation Act had accepted the fact that the test of intrinsic luminosity was absolute, had permitted the distribution of gas of a lower calorific value than formerly, and had not laid down any limitation of the amount of carbon monoxide in gas Evidently Prof Cobb did not regard increase of carbon monoxide as necessarily increasing danger to the consumer, and he pointed out that although recently more cases of poisoning by this gas had been recorded, they could not be due to increase of its proportion, inasmuch as action in this direction so far had not been great

In a paper on smokeless methods in Glasgow housing schemes Councillor W B Smith emphasised the too little recognised fact that soot from domestic fires is worse than that from boilers of manufacturing plants, on account of the excess of tar products, and advocated central provision of hot-water supplies in towns.

Lieut-Colonel Clemesha described methods of collection and disposal of excreta suitable for small tropical villages, where, as a rule, there is a total absence of all sanitary arrangements. This leads not only to excessive cholera and enteric fever, but to the widespread dissemination of anchylostomiasis,

a parasitic disease, perhaps more destructive of health and efficiency than either cholera or malaria. It was necessary that the provision made for such villages should be primitive in character, and the "pit latrine" was the most satisfactory in most circumstances. Such latrines obviate the need for any conservancy staff and they greatly diminish surface contamination of the ground, and thereby reduce the possibility of spreading hookworm disease. Many of these simple arrangements have been in existence for hundreds of years in countries like Persia, Arabia, and Mesopotamia, and have given rise to no nuisance, but are in all respects satisfactory.

A few only of the subjects discussed at this Congress have been mentioned. The educational value of such meetings stands high. The Congresses of the Royal Sanitary Institute are unique in that they focus the views and wisdom of every profession and calling bearing on public health whether legal or medical, engineering or architectural, women workers voluntary or officials, medical officers of health or sanitary inspectors, veterinary and medical inspectors, representatives of sanitary authorities, and the workers in voluntary organisations. Out of exchange of outlooks from these various angles public health progress is secured.

Pharmaceutical Education and Research.

AT the British Pharmaceutical Conference, held at Nottingham on July 24-27, the President, Prof. H. G. Greenish, delivered an address on "Pharmacognosy and the Pharmaceutical Curriculum." Pharmacognosy, he said, was a field of knowledge that the pharmacist was peculiarly fitted to cultivate, but he would not be able to do so satisfactorily unless he had received a sound preliminary education and had been subsequently trained in chemistry, botany, physics, and elementary zoology. The entrance examination to pharmacy should, he thought, be raised to the level of matriculation, and the training in the sciences upon which pharmacognosy is based should follow and not precede the practical training in the pharmacy which is necessary before the student can present himself for the Qualifying Examination. Dealing with the course of instruction in botany, this, he thought, should be adapted to the object the student had in view, special attention being paid to anatomy, morphology, physiology, and systematic botany.

The training in pharmacognosy should be of a more general and more practical nature than was at present often the case, and should include the determination of diagnostic characters by means of the lens or the microscope or by qualitative chemical tests as might be requisite. In this respect a detailed syllabus was a disadvantage, as it restricted the freedom of thought and the development of a spirit of inquiry which was essential to true progress. In the advanced course of instruction and in the major examination more stress should be laid upon the identification of powdered drugs, the analysis of mixed powders, and the assay of drugs by chemical methods. Opportunity for post-graduate work was very necessary and every possible inducement should be offered to the student to undertake it. The Universities of Manchester and Glasgow had made arrangements for pharmaceutical subjects to form part of the examination for the degree of Bachelor of Science, and if the University of London could be induced to make a similar arrangement a considerable step forward would be made.

The student who had attended advanced courses of instruction in the selected subjects would then be in a position to take the degree of B.Sc. From this he could proceed without difficulty to the degree of doctor of philosophy, the requirement of the University of London being broadly two further academic years of study, including the presentation of a thesis on an approved subject. The work for the thesis could be carried out in an institution such as the research laboratories of the Pharmaceutical Society under teachers recognised by the University. The field of pharmacognosy is so wide, and the problems that await solution are so diversified in their nature, that no difficulty would be encountered in selecting subjects suited to the varied abilities of the students. Great assistance would be rendered in this work by the establishment of an experimental station similar to the Pharmaceutical Experimental Station of the University of Wisconsin at which the material necessary for investigation could be grown and experiments carried out. Possibly such a station could be established in connexion with one of the agricultural colleges.

The determination of the Pharmaceutical Society to foster its scientific work more in the future than it has done in the immediate past was one of the most hopeful signs for the future of pharmacy, and the society, by developing the work which pharmacists were specially trained to do, would go far to establishing its position as a learned society. The president concluded by saying that there might be obstacles to be surmounted, misunderstandings to dispel, and prejudices to be overcome, but the spirit of the pioneers of scientific pharmacy existed to-day and, though latent, was strong. The society should set its educational policy in the direction indicated by the wisdom of its founders and foster the love of the calling which distinguished its early years. So alone would pharmacy ensure for itself the appreciation of a nation.

University and Educational Intelligence.

LONDON.—Dr George Senter, principal and head of the department of chemistry, Birkbeck College, has been selected by the University of London Graduates' Association as candidate for the vacancy in the representation of science graduates on the Senate of the University, caused by the election of Dr Walmsley to the chairmanship of convocation. Dr Senter was formerly a member of the Senate, and has for many years taken an active part in University affairs.

DR WALTER RITCHIE, assistant lecturer in biology in the University College, Aberystwyth, has been appointed assistant lecturer in biology at the Technical College, Bradford, in succession to Mr. L. P. W. Renouf, who resigned his appointment on his election to the professorship of zoology in the University of Cork.

IN accordance with the terms of the will of the late Sir Archibald Dawnay, the Royal Institute of British Architects has awarded, for the first time, two scholarships, each of 50*l.* per annum for two years, to Mr E. U. Channon, Architectural Association, and Mr D. J. A. Ross, Robert Gordon's Technical College, Aberdeen; and one scholarship of 25*l.* per annum, for two years, to Mr C. S. White, Architectural Association. The scholarships are intended to foster the advanced study of construction and the improvement generally of constructional methods and materials and their influence on design.

THE British Research Association for the Woollen and Worsted Industries announce the following awards of research fellowships and advanced scholarships for the year 1922–23: Mr. G. W. Chester, Liverpool, 200*l.* to conduct research on wool fats at the University of Manchester; Mr. John L. Raynes, Nottingham, 100*l.* to conduct research on the bleaching of wool at the University College of Nottingham; Mr. George Barker, Baildon, 100*l.* to conduct research on the action of water on wool as regards strength, elasticity, lustre, dyeing properties, etc., at the University of Leeds. Scholarships have been granted to Mr. Arthur Banks, Sutton Mill, Keighley, tenable at Bradford Technical College, and Mr William B. Elliot, Wellington Road, Hawick, tenable at the South of Scotland Central Technical College, Galashiels.

THE Ministry of Agriculture and Fisheries announces that scholarships in higher agricultural education are offered to the sons and daughters of smallholders and agricultural and other rural workers. The scholarships are of three types: Class I enabling the holder to attend the degree courses in agriculture at certain University departments (including the School of Rural Economy, Oxford, and the School of Agriculture, Cambridge); Class II, tenable for two years at certain University departments of agriculture and agricultural colleges; and Class III, tenable for one year or less, at a farm institute or similar institution. Candidates for Class I and Class II scholarships must be at least 17 years of age, and must show that they have sufficient ability to pass the entrance examination of the Institution at which the scholarship will be tenable; for Class III awards, candidates must be more than 16 years of age and have spent at least a year on a farm or in a horticultural establishment. Applications should reach the Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, London, S.W. 1, not later than August 31.

THE United States National Research Council has made an attempt to ascertain by statistics the relative support given to the arts and the sciences through fellowships and scholarships in the graduate schools of American universities. The result (Reprint and Circular series No. 29, 1922) points to the conclusion that the arts are in this respect more favoured than the sciences. Of 3377 fellowships and scholarships awarded during five years in the graduate schools of arts and sciences of twelve leading universities, 1892 were in arts subjects, 1289 in pure science, and 196 in applied science. The arts subjects were chiefly: English and modern languages (615), history (328), ancient languages (250), philosophy (198), economics (171), political science (153); the pure sciences—biology (400), chemistry (365), physics (152), mathematics (145), geology (104); applied sciences—engineering (105), agriculture (58). The figures do not, however, in any way indicate the extent to which applied sciences are encouraged in the universities, because they do not include the fellowships awarded in the professional schools. A comparison of the number of fellowships awarded with the number of doctorates conferred year by year in the natural sciences discloses in some cases a close parallelism between the two sets of figures; thus in California the numbers of fellowships and doctorates respectively in the five years 1916–17 to 1920–21 were: 23, 23, 16, 16; 15, 16; 21, 14; 25, 22; and in Stanford in 1918–19 to 1920–21: 2, 2; 4, 4; 5, 5. The total number of such fellowships in the natural sciences in the twelve universities during five years was 290, and the number of doctorates 248.

Calendar of Industrial Pioneers.

August 13, 1867. James Shanks died.—Trained at Glasgow University, Shanks abandoned medicine for practical chemistry and in 1836 was employed by Gossage in the erection of his condensing towers. He then became connected with the firm of Joseph Crosfield and Sons, Ltd., at St. Helens; among the notable improvements he made being the introduction of the "Shanks' Vats" used for the lixiviation of black-ash in the production of alkali.

August 14, 1909. William Ford Stanley died.—A native of Buntingford, Hertfordshire, where he was born in 1829, Stanley was trained in mechanics by his father, and in 1854 founded the well-known firm of scientific instrument makers. Besides effecting improvements in the design and manufacture of drawing and surveying instruments, he published standard works on their use and was a versatile writer on various scientific subjects. He was also an enthusiastic promoter of trade schools.

August 15, 1913. James Robson died.—Known for his pioneering work on the gas engine, Robson, who was born in South Shields in 1833, began life as an ironmonger and plumber. Turning his attention in 1855 to the internal combustion engine he built several successful gas engines, and in 1877 took out a patent for a two-stroke engine in which all the pumping and motor actions are performed by one piston in a single cylinder. Robson's first engine on the two-cycle plan was built at North Shields in 1879, and shortly afterwards their manufacture was taken up by Tangye's of Birmingham.

August 16, 1818. Jacques Constantin Périer died.—An able mechanician, Périer founded an engineering works, introduced steam-pumps and hydraulic presses into France, and became a builder of steam-engines. He also invented a centrifugal pump, and drew up a plan for the distribution of the water of the Seine throughout Paris. He published various scientific memoirs, and from 1784 was a member of the Paris Academy of Sciences.

August 17, 1809. Matthew Boulton died.—The founder in 1762 of the Soho Manufactory at Birmingham, Boulton was a successful toy and trinket maker. His friendship with Watt led in 1775 to the famous partnership which made the Soho works known throughout the industrial world. It was there that the modern steam-engine may be said to have had its birth, and much of the success achieved was due to Boulton's energy and business acumen. Boulton himself made many improvements in the art of coining.

August 18, 1874. Sir William Fairbairn died.—A great mechanical engineer, Fairbairn as a journeyman-mechanic gained experience in various parts of the country, and in 1817 set up in business in Manchester. He introduced many improvements in millwork, was a pioneer in iron shipbuilding, with Robert Stephenson built the Britannia Bridge over the Menai Straits, and made original investigations into the strength of materials, the properties of steam, and other subjects.

August 19, 1808. Frederic Henry Chapman died.—Recognised as the foremost naval constructor of his day, Chapman was born at Göteburg in 1721. As a young man he worked in London, and after visiting France became a constructor in the Swedish Service, and towards the end of his career invented the parabolic system of construction. His principal writings were his "Architectura Navalis Mercatoria," published in 1768, and a work on Ships of War published in 1775.

E. C. S.

Societies and Academies.

EDINBURGH.

Royal Meteorological Society, July 24.—Dr. C. Chree, president, in the chair.—C. K. M. **Douglas**: Observations of upper cloud drift as an aid to research and to weather forecasting. The condition of the wind near the top of the troposphere in different stages of a cyclone is discussed. The pressure distributions aloft, disclosed by the upper winds, are considered in relation to temperature, as the pressure at considerable heights is largely determined by the temperature of the column of air underneath. There is complete lack of symmetry in the temperature distribution over a cyclone in its earlier stage, with a great contrast in the temperature of the whole troposphere between the "polar" and "equatorial" currents. When the cyclone becomes stationary and fills up, the distribution of temperature and wind in the upper air approaches to symmetry round the centre, and the easterly current on the north side often extends throughout the troposphere. No simple rules for weather forecasting can be drawn up, as the changes in the wind at considerable heights follow rather than precede those near the surface, but observations of high cloud motion are valuable, for they indicate the temperature distribution in the troposphere.—J. S. **Dines**: Note on the effect of a coast line on precipitation. A convergence effect occurs over a coast line when the wind blows along the coast, the low pressure being over the sea and the high pressure over the land; this may cause precipitation. Under favourable conditions an upward current of 15 feet per minute may be produced over a strip of the earth's surface extending 5 miles on each side of the coast line. A similar effect occurs wherever the pressure gradient varies along a line perpendicular to the isobars, and the following rule is deduced: "In any area where the pressure gradient increases towards the 'High' there will be rising air."—A. E. M. **Geddes** and C. A. **Clarke**: Note on turbulence, as exhibited by anemometer records, smoke and cloud formation. The effect of eddy motion is shown near the surface by the records from a pressure tube anemometer. The turbulence and consequent eddy motion depend largely on the nature of the surface over which the air current is travelling. Eddies higher up are shown by smoke from tall chimneys. Higher up, cloud of the stratus order is formed. Smoke eddies and clouds occur when there is little or no convection due to heated air, and therefore their appearance and formation is evidently in accordance with Taylor's theory of eddy motion. Eddies occur at the junction of two currents of different temperature, and fragments of cloud form below the base of the line squall or similar cloud. Cloud intermediate between the normal cirrus and cirro-cumulus types undergoes changes which are at present unexplained. The change of the cirro-cumulus type, regarded as a water-droplet cloud, into the ice-crystal structure of true cirrus is only to be expected at high altitudes and consequently generally very low temperatures, but the reverse process occurs frequently.

PARIS.

Academy of Sciences, July 10.—M. Emile Bertin in the chair.—Paul **Janet**: The standard reproduction of the international ohm. An account of the preparation of eight standard mercury ohms by the late M. René Benoît. The differences between the values measured by electrical methods and the values deduced from the geometrical dimensions did not amount to more than a few hundred-thousandths. The mean of the absolute values of the deviations was $1 \cdot 9 \times 10^{-5}$.—E. **Cartan**: A fundamental theorem of H. Weyl in the theory of metric space.—A. **Châtelet**: Finite Abelian groups.—J. **Guillaume**: Observations of the sun made at the Observatory of Lyons during the first quarter of 1922. Observations were possible on 74 days during the quarter; the results are summarised in three tables showing number and area of spots, their distribution in latitude and the distribution of the faculæ in latitude.—G. **Sagnac**: The oscillations of the spectral lines of double stars explained by the new law of projection of energy of light.—E. M. **Lémeray**: General relativity and the Milky Way.—R. **Jouast**: Comparisons of the standard reproductions of the international ohms. The standards constructed by the late M. René Benoît were compared by Kelvin's double-bridge method. Of the ten originally constructed one was rejected owing to an accident in mounting, and another had also to be rejected on account of an apparent discontinuity in the tube. Details of the measurements are given. The values range between 0·99984 ohm and 1·00015 ohm.—Vasilesco **Karper**: A particular class of batteries. A voltaic cell is formed by a mixture of amyl alcohol and water containing zinc sulphate in solution. This separates into two phases, the upper being amyl alcohol, the lower an aqueous solution of zinc sulphate. With zinc electrodes this cell gives an E.M.F. of 0·7 volt. The results obtained with this and similar cells are not in accord with Nernst's osmotic theory of cells, and appear to contradict the second law of thermo-dynamics.—P. **Janet**: Remarks on the preceding communication. It is necessary to prove rigorously that the cycle formed by the substances present constitutes a closed cycle.—Albert **Granger**: Observations on the baking of ceramic products in electrically heated furnaces. With platinum-wound furnaces the highest temperature attainable with safety is about 1300° C. For higher temperatures a granulated carbon resistance is necessary. A grey tint on the porcelain made in this furnace was proved to be due to the action of carbon monoxide passing through the wall of the tube (corundum mixed with a refractory clay).—R. **Locquin** and Sung **Wouseng**: Aldehydes obtained starting with tertiary alcohols.—F. **Boiry**: Vulcanising rubber in solution. A study of the interaction of indiarubber in colloidal solution and sulphur with different solvents at high temperatures (over 120° C.). With phenetol as solvent the compound produced contained 31·5 per cent. of sulphur, approximately corresponding to $C_{10}H_{16}S_2$ (32 per cent. sulphur), which may be considered as the ultimate product of vulcanisation.—Hervé de **Pommereau**: The reduction of ethyl α-naphthylacetate and of the α-naphthylethanols by sodium and absolute alcohol.—Emile **André**: Contribution to the study of grape seed oil. Study of the solid fatty acids. Method of separating stearic and palmitic acids.—A. **Duffour**: A new example of hemihedral forms not conforming to the sign of optical activity.—Gabriel **Bertrand** and **Mokragnatz**: The presence of cobalt and nickel in arable soil. The method of extracting these metals from the soil and identifying them is given in detail. A specimen of garden soil (Pasteur Institute) has given 0·0037 grm. cobalt and 0·0174 grm. nickel per kilogram of soil.—I. **Athanasiu**: Nervous motive energy. Electroneurograms.—A. **Desgrez**, H. **Bierry**, and F. **Rathery**: The state of acidosis. Method of proof and treatment.

CAPE TOWN.

Royal Society of South Africa, June 21.—Dr. C. F Juritz in the chair.—**S. H. Haughton**: On some upper Beaufort Therapsida. A new genus of Cynodont reptile, Cynidiognathus, for the species *C. longiceps* based on a skull from the Burghersdorp Beds is described. Its dental formula is i4c1m10. There are well-marked palatine processes of the premaxillae, no prevomers, and the epipterygoid is retracted from the quadrate. A skull thought to be *Cynognathus berryi* is assigned to the new genus under the name of *C. broomi*. The palate and basicranium of Aelurosuchus is discussed; the genus belongs to the Bauriamorpha.—**T. J. Mackie**: Observations on the protective action of normal serum in experimental infection with *Bacillus diphtheriae*. In guinea-pigs experimentally infected with *B. diphtheriae*, normal serum from various animals, injected subcutaneously at the same time as the inoculation, exerts a definite protective action. No protection occurs if the serum injection is delayed for 2 hours after the inoculation—the effect is prophylactic, not curative. The activity of the serum persists at 57° C., but is lost at 70° C. and higher. Serum from one guinea-pig injected subcutaneously into another is fully protective or exerts a delaying effect; it is noteworthy that serum of an individual of species highly susceptible to experimental *B. diphtheriae* infection should be capable of affording some protection when injected parenterally into another animal of the same species infected with the particular organism. Normal horse serum is also protective in guinea-pigs injected with diphtheria toxin.—**W. A. Jolly**: Note on the electrogram of the frog's gastrocnemius reflexly excited. Records of the electrical change in the gastrocnemius when contraction is elicited reflexly by mechanical stimulation of the heteronymous foot, show that the response of the muscle is of the nature of a tetanus.—**J. S. van der Lingen**: Note on a cystoscopic irradiator and an ultra-violet light illuminator. The illuminator consists of a lens-system, of two quartz lenses and an iris diaphragm, whereby a field may be illuminated with any desired group of ultra-violet waves. One irradiator takes the form of a quartz-rod or tube shaped like a cystoscope, and the illuminator, by which rays are passed into the organs to be illuminated. The rays pass out only at the spherical tip. The other form consists of an exhausted tube bent into the form of a cystoscope, with a bulb at the external end containing a small quantity of mercury. Carbon-monoxide is introduced into the tube by heating, and this causes the mercury to radiate at a low temperature, when a high-frequency field oscillates in a helix placed over the external end of the tube.

SYDNEY.

Linnean Society of New South Wales, May 31.—Mr. G. A. Waterhouse, president, in the chair.—**G. D. Osborne**: The geology and petrography of the Clarencetown-Paterson district. Pt. 1. The descriptions are based upon an exhaustive survey of about 200 sq. miles containing rocks of the Burindi Series, Kuttung Series and the Cainozoic System. It is suggested that the Kuttung Series be divided into a basal stage, a volcanic stage, and a glacial stage in consequence of modifications found in the general sequence, the most important of which is the discovery of glacially-produced rocks on a much lower stratigraphic level than hitherto recognised. Five detailed sections of the volcanic stage are described. The work confirms the broad stratigraphical succession as given by C. A. Sussmilch.—**G. F. Hill**: Descriptions and biology of some North Australian termites. Four new species and two hitherto undescribed castes of the genera Eutermes and Hamitermes are described.—**J. B. Cleland**: A second bird census.—A census of the numbers of species and individuals observed on a series of journeys in various districts. The districts covered are southern coastal Queensland, Blue Mts., N.S.W., South Western Plains, N.S.W., Adelaide and Renmark Districts, S.A., and the Central Northern District, S.A.

Royal Society of New South Wales, June 7.—Mr. C. A. Sussmilch, president, in the chair.—**A. R. Penfold**: The isolation and identification of the acid bodies produced by the oxidation of piperitone by means of potassium permanganate. The ketone used was from *Eucalyptus dives*, and three acids were identified.—**M. Henry**: The incidence of anthrax in stock in Australia. Introduced originally about eighty years ago, anthrax attained serious proportions in certain districts, but during the last thirty years there has been a decline in the area infected. The disease has always been definitely localised. It was introduced near Sydney and carried inland and into Victoria but then disappeared from its original areas. At present most of the coastal districts, the tablelands and the Western Division of New South Wales are anthrax free. The real anthrax country consists of a belt in the western slopes; in Victoria there is a similar belt. Queensland is free, and possibly was never affected, and in the rest of Australia the disease is negligible. The season of greatest danger from anthrax is the summer and early autumn. The mortality from it is not heavy. There is an inhibitive factor which has prevented anthrax becoming more widespread. Among human agencies the controlling factors have been vaccination, quarantine, destruction of carcases by fire, breaking up of large estates, and substitution of agricultural for pastoral activities. Contaminated soil is generally the source of infection; infected feeding-stuffs, the common source of infection in England, do not operate.—**E. Cheel**: (1) Notes on the species of *Darwinia Homoranthus*, and Rylstonea in the states of New South Wales, Victoria, South Australia and Queensland. The plants are known as "Fringe Myrtles" or "Scent Myrtles," and are said to be of importance on account of the essential oil contained in the leaves. The plants known as *Darwinia taxifolia* are very variable and great care is necessary in the selection of material if pure grades of oil are required. Plants originally collected at Rylstone and given the name Rylstonea are probably forms of *Verticordia darwinioides*. (2) Notes on *Melaleuca linariifolia* and *Melaleuca trichostachya*. These species are commonly known as "Tea Tree" and "Tee-doo" respectively, and are also said to be of importance on account of the essential oil contained in the leaves.

Radio Broadcasting in Great Britain.

THE delay which has arisen in connexion with the inauguration of the proposed provision of a comprehensive radio broadcasting scheme in the British Isles has caused questions affecting the policy the Government should pursue in relation to broadcasting to be widely ventilated, and has, at the same time, directed attention to the great variety of interests that are involved in this matter. In view of the immense importance of radio telegraphy to-day in connexion with measures affecting national defence, and of the fact that this means of communication is easily susceptible of interference from accidental causes as well as those of wilful design, it is the duty of the Government to ensure that the radio interests in its own care shall be properly safeguarded in the new situation which has come into existence in the wireless field.

Hitherto the authority and powers under which the Government has exercised control in relation to radio-telegraphy are those which it has derived under the Wireless Telegraphy Act, 1904 (4 Ed. 7, c. 24)—hereinafter referred to as the principal Act—a temporary Act which was placed on our Statute Roll a very few years after the practical utility of radio telegraphy was first demonstrated, and has since been re-enacted in its original form from time to time as required. With the progress of time the need for governmental control in this field has in no way abated. Early in this year, about the same time that broadcasting first prominently attracted public attention, the Government took steps to strengthen its position by introducing the Wireless Telegraphy and Signalling Bill (12 & 13 Geo. 5—No. 148) in the House of Commons: therein provision is included for placing the principal Act permanently on the Statute Roll and, at the same time, for greatly enlarging the powers hitherto enjoyed by the Postmaster-General. Under these new provisions the Government will undoubtedly possess extremely large powers, but probably not larger than are required to enable it effectively to cope, in the general interest of the public, with the wireless situation in this country. It is unfortunate, then, that a suspicion should have arisen in some quarters that the new powers may possibly be misused by the Government in their application to broadcasting; particularly is this so as many conflicting interests are involved in connexion with the putting into operation of broadcasting services, and therefore, in pursuing its policy, the Government needs to secure the fullest confidence of the several groups affected.

Indications have already been given as to the policy

which the Government intends to follow with regard to certain aspects of broadcasting. The decision of the Government to leave this branch of wireless activity in the hands of private enterprise to develop, has been widely welcomed: however, fears have been expressed lest, in giving effect to its policy under a licensing system, the Government may allow an industrial monopoly to grow up. It has to be borne in mind that the situation under discussion is altogether an exceptional one, and that although a complete monopoly cannot be tolerated, on the other hand, as is the case with ordinary telegraphy and telephony, and, indeed, with many other public utility services, so in the case of radio broadcasting, the field is not one which lends itself to unlimited competition; for, on purely technical grounds, a limitation has to be placed on the liberty of free competition in those cases where the radiation through space of electro-magnetic waves for signalling purposes is involved.

This latter point requires to be emphasised, as a proposal has been seriously put forward that, in spite of the grave risks of mutual interference incurred thereby, full liberty of action should be permitted to those whose wish it is to develop and trade in radio broadcasting, rather than that a complicated system of licences and supervision should be introduced But full liberty of action is not feasible here: radio broadcasting cannot, on the transmission side, be conducted untrammelled by bureaucratic restrictions. The removal of such restrictions would not only defeat the aims of those who are seeking to establish useful, efficient and continuous broadcasting services in the British Isles, but would also, at the same time, put in serious jeopardy the radio communication services established in connexion with our national defence arrangements, as also the commercial services already in existence. For practical reasons, it is found necessary to lay down a definite upper limit to the number of radio transmitting stations which may be erected within a particular region. In the British Isles, the number of radio services of the several kinds connected with the fighting services and required for commercial purposes are already so great, that a central governmental authority has had to be created in order effectively to regulate the situation: it determines and allocates the radio wave-lengths that shall be utilised for particular purposes.

It is on the advice of this authority that the Government will, so far as the technical aspects of the situation are concerned, be obliged to act. In the matter of competition there are, of course, apart from the technical considerations referred to, financial aspects also which have to be brought under review. Normally it certainly is not the function of the Government to attempt to control the financial side of a private enterprise. However, so far as broadcasting is concerned, the Government is committed, *nolens volens*, to a certain measure of control of the organisations about to be licensed for this purpose; therefore, so long as everything is done to allow of the fullest amount of competition permissible in this field at the present time, and to admit of an increase of this competition in the future should technical and other considerations permit this safely to be done, it would not be unreasonable, at the present juncture, for the Government to exercise such further control as may be required to prevent anything being done the inevitable result of which would be the almost immediate destruction of a part of the capital of the investing public. On the other hand, by playing a part, as is proposed to be done by the Postmaster General, in the framing of the articles of association of the companies which it is intended to license for providing broadcasting services, the Government is likely, at some future date, to be deprived, wholly or partially, of its liberty to modify its policy in relation to competition should this be feasible, and desirable in the public interest, and it may thus lay itself open later to the charge of having allowed a monopoly to come into existence. It is at this stage that care should be taken by the Government to guard against entanglements which may afterwards prove embarrassing.

In the case of receiving apparatus the technical situation is relatively a simple one, and there is every reason for permitting the fullest competition in dealings connected therewith. It is desirable, therefore, that individuals wishing to possess such apparatus should have the greatest latitude allowed them in procuring what they want. Announcements have appeared that the types of apparatus to be used in connexion with broadcasting must conform to certain technical standards approved by the Post Office: if this merely means that the Post Office will issue a general specification, no objection can be taken. However, if it is intended that manufacturers must submit to the Post Office for its approval the designs of the apparatus they propose to put on the market for broadcasting, a serious mistake is being made alike from the manufacturers' point of view as of that of the Post Office, which will thus be saddling itself with a responsibility that it should seek to avoid. In the interests of all parties, it would seem best that the sale and purchase of wireless receiving apparatus should be carried on in these islands on the customary commercial lines free from restrictions of all kinds. It follows, therefore, that whoever may so desire should be permitted to make use in his or her broadcasting receiving installation of any home-made apparatus, provided that the same complies with the general technical requirements laid down officially.

It has been announced that the Postmaster-General is in favour of subsidising the organisations which are to be licensed for broadcasting purposes out of fees to be collected on the licences issued in connexion with wireless receiving stations. The situation is one which requires to be carefully handled, if mischief is not to be done. The authority given to the Postmaster-General to grant and renew licences in connexion with radio receiving apparatus exists primarily, not for revenue-raising purposes, but for that of effecting the registration of wireless installations of every kind; a step which is necessary as a measure of police precaution and also for facilitating control over all individuals using radio receiving sets. Since the law requires every person with a wireless installation to take out a licence, the charge for the same should be kept as low as possible. At the same time, it is reasonable that those who desire habitually to avail themselves, for one reason or another, of broadcasting services should be expected to contribute towards the cost of the same: strictly, this contribution should depend upon the extent of the user. The situation is one that lends itself to treatment by the grouping of the licences, on some practical basis, into two easily distinguishable categories, and by a differentiation in the charges to be levied on the licences in these two categories.

Now, broadcasting is essentially a luxury demand, and it has to be borne in mind that there are to-day, and will always be, many owners of licensed wireless installations who are not desirous, as a practice, of making use of broadcasting services. For this reason, anything in the nature of a general levy on all wireless receiving stations must be avoided. On its merits, broadcasting is deserving of the fullest encouragement and the greatest assistance which the Government can give it, alike in the interests of those who seek amusement therefrom, of the research workers in this field, and of the electrical industry. It seems improbable that any sum likely to be raised at the present time by fees on the grant and renewal of licences will go anywhere near providing the contemplated annual outlay on the broadcasting scheme which has been projected. It has been estimated that an outlay of 180,000*l.* per annum [2] will be involved in connexion with the proposed broadcasting stations. Now, there are at the present time in this country some 10,000 holders of licences for wireless receiving installations. In view of the relatively high cost of providing complete receiving installations, an increase in the number of licences may, in these days of trade depression, be a slow matter; but assuming that an immediate increase may multiply their number tenfold, even so, approximately 2*l.* per annum would, on a flat-rate basis, have to be levied on every licence, in addition to the registration fee, if the whole annual cost of the broadcasting stations is to be met in this way. There is, however, a serious risk that an annual contribution on this scale may have the effect of retarding materially the rate of the growth in the number of private wireless installations.

In these circumstances, it would seem that the licensed organisations will be well advised to endeavour to raise the annual revenue they require largely from audiences attracted to public entertainments promoted and run under their auspices: evidence exists tending to show that large audiences can be attracted to broadcasting entertainments of a high class. The licensed organisations can, of course, at the same time, raise additional revenue by hiring out wireless receiving installations for entertainment purposes, by sales of apparatus outright, and by other means. It is in relation to the carrying out of this wider policy, which caters for the needs of all classes interested in radiotelegraphy, that the Government can best help in popularising broadcasting and aid in promoting the commercial success of licensed organisations rather than in the attempt to subsidise them out of moneys raised by means of fees charged on licences, the amount of which may, more than likely, prove extremely disappointing. For example, the Government can, on the technical side, help the licensed organisations materially by allotting to them the necessary number of suitable radio wave-lengths to enable them to carry out their programmes, and in many other incidental ways: it can also to some extent afford them assistance on the commercial side by causing all applications for entertainment licences to be collected by them for transmission to the Postmaster General, a course the adoption of which would provide the licensed organisations with opportunities for selling broadcasting services, whilst at the same time promoting genuine competition in this field.

In connexion with broadcasting, other rights are threatened, such, for example, as copyright and patent right. In all the circumstances of the present situation, it behoves the Government then to keep itself as free as possible from responsibility in connexion with the details of the radio broadcasting services. This it will do so long as it confines its rôle to that of a licensing authority exercising general control and supervision over the purely wireless situation, and by allowing, in collateral matters, the old doctrine to prevail, that where the likelihood of the invasion of the legal rights of others is involved, every subject in the realm acts at his own peril and must be held personally answerable for his own deeds to him who establishes in due course of law that he has suffered an injury from an actionable wrong at the hands of another.

University Education in London.

The University of London (History, Present Resources and Future Possibilities). By Sir Gregory Foster. Pp. 48. (London: University of London Press, Ltd., 1922.) 1s. 6d. net.

THE Provost of University College has been well advised to publish in the form of a pamphlet, attractively printed and illustrated, the two lectures delivered at the College in February last, together with the speech of the president of the Board of Education (Mr. Fisher) at the conclusion of the second lecture. A less ambitious title might perhaps have been chosen, for in effect the lectures are a closely reasoned apology for the Bloomsbury site and for the University policy which it represents. At the outset, the popular illusion that University education in London is to be concentrated entirely in one quarter is examined and dismissed The sites alone of the thirty-six Colleges of the University occupy no less than 212 acres and their students number 21,600 Their halls of residence account for 7½ acres and their playing fields for another 215 acres, making a grand total of 434½ acres. To bring together these vast educational resources would be a prodigious undertaking extravagant (a "wanton waste" as the Provost says), impracticable by reason of the necessary contiguity of the medical schools to their hospitals, and undesirable in an educational sense. Other less fortunate Universities have discovered that it is impossible to educate in crowds. The Provost's arguments against carrying the "concentration" idea too far are complete and unanswerable.

One asks at once why if a large dose of the medicine is fatal, a homœopathic dose should be beneficial—in other words, why the Government should urge so strongly the removal of King's College to the Bloomsbury site "It is," says the Provost, "for the obvious reason that King's College on its present site, delightful as it is from many points of view, cannot grow and extend according to its needs." This argument is hardly relevant, for there are other parts of London than Bloomsbury where King's College could grow if that is what it wishes to do. The question of the *optimum* size for a college is involved; and there are other ways of growing, it may be suggested, than in size and numbers—in efficiency, for example, or by planting out part of its work as King's has done already in the case of its Household Science Department at Campden Hill. The impression left on the mind of the reader of these discourses must be that the King's College question is not discussed with force or conviction.

There is a peculiar habit in University circles in London of continuing the argument after a conclusion has been reached. From this point of view the Provost's carefully compiled statistics in favour of the Bloomsbury site will fortify the loyal forces in the guerilla warfare which is now being waged with vigour and persistence. Of the total of 21,634 students in the Colleges of the University, no less than 16,764 are in Colleges within two miles of the Bloomsbury site, whereas the corresponding figure for the rival Holland Park site is only 1520. The number outside the two-mile radius of either site is 3306. Whether the two-mile radius was chosen because of the distance covered by the 1*d* bus fare of a happier generation, we cannot determine; but we may fairly ask why the University quarter should be within this reasonable distance of the students, seeing that except for compulsory attendance at examinations they have in recent years found no pleasure in visiting the University headquarters On the only occasion on which the present writer remembers to have seen a thousand London students in one room, their object in coming together was to denounce the existing constitution of the University!

On this question the Provost maintains a strange silence He fails to stress the need which exists in London for the active encouragement of all those social, athletic, and extra-academic influences which make for the development of students' personality as distinct from intellect The Bloomsbury site should provide these facilities as far as practicable in the form of dining-halls, clubs, hostels, accommodation for debates and meetings of extra-academic societies, theatres, concert-rooms, art galleries, museums, gymnasia, fives courts, swimming baths, churches, and mosques! Unless something can be done on these lines, the whole discussion is meaningless from the point of view of the students regarded as human beings and not merely as statistical units.

For administrative purposes and for ceremonial and public meetings of all kinds, the need for a central position is paramount and incontestable. Busy public men, administrators, and teachers who do voluntary work as members of University Committees may reasonably demand that their sacrifice of time and money in travelling shall be reduced to a minimum. A few weeks ago some five hundred graduates attended a meeting of Convocation at South Kensington for the purpose of electing a new chairman. At the lowest computation 10*l.* extra was spent in travelling to South Kensington as compared with, say, Bloomsbury; more important and serious, the meeting must have been less representative because of the inability of graduates living or working on the remote side of London to attend. How any person of common sense or knowledge of London can argue that South Kensing-

ton or Holland Park is conveniently situated for a University quarter passes comprehension.

It would be unfair to expect in the course of two lectures a full exposition of University policy; but there appears to be some lack of consistency, possibly more apparent than real, between the criticism of pre-1900 higher education in London when "each college made its own plans and did its own work in the best way it could" and the current demand that, a teaching University having at last been established, certain Colleges shall be given the status of "Dominions" enjoying Home Rule within the University. If University and King's Colleges were set up cheek by jowl on the Bloomsbury site, the need for co-ordination by some independent and impartial authority would cry out to heaven. The Provost is on surer ground in pleading for "as much concentration in the University Quarter as is practicable," especially in respect of "all the new post-graduate institutes," and our only criticism of this proposal is that a more comprehensive term than "post-graduate institutes" should be used. In addition to post-graduate institutes, there is need for a number of schools or institutes of a specialised character, *e.g.* for law, music, drama, journalism, and military science, to specify only a few subjects for which at present provision is not made or is inadequately made within the University. As an instance of a post-graduate institute, the new scheme for an Institute of Public Health is cited, and it is gratifying to find that the demand for Collegiate Home Rule is not in this case interpreted by the Provost in the sense of "what we have we hold." "We have a department [of Hygiene] in this College, the oldest in the country, but it is inadequate to meet the needs of London; and we should be prepared to see that department, and all the still smaller departments in the other Colleges, merged into one great institute. That is the kind of development which will be helped by the concentration in Bloomsbury."

Towards the conclusion of the lectures, the Provost pleads for "the necessary spirit to pull and work together" in order to substantiate the vision of a great University of London which he has somewhat faintly adumbrated. These wise words should not be received in a derisive spirit. No one will suppose that University College has attained its present great prestige without a struggle, or that on certain occasions its rivalry with other Colleges may not have taken a combative form. The important thing to ensure, as the Provost suggests, is that this rivalry, unavoidable and even desirable within limits, shall be as free as possible from selfishness—"particularism" is the polite academic word—with the greater glory of the University always in view, magnanimous, void of envy, malice, and intrigue, and of that perverted form of academic freemasonry which suspends private judgment and exalts College loyalty. The alternative is constant suspicion and bitter, often unreasonable, opposition to progress.

A brief reference must be made in conclusion to Mr. Fisher's speech delivered at the end of the second lecture. He found himself in "full agreement with the admirable doctrine contained in the address." The University of London was a species by itself.

"The Government, four years ago, made an offer of the Bloomsbury Site to the University of London. That offer has been accepted by the University. The Government do not propose to make another offer, and if the University does not like the site, well, it can return it to the source from which it came. I have no doubt the Chancellor of the Exchequer will appreciate its generosity."

The limit to the number of students who could be educated at Oxford and Cambridge had been reached, and London must be prepared to receive a great influx of students, particularly

"from the Dominions, from India, from the Crown Colonies, from the United States of America, and from the allied Powers of the Continent." You must concentrate in one part of London "not *all* the teaching power, but an impressive proportion of the teaching power," and that was "the principal object which the Government had in view in suggesting an arrangement under which King's College could be brought into close proximity with University College." And as last words he said: "Let those who are anxious for the future of London University, from whatever angle they may have hitherto viewed London University problems, let them concentrate on the endeavour to create upon the site a noble series of buildings, worthy of the reputation of the University, worthy of its past, and adequate to the great destinies which await it."

T. LL. H.

Antarctic Foraminifera.

British Museum (Natural History). British Antarctic ("Terra Nova") Expedition, 1910. *Natural History Report. Zoology,* Vol. 6, No. 2. *Protozoa,* Part 2: *Foraminifera.* By Edward Heron-Allen and Arthur Earland. Pp. 25-268 + 8 plates. (London: British Museum (Natural History), 1922.) 30*s.*

STUDENTS of natural history in its wider aspects will welcome the appearance of this memoir on the Antarctic Foraminifera of the second Scott Expedition—a notable contribution to the series of reports which have resulted from the *Terra Nova* Expedition. The authors state that the material collected during the expedition was placed in their hands seven years ago, and that the delay in publication has been due, not

only to the difficulties of biological research in war-time, but also to the method of preservation adopted for most of the dredgings containing foraminiferal specimens. The collectors appear to have put unwarranted confidence in formalin, "than which no more unsatisfactory medium for . . . Foraminifera can be imagined." Messrs. Heron-Allen and Earland have been compelled, therefore, to expend much time and trouble in cleaning the material entrusted to them so as to render it at all suitable for study, and they "can only review the results as a tantalising sketch of the possibilities which would have attended upon an ample supply of properly collected Antarctic material." Nevertheless, the authors are able to record 650 species and varieties of these fascinating Protozoa, of which 46 are new to science.

In looking through the systematic list, which occupies by far the greater part of the memoir, the student of distribution cannot but be impressed by the wide range of many of the types. Species recorded here from the far south are identical with those, already enumerated in lists by the same authors, of Foraminifera from the North Sea, and from the Atlantic waters around the shores of Conacht. Several types are common to Arctic and Antarctic regions, but these are almost all pelagic forms, and capable of the most extensive migrations. The only exception, *Globigerina pachyderma*, Ehrenberg, with its "curiously thick-walled" shell, is "the typical Globigerina of Arctic deposits," reaching its southern limit about the Faeroe Channel. Nevertheless, the authors do not consider that its presence in the Antarctic Ocean affords any support to the once-popular "bipolarity" theory of specific origins. Apparently *G. pachyderma* is "a local variation" of *G. dutertrei*, d'Orbigny, a transition from the one form to the other being clearly demonstrable as dredgings from more southerly stations are examined. This transition is supposed to be "induced by conditions of temperature," and the authors believe that "the same gradual transition [from *G. dutertrei* to *G. pachyderma*] which we have described in the Antarctic could be traced in the Arctic and temperate seas."

Systematic students of the Foraminifera will be especially interested in the number of hyaline species of which arenaceous isomorphs are described—for example, *Bifarina porrecta* (Brady), *Bolivina punctata*, d'Orbigny, and *Rotalia soldanii*, d'Orbigny. The authors express their agreement with Butschli, Fauré-Fremiet, and other recent workers at the order, in considering that the existence of such isomorphs—the formation of an arenaceous instead of a calcareous test due to some obscure physiological reaction—may necessitate ultimately a revision in the classification of the Foraminifera. "We do not think the time has yet arrived to abandon the generally accepted, if artificial, system of Brady, which, with its modifications, is followed in this Report. But we have endeavoured to clear the way towards a proper zoological allocation of the Lituolidæ by refraining wherever possible from the creation of new arenaceous species, and retaining our new arenaceous forms in the genera to which they naturally belong."

Among the newly described forms the genus Dendronina, referred to the Astrorhizidæ, comprising two New Zealand and two Antarctic species, is noteworthy. The test is built of fine mud, sand-grains, and sponge-spicules, and the sessile *D. arborescens* assumes a complex branching habit, attaining a height of 5 to 6 millimetres. The authors believe that the genus may be represented also in tropical seas (Indian Ocean). *Polytrema miniaceum* (Pallas) was found in great abundance in the New Zealand area, at one station "practically every solid organism" being "more or less covered with it." It is a sessile foraminifer of very wide range, and the authors have made a special journey to Corsica so as to study the species in life in Mediterranean waters. The organism in its early free stage settles on some object, wherewith it gains connexion by thrusting out protoplasm from its under surface and forming "a thin layer of incrusting chambers" The protoplasm subsequently streams out from these, surrounds the young spherical test, and constructs a wall of small chambers which overgrow and envelop the latter. Finally the characteristic branching, arm-like processes grow out. The occurrence of siliceous sponge-spicules inside the chambers of the Polytrema has given rise to much discussion; the authors have observed sponge and foraminifer "close together and approximately the same size," and do not altogether reject the possibility of a true symbiosis.

In order to reduce the cost of publication, the authors have restricted to a minimum their synonymic references. The eight plates illustrating the memoir have been admirably drawn by Mr. M. H. Brooks and are excellently reproduced. All the workers concerned may be heartily congratulated on the results made known in this most recent outcome of Antarctic exploration and research.

G. H. C.

Water Underground.

Nouveau Traité des eaux souterraines. Par E.-A. Martel. Pp. 838. (Paris: G. Doin, 1921.) 50 francs.

IN M. Martel's treatise, stress is naturally laid on what he has styled "spelæology." For him, subterranean water moves in a fascinating world of caves. The conception of a general water-table in

permeable rocks does not appeal. His conclusions as a follower of water by sheer hard climbing and exploration underground are supported by the very varied results of borings made near one another in beds regarded as porous by the engineer. M. Martel believes, with much justice, that subterranean rivers do not etch out their own way; they are determined by pre-existing crevices, the *diaclases* of Daubrée. In the case of limestone, solution obviously widens the original fissure; but it must have been generally recognised that the long-continued dominance of the joint-system is again and again revealed in the plans of sinuous caves.

M. Martel, however, does not give geologists much credit for observing a relation between the direction of surface-streams and the fissured structure of a country; but we cannot help remembering the account of the Drava and Gail system in the first volume of Suess's "Antlitz der Erde," and the exposition by Molyneux and Lamplugh of the Batoka Gorge of the Zambezi. In the case of Mosi-oa-tunya, however, M. Martel seems satisfied with the somewhat catastrophic views of Livingstone. We must admit that an examination of our ordinary text-books reveals an unfortunate silence on this question of fissures and stream-erosion; but surely M. Martel is inclined to exaggerate (p. 42) the differences between his views and those of colleagues like Lugeon, Kilian, and de Martonne. He is accustomed to move adventurously in narrow rift-like ways, along the floors of ravines and their counterparts underground, but he cannot wish us to return to the antique view of valleys as gaping fissures in the crust. On a tilted peneplain the courses of streams are at first uncertain; they are controlled merely by the general slope. When they have worked down into the surface of solid rock, they at once begin to be guided by the joints, the lines of weakness. The walls of the ultimate valleys are due to erosion; the general ground-plan is often determined by that of the joints, the walls of which are practically in contact until the streams begin to work.

The surface-waters then cut downwards. By seepage they become subterranean, and the *diaclases* prove still more effective in the underworld. The details of caves and of disappearing and reappearing streams are never monotonous to M. Martel; but the frequent photographic representation of them may pall a little on the geological or engineering reader. We must admit that the pictures here given, to the number of three hundred, are fascinating and often very impressive. In some cases, as in those of the cañon of Olhadibie in the Basses-Pyrénées, they result from very recent exploration.

The discussion of the origin of water in the Chalk (p. 366) raises important engineering considerations. Mr. R. L. Cole has recently dealt with this matter as regards the south of England ("The Power User," June 1922, p. 97), and he treats the body of the Chalk as providing little opportunity for flow. M. Martel, in his descriptions of "lapiaz" or "lapiés" (p. 531), shows well how water penetrates a limestone surface and how it proceeds to ramify below. His remarks on the use of the divining-rod (p. 749) are philosophic and reserved; he looks for a very extended series of trials made on a consistent plan. The power of divination, if it exists, resides in the operator and not in the instrument used. He shows, among other interesting matters, how the sinking of artesian wells was known to dwellers on the edge of the Sahara centuries before Moorish engineers were invited to find water in Artois. The ease with which subterranean water may be contaminated is attested by grim instances (p. 767) of the slow decomposition of corpses interred on the battlefields of 1914–18, and by the infection during a whole year of the spring of Gerbéviller in Lorraine.

GRENVILLE A. J. COLE.

Statics, Dynamics, and Hydrodynamics.

(1) *Elementary Statics of Two and Three Dimensions.* By R. J. A. Barnard. Pp. vii+254. (London: Macmillan and Co., Ltd., 1921.) 7s. 6d.

(2) *Theoretical Mechanics: An Introductory Treatise on the Principles of Dynamics, with Applications and Numerous Examples.* By Prof. A. E. H. Love. Third Edition. Pp. xv+310. (Cambridge: At the University Press, 1921.) 30s. net.

(3) and (4) *Idromeccanica Piana.* By Prof. Umberto Cisotti. Parte Prima. Pp. xii+152. Parte Seconda. Pp. viii+155-373. (Milano: Libreria Editrice Politecnica, 1921.) Lire 24 and 32 respectively.

(1) PROF. BARNARD'S new book makes an excellent text-book for the higher years in pass degree courses and for the first part of honours courses in applied mathematics. The scope is that generally expected, a chapter on forces in three dimensions being included. In treatment the book is orthodox and safe, so orthodox in fact that centres of gravity are left to quite a late chapter, as if the finding of centres of gravity were an aim in itself. The proof of the vector property of couples is very effective.

A chapter is added on vectors in space, use being made of the vector notation, and the student is referred to the author's "Dynamics" for a fuller treatment. The modern student of mechanics and physics cannot afford to be quite ignorant of vector methods and notation, and Prof. Barnard is performing a useful

service by including them in his books, even if only in the form of an afterthought.

(2) Prof. Love's "Theoretical Mechanics" is a book that serious students of dynamics cannot be without: the discussions of the principles are illuminating, and the collections of examples are useful to both teacher and pupil. Only a few changes have been made in the recently issued third edition. Perhaps it is permissible to suggest that the book would be immensely more useful if it partook of the nature of a text-book, and included a much larger number of worked examples. The student's main difficulty in dynamics is not in learning the comparatively restricted number of ideas and methods given in the usual honours courses, but rather in obtaining the necessary experience for using these ideas and methods successfully in the problems presented by nature. By far the most effective help that can be given him is that contained in a judiciously selected and carefully graduated series of worked problems, where the efficiency value of each process is made evident.

As the author emphasises the importance of the fundamental principles, the volume would be the right place for a brief account of relativity in dynamics. To leave this latest phase of modern scientific reform to the physicist and the philosopher is a mistake that applied mathematicians should endeavour to counteract.

Publishers no doubt know their business and do not need the advice of academic men. A protest must nevertheless be raised against excessive prices. The price of this new edition will prevent its sale among just those young students whose mechanical ideas the author wishes to influence.

(3) and (4) The study of two-dimensional problems is of great interest in several branches of applied mathematics, as, for instance, in potential theory, electricity, and hydrodynamics. It often happens that when a three-dimensional problem of importance cannot be solved, the two-dimensional case is amenable to modern mathematical methods and its solution sheds much light on the general problem. This has been the case particularly in hydrodynamics.

The present volumes are the first two parts of a treatise on two-dimensional hydrodynamics. Part I. gives the theory of the complex variable and conformal representation, which is followed by a statement of the equations of motion of a fluid in two dimensions. Problems with boundaries consisting of free stream lines only, and with boundaries consisting of fixed barriers only, are then discussed. Part II. deals with jets and other problems, involving both fixed and free boundaries, while Part III. will deal with wave-motion.

Of the different types of problems discussed by Prof. Cisotti, perhaps the most interesting is that of discontinuous motion of fluid past a fixed barrier—a problem that has some bearing on the modern subject of aerodynamics. When the barrier is plane, and the motion is assumed to be irrotational, with free stream lines, the problem has been solved by the use of what constitutes one of the most elegant processes of mathematical reasoning. Curved barriers, however, have so far defied solution, except in the sense that when a solution is suggested one can obtain equations which define the barrier appropriate to the solution. The problem of the curved barrier may almost be described as one of the classical problems of hydrodynamics. Several interesting cases have been discussed, in particular by Prof. Cisotti himself, Villat, and others.

The ordinary text-book process of solving two-dimensional problems in hydrodynamics is to seek a relation between the complex variable that represents the geometry of the actual motion and the complex variable involving the velocity potential and the stream-line function. An intermediary variable, which is essentially representative of the velocity vector, is often useful. In dealing with discontinuous motion past barriers consisting of plane surfaces, a further intermediary variable is needed, based on the Schwartz-Christoffel transformation: the problem is then reduced to quadratures.

For curved barriers, however, this is insufficient, and a new type of transformation has been found necessary. The essential idea of this transformation is to make the barrier correspond to a semicircle in a new Argand diagram. The general solution of the problem is then defined in terms of a Taylor expansion, and the choice of the coefficients in this expansion determines any particular curved barrier. Elegant formulæ exist for finding the pressure components on the barrier, and the line of action of the resultant pressure, but an explicit statement for the latter has not yet been published.

This process, due to Levi-Civita and others, can be made to yield numerical results of considerable interest. Brillouin has given the working for a set of barriers defined by a certain choice of the coefficients in the above-mentioned series. Further, by a process of approximation, circular and elliptic barriers admit of numerical solution.

Prof. Cisotti's résumé of the progress in this problem during the last fifteen years is masterly, and of great use to researchers in the subject. It seems, however, that the footnote on p. 179 is based on a misapprehension. Brillouin has given the conditions that must be satisfied if the free stream lines are to have finite curvature where they leave the barrier. The author urges that these conditions are not necessary. He is right, but Brillouin does not mean that these conditions

are to be satisfied always. As a matter of fact, the problems in which Brillouin's conditions are satisfied are those which have the greatest bearing on aerodynamical research. Further, Brillouin's conditions can be used to elucidate the rather puzzling question of the difference between barriers which are defined by the same mathematical curves, but of different extents, as *e.g.* circular barriers of different angular extents.

These two volumes can be highly recommended to all who are interested in recent developments in the mathematics of two-dimensional hydrodynamics.

S. BRODETSKY.

Our Bookshelf.

Register zum Zoologischen Anzeiger. Begründet von J. Victor Carus. Herausgegeben von Prof. Eugen Korschelt. Band xxxvi.-xl., und *Bibliographia Zoologica*, vol. xviii-xxii. Pp. iv+695. (Leipzig: Wilhelm Engelmann, 1922.) 280 marks.

ALL who have had occasion to use the bibliography which is issued with the "Zoologischer Anzeiger" know that much trouble and loss of time are involved in consulting the volumes not yet indexed in one of the five-yearly "Registers." They will welcome, therefore, this belated volume, which indexes, mainly, the papers published from 1909 to 1911, including also a few from 1912 and a good many of earlier date which had previously escaped notice. It is compiled according to the same plan as its predecessors. Each paper is indexed under its author's name, with an abbreviated title and a citation of the volume and page of the bibliography where the full reference will be found. There are also cross-references under systematic names where these are mentioned in the title, or in the brief notice appended to the entries in the bibliography, and all new generic names are separately entered.

It was the opinion of Herr Heinrich in Mr. H. G. Wells's story of "Mr. Britling" that "the English do not understand indexing." It may be only because of this national defect that we find the plan of the "Bibliographia Zoologica" cumbersome and inconvenient as compared with that of our own "Zoological Record." The volume before us is only an index to an index. It requires us to take down at least one other volume from the shelf before we can find the reference we want. It includes neither a subject index nor a geographical index, and the systematic references are far from adequate for the needs of the systematist. All bibliographies, however, are useful, if only because none of them is perfect, and certainly no zoologist can afford to neglect the "Bibliographia Zoologica." At the present time, when the obstacles to the international diffusion of knowledge are only slowly being removed, the need for such works and the difficulties in the way of compiling and publishing them are alike great. It is to be hoped, therefore, that this volume will soon be followed by others cataloguing the literature of more recent date.

W. T. C.

Report of the Canadian Arctic Expedition, 1913–18. Vol. xii.: *The Life of the Copper Eskimos.* By D. Jenness. (Southern Party, 1913–16.) Pp. 277. (Ottawa: Department of the Naval Service, 1922.) 50 cents.

THE report of the Canadian Arctic Expedition, 1913–18, is planned to include at least sixteen volumes. This, the ethnographical volume, is the work of Mr. D. Jenness, a graduate of the University of New Zealand, who received his anthropological training at Oxford, and is already known as the author of an important book entitled "The Northern D'Entrecasteaux." Mr. Jenness lived for some years in the tents and snow-houses of the Eskimo, and though he says little of his personal difficulties, the companionship of his Eskimo hosts and their strange food must have been a trying experience. With the help of a devoted missionary, the Rev. H. Girling, who unfortunately died of pneumonia at Ottawa in 1920, he has been able to prepare a singularly valuable account of life in all its phases among the Copper Eskimos, whose headquarters are on the Coppermine River. Fortunately for them, this land lies in the track of the Great Caribou migration when the herds move northward in the spring. They are then able to collect stores of meat and skins, and from this and the seals and fish, which are abundant, their wants are supplied. Formerly their hunting was done with bows and arrows, but these are now replaced by rifles, and it would be well for the Canadian Government to consider whether the use of improved weapons should not be controlled in the interests of game preservation.

The book is full of curious facts and is illustrated by photographs and maps. "With the influx of traders and missionaries into the country the conditions of life are fast changing. Famine looms less in the foreground, but in its place European diseases are threatening the health of the communities, and bid fair to rival all other causes in their effect on the death-rate." The suggestion that a period of quarantine and medical examination should be enforced on all strangers entering the Eskimo territory certainly deserves serious consideration.

The Scope of School Geography. By Dr. R. N. Rudmose Brown, O. J. R. Howarth, and J. Macfarlane. Pp. 158. (Oxford: Clarendon Press, 1922.) 5*s.* 6*d.* net.

THE authors have briefly reviewed the scope of school geography, maintaining two dominant themes throughout, one the essential unity of the subject, the other the scientific character of its data and its methods. "Geography, properly speaking, has a definite view-point of its own and is not a mosaic of loans from other subjects." "The teaching of geography is no less the work of a specialist than the teaching of chemistry or history."

The authors have adhered, and for school purposes perhaps correctly, to the statement that geography may be regarded as the interaction between man and his environment; but even for the purpose of this book it might have been desirable rather to have stated the broader and deeper truth that geography has as its field the distribution of the interrelations of many phenomena of which human activities form but one.

In the chapters dealing with meteorology, biology, oceanography, and economics the relations of these subjects to geography and the material which geography can and must derive from them for its own study is fully discussed. On the subject of maps and map-reading the book contains excellent advice. "The practical study of maps must entail the art of map-reading." "The map must be interpreted."

Many will disagree with the authors' application of the term historical geography. Some historical events depend for their complete interpretation on a knowledge of geography, but this is not historical geography; it is merely history fully understood. It is possible, however, in theory at least, to reconstruct for each region the geography of past epochs and to see for that area not merely the evolution of its history, but what is much more comprehensive, the evolution of its geography. This is historical geography.

The book should do much to remove the many anomalies which exist in the school study of the subject.

Within the Atom: A Popular View of Electrons and Quanta. By John Mills. Pp. xiii+215. (London: G. Routledge and Sons, Ltd., n.d.) 6s. net.

WHAT can a scientific reviewer say about books like this on "popular science"? Mr. Mills, who has quite a competent knowledge of his subject, sets out to initiate those who have no knowledge of physics and chemistry (and apparently no intention of acquiring it) into the mysteries of modern atomic theory. Of course the task is utterly impossible. Scientific theories serve mainly to explain facts, and those who have no knowledge of those facts can grasp little of their real meaning. Such satisfaction as they can obtain must be wholly different from that of the earnest student, who, even if he admits the morality of an attempt to delude the laity into the belief that they can appreciate scientific work without serious study, can never be in a position to judge whether an author has been successful in tickling the palates of his readers in the manner they desire.

However, from the sale of similar works we imagine that there are some who will appreciate the mixed fare set before them. Very mixed it is, ranging from a conversation (in the spirit, but not the style, of the celestial dialogues of Faust) between the author, an electron, energy and the reader to a more or less sober discussion of the difficulties of interpreting X-ray spectra. Indeed we find a certain inconsistency in our author's attitude; if he is prepared to make such a concession to sensationalism as to assert that the nucleus is smaller than the electrons which it contains, he need not have boggled over many quite minor difficulties which seem to us to occupy a disproportionate space. But then, as we said, we are clearly not in a position to judge.

Sud-Bayern. Von R. H. Francé. (Junk's Natur-Fuhrer.) Pp. v+423. (Berlin: W. Junk, 1922.) M. 32 and 150 per cent "Valutazuschlag."

IT is pleasant to think that the State of Bavaria was not dismembered by the great European peace, and we regret that Dr. Francé's scientific guide-book could not extend a little northward, so as to include the palæontological treasures of Eichstatt and the cauldron-subsidence of the Ries. But the finest landscapes of the country await the traveller across the southern glacial plain. There is much, indeed, to detain him on the "Niederterrassenschotter" itself. Dr. Francé calls attention, for example, to the forest of Ebersberg, within easy reach for any botanist who visits Munich. Here the climatic change in modern Germany may be traced in the decay of the giant oaks in the eighteenth century, in the subsequent dwindling of the beeches, and in the present predominance of conifers, under which wild tulips grow. The site of Munich raises the puzzle of its apparent extinction in Roman times, though Roman roads run through it, based on predecessors built by Celtic engineers. The rapid rivers are themselves worth watching, as they stream from the Alps across the glacial deltas of the plainland. With this book as a companion, the naturalist will finally cross the old lake-floor to Partenkirchen, and will stand under the crags of the Wetterstein well content. G. A. J. C.

In the Heart of Bantuland. By Dugald Campbell. Pp. 313. (London: Seeley, Service and Co., Ltd., 1922.) 21s. net.

MR. CAMPBELL provides his readers with an abundance of good stories of big-game hunting, slave traders, and natives and Europeans whom he has met in his twenty-nine years of experience as a missionary. His travels range from the Katanga and Angola to the shores of Lake Nyassa. His use of the word "Bantuland," not merely in his title but in the text, may be misleading to the uninitiated, as he does not deal with all Bantu peoples, but only with those within the limits mentioned. Even thus he is not always sufficiently explicit in mentioning the tribe to which a particular custom or belief appertains. Many of the peoples with whom he deals are but little known, and his careful description of their culture is a useful addition to our knowledge. His account of secret societies of various types is worthy of note. Mr. Campbell gives to native character a tribute of admiration which is well deserved, as is shown by instances of self-sacrifice and bravery, while he has much to say of the political sagacity and instinct for government displayed by some of the tribes and their chiefs.

The Technique of Psycho-Analysis. By Dr. David Forsyth. Pp. viii+133. (London: Kegan Paul, Trench, Trubner and Co., Ltd., 1922.) 5s. net.

IN his book on the technique of psycho-analysis Dr. Forsyth deals, from the practical viewpoint, with a subject which is full of difficulties for the beginner in analytical work. The first chapter is devoted to a consideration of the analyst himself; the second deals with the conditions under which the treatment should proceed; the remaining four chapters discuss the actual analysis. Dream analysis is excluded as being too big a subject for discussion in such a book, and the reader is referred to Freud's "Interpretation of Dreams" for the study of this side of analytical treatment.

Dr. Forsyth gives much practical advice which is frequently omitted from literature on the theory and practice of psycho-analysis.

Letters to the Editor.

The Acoustics of Enclosed Spaces.

THE acoustics of enclosed spaces intended to hold large audiences is now receiving attention, and it is recognised that good conditions for distinct hearing can be obtained only by eliminating the reverberation due to reflection from the walls. Owing to the high velocity of the transmission of sound in nearly all solid bodies, the angle at which total reflection begins is small; for oak wood it is about 6°, and for glass as low as 3°. Unless the wave-front is therefore very nearly parallel to a wall it cannot penetrate and is sent back into the room. The simple and partially effective method of deadening the reverberation by covering the walls with a highly porous material, or woven stuffs, is difficult to apply in large spaces, and a more hopeful solution of the problem seems to me to lie in the discovery of a substance that can be used for the exterior lining of walls and has a velocity of transmission not far different from that in air.

Unfortunately our knowledge of the velocity of sound in different materials is very scanty. I am not aware that the acoustical properties of the substances most commonly used in buildings, such as stones, brick, and mortar or plaster of Paris, have ever been examined. My suggestion is to look for a suitable material which is transparent to sound and can be backed by highly porous matter which will absorb the transmitted vibration. If necessary, a series of alternate layers may be introduced. In referring to the tables of Landoldt-Bornstein I find that the substance which has a velocity of transmission for sound nearest to that of air is cork. This might be taken as a starting point for further investigation, but there are great gaps and inconsistencies in the tables.

It is to be remarked that at nearly normal incidence, so long as no total reflection takes place, the posterior surface of the wall diminishes very considerably the intensity of the reflected sound. This is illustrated by the analogous problem in the theory of light. Applying the relevant equations (A. Schuster, "Optics," p. 71) to normal incidence we find for the reciprocal of the intensity of a wave transmitted through a wall $1+\pi^2(1-\mu^2)^2e^2/\lambda^2$, where e is the thickness of the wall, λ the wave-length in air, and μ the refractive index. It is here assumed that the thickness of the wall is small compared with the wave-length measured inside the wall, which will nearly always be the case. For wood the refractive index is about ·1, and for stone it will probably be of the same order of magnitude. Applying the equations and assuming the wave-length to be 250 cm. in air, representing a frequency of 130, we find that a wall one metre thick would transmit 86 per cent. of the incident sound at normal incidence, and this would be increased to 98·5 per cent. if the thickness be reduced to 10 cm. Apart from absorption, it is to be expected that stone walls are fairly transparent to sound falling normally upon them. But, as has been said at the beginning, sound incident at angles slightly inclined to the normal is totally reflected.

Some interest attaches to the cognate problem of avoiding the transmission of sound from one room to another. I am not referring to the construction of sound-proof spaces of comparatively small dimensions, such as telephone boxes, where the use of absorbing materials is permissible. But we are all familiar with rooms, more especially in hotels, where everything that is said in one room can be overheard next door. This is generally ascribed to the thinness of the walls. Apart from absorption, which is not likely to be very appreciable in a homogeneous material, no large diminution of the intensity of the transmitted sound should be expected from a moderate increase in the thickness of the walls. The above example shows what may be expected from theory. When we deal with bricks and mortar, or lath and plaster, the want of homogeneity may cause a considerable amount of scattering, and this would help in making the increased thickness more effective.

Unless my information as to our present knowledge is insufficient, it would appear that experimental investigation of the acoustical properties of materials, with regard to absorption, scattering, and the rate of transmission, are much needed at the present time. Such investigations may also have a theoretical interest, as they would include experiments on sheets, the thickness of which bears a much smaller ratio to the wave-length than we are accustomed to deal with in optics.

ARTHUR SCHUSTER.

Some Spectrum Lines of Neutral Helium derived theoretically.

IT is well known that, owing to the prohibitive nature of the general problem of three (or more) bodies, Bohr's quantum theory has proved so far to be unable to account for any spectrum lines but those forming a series of the simple Balmerian type, *i.e.*

$$\nu=\kappa^2N\left(\frac{1}{n^2}-\frac{1}{m^2}\right),$$

where N is the familiar Rydberg constant given by $2\pi^2me^4/ch^3$, and κ the number of unit charges contained in the nucleus, or the atomic number. Apart from X-ray spectra of the higher atoms, for which κ is replaced empirically by a smaller and not necessarily a whole number (Moseley, Sommerfeld), and where the requirements of precision are not high, this simple type of formula covers, as a matter of fact, only the spectra of atomic hydrogen ($\kappa=1$) and of ionised helium ($\kappa=2$), which, having been deprived of one of its electrons, presents again the same problem of two bodies as the hydrogen atom. Accordingly, the known spectrum series of He^+, the ultraviolet Lyman series, the principal or Fowler's series, and the Pickering series, are all of the simple Balmer type, with $n=2, 3, 4$ respectively.

The neutral helium atom, however, with its two electrons, emits an entirely different spectrum consisting in all of more than a hundred lines (Prof. Fowler's latest report contains, pp. 93-94, a list of 105 lines), some apparently "stray" lines, others arrayed empirically into series strongly deviating from the Balmer type, but all alike baffling modern theoretical spectroscopists. In fact, not a single one of these one hundred or so observed lines has, to my knowledge, been accounted for theoretically, the mere desire of attempting this being paralysed by the insuperable difficulty of the three-bodies problem. This is particularly so in the case of lithium ($\kappa=3$) and the higher atoms.

Now, it has occurred to me that, in the absence of a general solution (in finite form, of course), it may be worth while to try some special solution of that classical problem.

At first a sub-case of Lagrange's famous solution of 1772 suggested itself, namely, the collinear type of motions, in which the three bodies, in our case

the nucleus and the two electrons, are always collinear with each other, the latter describing two equal and oppositely situated ellipses around the former. But the corresponding spectrum formula, which is again of the simple Balmer type, namely, $\nu=\frac{49N}{8}\left(\frac{1}{n^2}-\frac{1}{m^2}\right)$, proved to be entirely useless, as (to judge from one's numerous trials extended up to $n=8$) it does not cover, even within 1·5Å, a single observed line of He. This tends to show that such extremely special (collinear) states of motion, or at least passages between them, do not occur within the He-atoms, or if they do, then only so sporadically as to give no light of observable intensity.

What next suggested itself was the apparently trivial class of motions in which *the mutual perturbation of the two electrons is negligible*. Though approximate only, this class of solutions, being much broader than that of the collinear motions, would seem more likely to cover some actual spectrum lines. In fact, the very first trials gave encouraging results, as will be shown presently.

The energy of the system being for such states of motion equal to the sum of the energies due to the nucleus and each of the electrons taken separately, the corresponding spectrum formula for neutral helium is, obviously,

$$\nu=4N\left(\frac{1}{n_1^2}+\frac{1}{n_2^2}-\frac{1}{m_1^2}-\frac{1}{m_2^2}\right),$$

or $\nu=\nu_1+\nu_2$, where ν_1 and ν_2 are any two frequencies belonging to ionised helium, and thus represents a "combination principle" of a new kind. The resulting line of He, due to the passage of the two electrons from stationary orbits determined by m_1, m_2 to a pair of orbits determined by n_1, n_2, may conveniently be denoted by $\left(\frac{m_1 . m_2}{n_1 . n_2}\right)$.

This simple spectrum formula, the sum of two Balmerian ones, has yielded so far ten or eleven remarkably well-fitting lines, of which it will be enough to quote here a few.

Thus, to start with lines of the type $\left(\frac{m_1 . m_2}{4 . 4}\right)$, *i.e.* derivable from the Pickering series $\left(\frac{m}{4}\right)$ of He⁺, we have the frequencies (ν_1, ν_2)

$$\left(\frac{5}{4}\right) \quad . \quad . \quad 9875{\cdot}1,$$

$$\left(\frac{14}{4}\right) \quad . \quad . \quad . \quad 25191{\cdot}8,$$

the sum of which gives for the frequency of the theoretical line $\left(\frac{5 . 14}{4 . 4}\right)$

$$\nu=35067.$$

This agrees very closely with the nearest observed line at λ(air) 2851 or $\nu=35065$, which is tabulated among the combination lines of neutral helium (Fowler, p. 94). Similarly the members $\left(\frac{5}{4}\right)$ and $\left(\frac{20}{4}\right)$ of the Pickering series of He⁺ give $\left(\frac{5 . 20}{4 . 4}\right)$ with the frequency

$$\nu=9875{\cdot}1+26333{\cdot}6=36209,$$

which is in striking coincidence with the observed He-line at $\lambda=2761$ or $\nu=36208$.

In these examples both ν_1 and ν_2 are frequencies actually observed in He⁺. But not less interesting are lines of the type $\left(\frac{m_1 . m_2}{4 . 5}\right)$, *i.e.* combinations of Pickering lines with those of a purely theoretical He⁺ series $\nu=4N\left(\frac{1}{5^2}-\frac{1}{m^2}\right)$, and yet covering some observed lines of neutral helium very closely. Thus, we have (with $N=109723$):—

$$\left(\frac{6 . 9}{4 . 5}\right),\ \nu=27377,\ \lambda=3651{\cdot}8,$$

$$\left(\frac{6 . 17}{4 . 5}\right),\ \nu=31276,\ \lambda=3196{\cdot}4,$$

$$\left(\frac{6 . 19}{4 . 5}\right),\ \nu=31579,\ \lambda=3165{\cdot}7,$$

the nearest observed lines of neutral helium being λ3652·0, 3196·7, and 3166 respectively.

Finally, an example in which both of the combined frequencies are purely theoretical is

$$\left(\frac{6 . 28}{5 . 5}\right),\ \nu=22360,\ \lambda=4471{\cdot}00,$$

with the nearest observed He-line at $\lambda=4471{\cdot}48$, tabulated (*l c.*, p. 93) among the diffuse doublets.

Other examples of well-fitting lines and some further details are being given in a paper on this subject to appear in the September issue of the *Astrophysical Journal.*

Similarly one could try to cover some Li-lines by three pairs of terms, *i.e.* by $\nu=9N\left(\frac{1}{n_1^2}+\frac{1}{n_2^2}+\frac{1}{n_3^2}-\frac{1}{m_1^2}-\frac{1}{m_2^2}-\frac{1}{m_3^2}\right)$, and some spectrum lines of the higher atoms by four and more pairs of terms. But since, with increasing number of independent term-pairs, even a thorough agreement would appear more and more likely as the work of chance, it does not seem worth while to push the procedure much beyond lithium. For the latter element I have thus far found (with $N=109730$) eight well-fitting lines, of which the most interesting lines are $\left(\frac{5 . 14 . 18}{4 . 13 . 17}\right)$, $\nu=23394{\cdot}4$ and $\left(\frac{5 . 12 . 21}{4 . 10 . 18}\right)$, $\nu=26046{\cdot}6$, which are remarkably close to the lithium lines observed at $\nu=23394{\cdot}7$ and 26046·9. But by far more interesting seem, for the present at least, the coincidences obtained for neutral helium. These would seem to justify the conclusion that there is a good deal of independence between its electrons.

LUDWIK SILBERSTEIN.

July 18.

In my letter of July 18 I considered the formula:

$$\nu=4\mathrm{N}\left[\frac{1}{n_1^2}+\frac{1}{n_2^2}-\frac{1}{m_1^2}-\frac{1}{m_2^2}\right],$$

constructed as if the two electrons did not influence each other at all, and I mentioned that this spectrum formula had yielded ten or eleven well-fitting lines, of which six were actually quoted, the remaining lines being given in the full paper appearing in the *Astrophysical Journal.*

I now write to say that, to my own surprise, the same formula has since covered more than thirty further lines of neutral helium, and that when the whole ground is swept (by means of an auxiliary arithmetical table), almost the whole observed spectrum of helium is likely to be thus represented. While a complete list will be found in the paper referred to, some of these further lines may be quoted here so as to give an idea of the closeness of the agreement. Using the short symbol $\left(\frac{m_1 . m_2}{n_1 . n_2}\right)$ as already explained, we have, to five figures:—

Line.	$\nu_{calc.}$	$\nu_{obs.}$	Line.	$\nu_{calc.}$	$\nu_{obs.}$
$\binom{9 \;\; 24}{6 \cdot 7}$	14968	14970	$\binom{22 \cdot 24}{5 \cdot 7}$	24843·9	24843·96
$\binom{9 \;\; 15}{6 \;\; 6}$	17014·0	17014·3	$\binom{7 \cdot 19}{5 \cdot 5}$	24939	24935
$\binom{6 \;\; 10}{4 \;\; 7}$	19807	19805	$\binom{7 \;\; 21}{5 \;\; 5}$	25159	25157
$\binom{14 \;\; 14}{5 \;\; 8}$	19935	19932	$\binom{11 \;\; 22}{5 \;\; 6}$	25213	25215
$\binom{7 \;\; 11}{5 \cdot 5}$	22527	22529	$\binom{9 \;\; 18}{4 \;\; 8}$	25822	25820
$\binom{7 \;\; 18}{4 \;\; 8}$	23977	23980	$\binom{15 \cdot 15}{5 \;\; 6}$	25846	25849
$\binom{10 \;\; 20}{5 \;\; 6}$	24261	24260	$\binom{13 \cdot 20}{5 \;\; 6}$	26053	26047

The ν-region beyond 26047 has thus far not been swept systematically. When this is done, I have but little doubt that ninety or more of the one hundred and five lines of helium will be accounted for. In these circumstances one would feel justified in asserting that the absence of mutual repulsion between the electrons is not (as I first thought) an exception but rather the rule. A simple estimate will show that if the usual Coulomb repulsion law were valid in any of the considered stationary states, the mutual energy of the electrons would contribute several thousand units to ν. Since it is hard to explain away so many coincidences as due to chance, we are driven to the belief that the electrons within the atom do not repel each other even with a small fraction of the force usually attributed to them. In other words, the field of force of a bound electron seems to be entirely engaged by the nucleus, at least in the case of helium and probably of lithium, but possibly also in that of the higher atoms. The Primitive Crust of the Earth.

IN reference to the letter of Dr Harold Jeffreys (NATURE, July 29, 1922), I wish at once to say that nothing in my letter published on July 8 was intended to express my adhesion or non-adhesion to those who support the planetesimal hypothesis. Even if we think that the earth originated in a rain and concentration of solid planetesimals, we may, with Prof. R. A. Daly, regard its complete fusion at a later stage as a very probable event. At some time or other, the earth may well have possessed a crust consolidated from "igneous" fusion. Prof. J. Joly now suggests to us, with his unfailing brilliance of outlook, the recurrence of such a crust after successive meltings of the globe. What I have urged, however, is that the oldest rocks traceable by geologists must not be regarded as a record of a primitive crust. They are sediments, invaded again and again by igneous matter from below. We cannot conclude from our Archæan schists, which are so often converted into composite gneiss, that there was ever a crust formed of crystalline rocks about the globe. The "extent of the crust accessible to geologists" is, of course, much more than the film 2·5 km. thick stated by Dr. Harold Jeffreys. Owing to the great movements that bring up antique masses from the depths, rocks that consolidated finally under several miles of sediments now form a large part of the surface. But so far no planetesimal sediment has come to light, although matter of the mineral composition demanded by the hypothesis is associated with many igneous upwellings.

In support of the concluding remarks of Dr. Harold Jeffreys, attention may be directed to "A Critical Review of Chamberlin's Groundwork for the Study of Megadiastrophism," by W. F. Jones, published in the *American Journal of Science* for June of the present year. GRENVILLE A. J. COLE.

Peculiarities of the Electric Discharge in Oxygen.

SEVERAL years ago I described (*Phil. Mag.*, April 1908) a discontinuity in the electric discharge in oxygen at pressures near to 0·8 mm. Namely, when a current (0·0025 amp.) was passed in a discharge tube (diam. 2·4 cm.), the electric force in the positive column suddenly changed on slightly lowering the pressure from about 11 volts per cm. to about 20, an effect which could be reversed by raising the pressure.

Some experiments which I have made recently, with the assistance of Mr. E. P. Cardew, have shown that at pressures in the same neighbourhood, with a fixed circuit (battery and resistance), the discharge is not uniquely determined, but can be one or the other of two distinct types, distinguished by a remarkable difference in the values of the electric force within the positive column, one of these values being about twice the other. The magnitude of the current with the higher electric force in its positive column is less than the other, since the potential difference of the electrodes is greater in its case; but the currents tend to equality when the electrodes are so near that the positive column tends to disappear. The two discharges differ only slightly in appearance: the positive column of the smaller one with the higher electric force being somewhat shorter and a trifle paler than the other—both being without striæ in general.

To give an example. With a battery of 990 volts and external resistance 363,000 ohms, electrodes 21·8 cm. apart in a tube of 27 mm. diameter, and pressure 0·75 mm., the currents observed were 1·19 and 0·883 milliamperes; their positive columns were nearly 15 and 14 cm. long, and the electric force within them about 9 and 18·5 volts per cm. respectively. In this and in many other cases, by means of a certain arrangement, the discharge could be made to change from one form to the other without stopping the current or altering the circuit.

The region of pressures within which alternative currents have been so far observed are from 0·64 to 0·91 mm. The two types of discharge differ in stability according to the pressure and the magnitude of the currents, so that the discharge tends to assume one type rather than the other. But the one having the high electric force in the positive column is much more definite and invariable than the other for a given pressure, being in this respect similar to discharges in other gases, so that that electric force can be determined with much more precision, and is in fact nearly the same as in hydrogen.

Since these effects hold good for a large range of current, it is obviously possible, by adjusting the external circuit, to make two discharges of the same arbitrary magnitude (of the necessary order) pass through oxygen, between electrodes at a given distance apart, at any given pressure within the range in question, one of which will have the high electric force in its positive column and the other the low. Defoliation of Oaks.

A REFERENCE to the defoliation of oaks, particularly on the borders of Surrey and Hampshire, by the larvæ of *Tortrix viridana*, was made in NATURE on June 10. It concludes with the remark that the effect of the defoliation is to check "the growth of the trees to some extent for the time being, but is rarely more serious"

At Haslemere, in the south-west corner of Surrey, infestation by the Tortrix larvæ was sufficiently marked fifteen years ago to be the subject of comment, and it has continued ever since. In some years the attacks were very severe For a long time infested trees did not appear to suffer any serious harm. In recent years, however, the American White Mildew, *Oidium alphitoides*—which in the early years of its appearance in this country infested the leaves of pollard and sapling oaks only—has invaded the new leaves which the trees put forth after defoliation by the caterpillars The effect of the combined attack is already becoming very serious In the tract of country lying between the towns of Haslemere, Petersfield, Midhurst, Petworth, Horsham, and Godalming, many oaks have been killed outright, and large numbers are slowly dying It seems very desirable that these dead and dying trees be removed and destroyed, or they may become centres for the spread of beetles destructive to timber.

Scorpions and their Venom.

PHYSALIA in "Animaux Venimeux," p 252, says that in all venomous animals their immunity to their own venom is limited, and announces that in an experiment a scorpion, *Butheus australis*, was killed by an injection of the same venom as its own I should like to add further observations from personal experience, bearing on this very interesting subject

Until very recently, by many, and even now by some, the accepted opinion of men of science was that each venomous animal carried its own antidote, *i e* was immune to the effects of its own venom

So long ago as 1900, when for some weeks during the Boer War I was stationed with my company in the Blue River mountains opposite the Metrosberg Peak in Cape Colony, I witnessed numerous fights between the different species of scorpions In more than a hundred fights between two scorpions, each of the same species, whether black, red or yellow, the result was always the same, the one that was stung by its opponent dying almost immediately, 10 seconds being the longest interval between receiving the sting and death.

The result when *different* species were pitted against each other was the same, but that was to be expected

Bloomsbury.

IT is to be regretted that in his interesting article on Bloomsbury and the University of London, Mr. Humberstone repeats the erroneous statement that Bloomsbury was originally Lomesbury That statement was made by John Stow, London's first historian, but one can only suppose that he was misled by the mistake of some early copyist. The earliest form of the name known to me is Blemundesberie. I am writing away from references, but that form is at least as old as the fourteenth century. Like other place-names ending in -*sbury* it must be derived from the personal name of its owner, possibly Blemund.

The further statement that the Royal Mews, at Bloomsbury, were burnt down in 1537, is also not quite accurate. The royal stables were burnt then, but the Mews (*i e.* falconry) were situate at Charing Cross, on the site of the present Trafalgar Square, at least as early as 1443 (the earliest reference verifiable at the moment) It was the transference of the royal stables to Charing Cross that led to the change in the meaning of the word "mews" to that which it still bears.

A. MORLEY DAVIES.

Amersham, July 29.

I REGRET that my article should have contained the errors to which Dr. Morley Davies draws attention. Stow wrote "But in the yeare of Christ 1534. the 26. of H the 8. the king hauing faire stabling at Lomsbery (a Manor in the farthest west part of Oldborne) the same was fiered and burnt, with many great horses, and great store of Hay. After which time, the forenamed house called the Mewse by Charing Cross was new builded, and prepared for the stabling of the kings horses. . . " H B Wheatley in "London Past and Present" states that Bloomsbury is a corruption of Blemundsbury, the manor of the De Blemontes, Blemunds, or Blemmots. Blemund's Dyche, which was afterwards Bloomsbury Great Ditch, and Southampton Sewer divided the two manors of St Giles and Bloomsbury. He adds: "There is an absurd statement, taken from Stow's Survey, that the name of Bloomsbury was originally Lomsbery This could only have occurred by a misprint, in which the B was inadvertently dropped."

T LL HUMBERSTONE.

Absorption of Potassium Vapour in the Associated Series.

IN our investigations on the optical properties of potassium vapour we found that there were some traces of absorption in the above series at about 1100° C, the results of which were embodied in a note to appear shortly in the *Phil Mag* As a result of further experiments conducted in the Physical Laboratory of this college, we now feel fairly sure that we have detected distinct traces of absorption in the diffuse series; the bands 5780, 5340, 5300, and 5100 surely correspond to 5782, 5340, 5323, and 5100 of $(2p-md)$

The well-defined dark line 4640 previously observed by us at about 900° C. is confirmed to be the combination line $(1s-2d)$ recently observed by Datta in the vacuum arc spectrum of potassium (Proc. Roy. Soc, 99, April 1921) and by J. K Robertson on "Electrodeless Discharge in certain Vapours" (*Physical Review*, May 1922).

At these high temperatures the chemical difficulties are so great, and the conditions in the experimental tube so unstable, that, in spite of many attempts, we found it difficult to obtain a good negative, on account of the tube giving way owing to the chemical action of potassium vapour on its walls. Further experiments are in progress, and we hope to confirm these observations by photography, as these experiments lend weight to Saha's theory of temperature radiation.

A Recording and Integrating Gas Calorimeter.

By Dr. J. S. G. THOMAS, Senior Physicist, South Metropolitan Gas Company.

UNDERTAKINGS operating under the provisions of the Gas Regulation Act 1920, are required to deliver gas of a declared calorific value to consumers, and charges to individual consumers are to be based upon the value of the total thermal energy supplied to each. By calorific value is to be understood the number of B.Th.U. produced by the combustion of 1 cubic foot of gas measured at 60° F. under a pressure of 30 inches of mercury and saturated with water vapour. Under the Act, penalties are to be inflicted upon the gas undertaking, if on any day for a period of two hours or more the calorific value of the gas supplied is more than 6 per cent. below the declared calorific value, or if in any quarter the average calorific value is less than the declared calorific value. Embodied in Orders under the Act are clauses governing the price per therm (100,000 B.Th.U.) to be charged by individual gas undertakings, and the amount of dividend to be paid to proprietors, as regulated by this price. Such, in brief, are the main thermal clauses of the Gas Regulation Act 1920—the Charter of Liberty of the gas industry in this country, and the consumers' guarantee that gas undertakings must and will "deliver the goods."

Accurate gas calorimetry has long been of importance for scientific purposes; *extremely* accurate gas calorimetry is now of consequence industrially and socially. The accuracy of determination desirable will be realised when it is understood that, in terms of money, an error of 1 per cent. in respect of the thermal value of the annual gas supply of England, Scotland, and Wales represents about 500,000*l*.

Prof. C. V. Boys, at the annual meeting of the Institution of Gas Engineers on June 22, exhibited and described a recording and integrating calorimeter (Fig. 1) which he has designed and constructed primarily to meet the requirements of the Act in the matter of continuously recording the calorific value of towns' gas. The instrument is, however, immediately applicable to the determination and recording of the calorific value and percentage variation with time of the calorific value of *any* gas. It is of the water-flow type, the same water being circulated continuously through the apparatus and cooled to atmospheric temperature, by the hot-air engine and cooling coil seen at the bottom left-hand side of the figure. This is an important consideration in continuous calorimetry, as with another form of recording gas calorimeter at present available the cost of water amounts to about 20*l*. per annum. The fundamental features of the instrument are: water and gas are doled out positively at the correct respective rates, and the correction for gas volume as affected by temperature, pressure, and humidity are likewise effected by a positive operation.

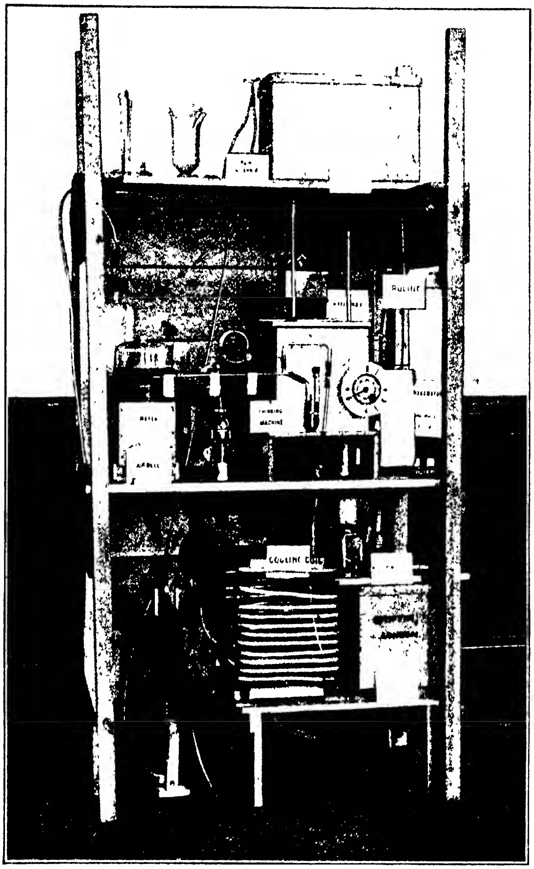

FIG. 1.

Water Measurement and General.—Water flows from a tank, seen in the top right-hand corner of Fig. 1, where the level is maintained constant, through a nozzle into a celluloid bucket pivotted eccentrically and so proportioned that it overbalances and empties into the celluloid water-box shown in Fig. 1. After emptying and draining, the bucket is released by a clock every half-minute, and the operation is repeated. The quantity of water delivered to the bucket can be adjusted by a stop, so that if the gas is of the declared calorific value, the rise of temperature of the water flowing in the calorimeter is exactly 10° C. On the record sheet, therefore, corresponding percentage

departures from the declared calorific value are strictly comparable, being represented by equal displacements of the recording point, whatever the declared calorific value.

The water doled out passes through a small hole into a second compartment of the water-box, and thence to the calorimeter proper. When the bucket is overturned, the jet of water misses the bucket and enters a third compartment of the water-box, whence it passes to a fourth compartment, to be delivered to a small celluloid water-wheel, which drives, through an elastic connection, the escapement of a one-wheel pendulum clock ticking half-seconds, and through an intervening mechanism - called by Prof. Boys the "thinking machine"—the axle of the gas meter.

The Gas Meter.—The gas meter is shown in vertical section in Fig. 2, the smallest arrow indicating the direction of entry of gas previously saturated with water vapour. The meter drum is of celluloid, and is provided with buoyancy chambers A, so that the drum is largely carried by the water and not by the axle. The gas measured in any compartment is therefore contained

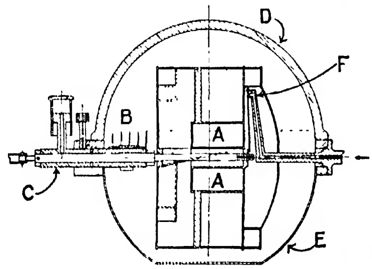

FIG. 2.

in a chamber of which the sides, ends, roof, and about two-thirds of the floor are independent of the water-level, which can be adjusted to $\frac{1}{10000}$th inch by reference to the upturned points, B. Changes of water-level, even if they should occur, would clearly have little effect on the capacity of the meter. The meter drum rests loosely on the axle, which is screwed, so that if meter and axle turn at the same rate there is no endlong movement of the drum. The axle works in a long sleeve, C, screwed into a brass ring, and vaseline is forced in to make axle and sleeve water-tight. No stuffing boxes are employed, and the inlet and outlet aprons of the usual wet-meter drum are replaced by discs closing the front and back of the usual four compartments. The meter is enclosed gas-tight within a glass bell D above, and a spun copper bowl, E, below. The pressure in the meter is about $\frac{1}{8}$ inch of water in excess of atmospheric, such excess being due to the inclusion in the gas circuit of a pin-hole burner to prevent the calorimeter burner being extinguished by the sudden slamming to of a door, etc.

The "Thinking Machine."—This device, already referred to, is shown in plan in Fig. 3A. It consists of a small ball-disc-cylinder integrator, a vertical section of which is shown in Fig. 3B, coupled with epicyclic double reduction gear, as shown at A in Fig. 3A, inserted between the clock and the meter axle so as to control the rate of revolution of the meter drum. The epicyclic device gears down the motion of the disc of the integrator in the ratio 3 : 2, the disc itself being geared down from the water-wheel in the ratio 4 : 1. The motion of the cylinder of the integrator is geared down in the ratio 15 : 1.

Temperature and pressure corrections to the gas volume are automatically and positively effected in the following way. It is clear that if the ball, B (Fig. 3B), makes contact with the rotating disc, C,

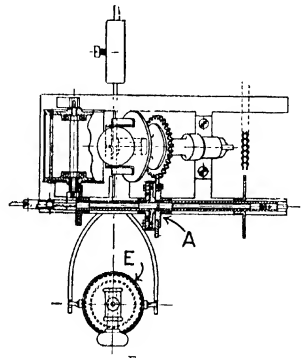

FIG. 3A.

exactly at the centre of the disc, no rotary motion will be communicated by the disc to the ball and consequently none to the cylinder D. Such a position of the ball corresponds to normal conditions of temperature (60° F.) and pressure (30 ins. of mercury) of the gas, and may be conveniently referred to as its N.T.P. position. The radial displacement of the ball from the centre of the disc is made to depend upon atmospheric temperature and pressure as follows: E (Fig. 3A) shows in plan a glass bell filled with air floating

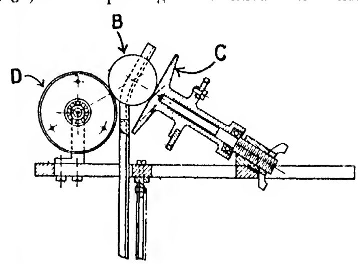

FIG. 3B.

in a mercury and water seal, and connected by a lever system with a fork which displaces the ball to one side or other of the centre of the disc, according as the bell rises or falls with change of atmospheric conditions. The lever system is such that the ball moves 1 inch, equal to the radius of the cylinder, when the gas volume correction is 10 per cent. Such displacement of the ball is accompanied by its rotation, producing rotation of the cylinder, D, whereby endlong motion is communicated to the meter drum, resulting in the gas inlet to the meter, F, Fig. 2, being further closed or opened as required, so that the rate of gas delivery

reduced to standard conditions is maintained constant to within $\frac{1}{10}$ per cent. The corrections effected over a period of a month are automatically recorded on a drum revolving above the device. The method of mounting the meter drum loose on a screwed axle also prevents the occurrence of accidents should the gas supply be temporarily cut off and resumed later, or should the water flow cease. The possible interference of a mouse with the righting of the bucket after emptying is also ingeniously provided for.

The Calorimeter Proper.—This is shown in vertical section in Fig. 4. A and B are the hot and cold water chambers respectively; C is the heat interchanger, in which the heat of the products of combustion derived from gas burning at the fused-silica burner, D, is communicated to the stream of water. A silica dome is disposed above the flame. The interchanger is made of sheet-lead closely folded into fifteen zig-zags round the central combustion space. Narrow up-cast water-ways are then formed on one side of the sheet, and down-cast gas-ways on the other side. The heated water passes to B through the narrow neck in the double partition, E, a device introduced by Prof. Boys to prevent the calorimeter indicating more heat than is produced by the gas. The copper cylinder, F, fixed to the brass ring, G, is so proportioned, that loss of heat from the upper part of the hot-water compartment is compensated by the equal gain from the cylinder lower down by the heat interchanger.

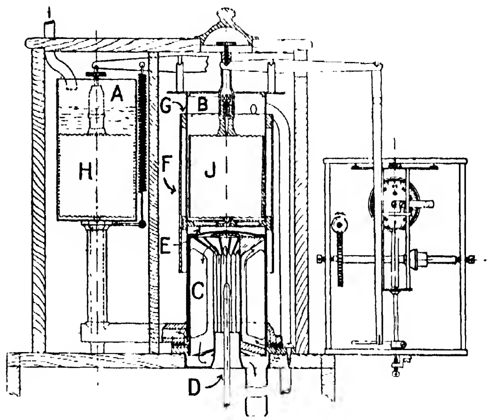

FIG. 4.

The operative thermometers, H and J, are of brass, and are filled with amyl alcohol. They are closed with corrugated brass covers. A lever system utilising the third dimension of space, magnifies the deformation of the respective covers occurring with change of temperature, and the net difference of temperature of the two thermometers, due to heating, controls the position of an inked pen recording on a roll of paper seen on the right of Fig. 1, kept in motion by the clock. On the paper parallel lines are ruled during the rotation, indicating definite percentage departures of the actual measured calorific value of the gas from the declared calorific value. Time indications are in like manner impressed upon the record. An integrating device shown on the right of Fig. 4, operating after the manner of the Amsler planimeter and controlled by the position of the recording pen, averages the departures of the calorific value of the gas from the declared calorific value since the indicator was last set to zero, *i.e.*, since the beginning of the quarter, so that, for example, the integrator indicating +5 would signify a 5-day 1 per cent. excess of calorific value, or a 1 day 5 per cent. excess, etc.

The writer is extremely obliged to Prof. Boys for the kind manner in which he has afforded information concerning the instrument, and to Messrs. Griffin and Sons for providing the illustrations reproduced in this article.

The Earth's "Crust" and its Composition.

By THOMAS CROOK.

THE term "crust" is frequently used in dealing with the constitution of the earth, but is seldom defined. It is a convenient scientific term to apply to the earth's outermost shell, the only portion of which geologists have much positive knowledge, and if it is put to scientific use, it should be defined, although a definition of it may involve some hypothesis as to the physical condition of the earth's interior.

According to Arrhenius, who assumes that the temperature-gradient observed in continental areas is persistent in depth, the temperature of the earth's interior greatly exceeds that of the critical temperature of the materials occurring there. He infers therefore that the interior is for the most part gaseous though rigid, and that this gaseous core is separated by a molten layer from an outer solid shell about 40 miles thick. Osmond Fisher assumed a molten condition at a depth of 25 miles. To those who accept this view, the term "crust" has a very real and simple significance: it is the thin, solid, outer shell of the earth, underlain by molten magma.

At the present time, however, this hypothesis appears not to be widely held among geophysicists, most of whom follow Lord Kelvin, Sir George Darwin, and other eminent authorities who have shown good reasons for rejecting the hypothesis of a molten interior at such depths as postulated by Fisher and Arrhenius, and who claim that the earth is solid throughout. For those who adopt this view the definition of the earth's "crust" is a more difficult matter.

The prevalent view at the present day as regards the constitution of the earth's interior is that it consists of an inner core of nickel-iron about 6200 miles in

diameter, surrounding which is a silicate shell some 900 miles in thickness. The silicate shell is largely ultra-basic and basic. Lying on the thick shell of basaltic rock, which girdles the whole earth, is a comparatively thin and discontinuous layer of more siliceous rock-matter (granite and gneiss), on which the sedimentary rocks have been formed in and around the continental areas. According to the conception of a solid earth so constituted, we clearly have no satisfactory basis for defining the earth's "crust" in terms of the kind of rock of which it is made up, and unless it can be shown that, at some convenient and fairly uniform depth, the rock-substance of the earth undergoes a critical change in its physical condition at the temperature and pressure prevailing there, the only available alternative is to define the "crust" in a more arbitrary manner in terms of depth.

One way of doing this is to limit its thickness, as some authors do, to that outer portion of the earth of which we may be said to have observational knowledge. The maximum depth at which rocks observable at the surface of the earth have been formed is quite an important geological problem from the economic as well as from the scientific viewpoint, and one that appears never to have been treated adequately. It may, however, perhaps safely be inferred that, by observation of surface geological features, we have a knowledge of the earth down to a depth of more than 5 miles, but considerably less than 10 miles.

In their most recent estimate of the average composition of the earth's "crust," Drs. F. W. Clarke and H. S. Washington, of the United States Geological Survey, give its average composition down to depths of 10 and 20 miles. The detailed statement of their results has not yet been published, but is to be issued as a Professional Paper by the U.S. Geological Survey. Pending the publication of the detailed report, however, they have given a brief account of their results in the Proceedings of the National Academy of Science (1922, vol. 8, p. 108).

The method adopted by them for ascertaining the average composition of the lithosphere is to take the average of trustworthy analyses of igneous rock specimens collected from various parts of the earth's surface. They have included 5159 analyses. Averages are given separately for the igneous rocks of the United States; North America other than the United States, including Greenland; Central and South America; Europe; Africa and Asia; Australasia, Polynesia and Antarctica. In computing the averages for these various regions the sum total of each constituent was divided by the total number of analyses of specimens from the region dealt with. In calculating the composition of the earth's "crust" as a whole, the proportions of the lithosphere, hydrosphere and atmosphere for a depth of ten miles were taken as follows:—lithosphere 93 per cent., hydrosphere 7 per cent., and atmosphere 0·03 per cent. The lithosphere is assumed to be made up as follows:—igneous rocks, 95 per cent.; shale, 4 per cent.; sandstone, 0·75 per cent.; and limestone, 0·25 per cent. Figures are given for the rarer as well as for the commoner elements.

The following is the result obtained for the average chemical composition of the igneous rocks of the earth:—

AVERAGE IGNEOUS ROCK.

	Per cent.		Per cent.
SiO_2	59·12	F	0·030
Al_2O_3	15·34	S	0·052
Fe_2O_3	3·08	$(Ce, Y)_2O_3$	0·020
FeO	3·80	Cr_2O_3	0·055
MgO	3·49	V_2O_3	0·026
CaO	5·08	MnO	0·124
Na_2O	3·84	NiO	0·025
K_2O	3·13	BaO	0·055
H_2O+	1·15	SrO	0·022
CO_2	0·101	Li_2O	0·008
TiO_2	1·050	Cu	0·010
ZrO_2	0·039	Zn	0·004
P_2O_5	0·299	Pb	0·002
Cl	0·048		
			100·000

The following table shows the estimated percentages of the commoner elements in the lithosphere, hydrosphere and atmosphere:—

ELEMENTS IN THE LITHOSPHERE, HYDROSPHERE, AND ATMOSPHERE.

	1	2	3	4
Oxygen	49·19	47·80	46·68	46·41
Silicon	25·71	26·65	27·60	27·58

1 Average composition. Ten-mile crust, hydrosphere, and atmosphere.
2 Average composition. Twenty-mile crust, hydrosphere, atmosphere.
3. Average composition. Ten-mile crust, igneous and sedimentary rocks.
4 Average composition. Ten-mile crust. Igneous rocks.

A serious defect in the method of procedure on which the above estimates by Clarke and Washington are based is that it makes no allowance for the relative magnitude of the different kinds of rock of which the lithosphere is composed. They admit this defect, but claim that any errors involved are likely to be compensating (*Journ. Franklin Inst.*, 1920, vol. 190, p. 770). Their claim can scarcely be allowed, however, even for the outer 10 miles of the "crust," and still less can it be allowed down to a depth of 20 miles.

As to the relative proportions of the rocks composing

the lithosphere at this depth, even at 10 miles, we have as yet no positive knowledge, but the distribution of igneous rocks at the surface of the earth, and a comparison of oceanic and continental regions, give us some important facts to guide our reasoning on this matter. We are probably not far from the truth if we assume that the granitic portion of the lithosphere is largely restricted to the continental regions of the earth, and its thickness may not exceed an average of about 5 miles. If so, assuming this granite layer in continental regions to contain on an average 70 per cent. of silica, and assuming that it is underlain to a depth of 10 miles from the surface by basalt containing on an average 48 per cent. of silica, this would give us a silica percentage of about 59 for the average igneous rock of the lithosphere in continental regions down to a depth of 10 miles, which is in agreement with the average of the igneous rock of the "crust" as estimated by Clarke and Washington.

It should be noted that this takes no account of the "crust" of the oceanic regions, which is probably in large part basaltic. We may for the purpose of this argument assume that the granite shell of continental regions covers half the earth. This is an extravagant assumption, but as it doubtless errs substantially in exaggerating the acidity of the "crust," the error is on the right side so far as the present argument is concerned. If we further assume the sub-oceanic "crust" down to a depth of 10 miles to be basaltic, and to contain on an average 48 per cent. of silica, this would give us an average igneous rock containing about 53½ per cent. of silica for the outer 10 miles of the lithosphere all round the earth.

Extending our considerations to a depth of 20 miles, there can be little doubt that we should regard the deeper 10 miles as on the whole more basic than the basaltic material of the outer 10 miles, and it is reasonable to assume that this deeper layer of basalt does not contain on the average more than 46 per cent. of silica. If we make this assumption, then the average rock of the earth's "crust" as a whole down to a depth of 20 miles would contain not more than about 50 per cent. of silica.

Comparing these with the figures given above by Clarke and Washington, the inference we draw is that they have probably much understated the basicity of the earth's "crust." Their average down to a depth of 10 miles is, as we have seen, only acceptable for continental regions, and cannot be admitted for the earth as a whole. Still less can their average for the lithosphere down to a depth of 20 miles be admitted, for, as we have seen, there is good reason for believing that the average rock down to this depth probably corresponds to a gabbro, containing about 50 per cent. of silica, rather than, as they infer, to a granodiorite containing 59 per cent. of silica.

This question of the average composition of the earth's "crust" has important bearings on many scientific and economic problems. It is quite commonly assumed that the average igneous rock is intermediate in composition, and that granitic and basaltic eruptives are products of differentiation derived from intermediate magmas. It seems highly probable, however, that the average igneous rock of the earth's crust is basic; and although differentiation does undoubtedly play an important part in the formation of igneous rocks, the claim that granites and basalts are in general differentiates from magmas of intermediate composition has no adequate foundation in the facts known to us concerning the petrology of the earth.

Centenary of the Death of William Herschel.

On August 25, 1822—a hundred years ago—William Herschel died at Slough, aged eighty-three years and nine months. His scientific activity had continued almost to the end of his long life. His last published paper was read before the Royal Astronomical Society (of which he was the first President) in June 1821. It is the only one of his seventy memoirs which was not published in the Philosophical Transactions, of the yearly volumes of which for the years 1780 to 1818 inclusive only those for 1813 and 1816 contain nothing by him, while not a few volumes include several papers from his hand. Even in the last year of his life, when his son, under his continual guidance, made and figured the 18¾-inch mirror, which was afterwards used by Sir John Herschel at Slough and at the Cape, it is recorded that "the interest he took in this work and the clearness and precision of his directions showed a mind unbroken by age and still capable of turning all the resources of former experience to the best account."

When Herschel, on March 1, 1774, began to keep a record of what he saw in the heavens with telescopes made by himself, it was natural that he should for some years show no decided preference for any particular branch of astronomy. At first he paid some attention to the planets, and determined the rotation-periods of Jupiter and Mars. But it did not escape his clear perception very long that what was urgently required at that time was a systematic study of the vast number of celestial bodies outside the solar system. If Herschel had not early grasped this fact, and persevered all the rest of his life in his devotion to sidereal astronomy, he would never have become a great astronomer, but would merely, like his contemporary, Schroter, have been known as an indefatigable observer who occasionally did some good work. But on his way from the solar system out into space beyond it Herschel found a new planet (Uranus), about twice as far from the sun as what had up to then been considered the outermost planet. This was not a lucky accident, but a discovery which was bound to be made sooner or later by an observer who searched the heavens as systematically as he did. It was the first time since the prehistoric ages that a new planet was discovered. Herschel afterwards found two satellites of Uranus and two of Saturn, but his principal work was always on subjects connected with sidereal astronomy.

"A knowledge of the construction of the heavens has always been the ultimate object of my observations." This was the opening sentence of his paper of 1811, and as he had said much the same in the concluding words of his first paper (of 1784) on that subject, we see how faithful he remained to the plan of work he had adopted early in his scientific career.

Speculations on the construction of the universe had been made before Herschel's time: by Thomas Wright in 1750, by an anonymous writer in 1755 (who afterwards turned out to be Immanuel Kant, and adopted most of Wright's conclusions), by Lambert, and by Michell. None of these writers had made any observations on which to found their theories. But Herschel would build on observed facts so far as possible. He began by attempting to find the distance of the fixed stars by measuring double stars. This turned out to be impossible; but the work done was not wasted, as hundreds of double stars had been found and measured. When many of these measures were repeated some twenty years later, the great discovery was made that not a few of these pairs of stars were revolving round their common centre of gravity. The nebulæ and clusters of stars were next systematically searched for; 2500 were found and their places determined. Herschel started with the idea that all nebulæ were composed of stars, and he therefore included clusters, even rather scattered ones, in his observations, as representing with dense clusters and nebulæ the different stages of the same class of bodies. But the discovery of some indubitably nebulous stars, or stars with atmospheres, made him recognise that there must be here and there in space some kind of "shining fluid" of which diffused nebulæ and planetary nebulæ were formed. This idea found very little favour among astronomers for many years, particularly after the completion of Lord Rosse's 6-foot reflector, the maker of which was inclined to think every nebula "resolvable" Yet Herschel was found to be right when Huggins proved many nebulæ to have a gaseous spectrum.

Another discovery of Herschel's, which was doubted or denied until confirmed elsewhere, was the proper motion of the sun through space. Here there was perhaps some excuse for the doubters, as the material available for the investigation was rather scanty.

In order to get some idea of the distribution of the stars Herschel for some years took observations of the star-density in various parts of the sky by counting the stars seen in the field of his telescope. Making two assumptions—that his telescope could reach the boundaries of the Milky Way, and that the stars of the system were tolerably uniformly distributed—he was able to construct a rough diagram of the shape of the Milky Way system to which our sun belongs. This is the well-known disc or grindstone theory, according to which the stars are scattered between two planes, roughly parallel to the belt of the visible Milky Way, with a stratum running out to one side to represent the bifurcation from Cygnus to Scorpio. Near the centre of this system (also spoken of as "our nebula") Herschel placed our sun. In after years, in two papers of 1817 and 1818, Herschel, as a result of his observations, was obliged to abandon the idea of uniform distribution, and also to recognise that his telescope could not reach the boundaries of the Milky Way system But that the system extended very much further in the plane of the Milky Way than at right angles to it, remained his opinion, though the conception of the system being a nebula—that is, a star cluster—had been given up.

Here again there was, towards the end of the nineteenth century, a tendency to abandon Herschel's results, and the opinion was set forth in more than one quarter, that the Milky Way is really what it looks like—a huge ring-shaped cluster. It has even been suggested that it is a gigantic spiral nebula inside which our sun is situated - at first sight a rather tempting proposal. But recent researches by Shapley have shown these hypotheses to be untenable, and his work on the distribution of globular clusters, showing the enormous distances of many thousands of light-years which separate them from us, agrees in a remarkable manner with the ideas worked out by the old astronomer at Slough exactly a hundred years earlier, in the last paper he sent to the Royal Society. J. L. E. D.

Obituary.

Dr Arthur Ransome, F.R.S.

The death of Dr. Ransome at Bournemouth in his eighty-ninth year recalls the memory of a Manchester physician who was a pioneer in the training of female health visitors, and in the investigation of tuberculosis and of the cyclical waves of epidemic diseases. He died on July 25, and by a striking coincidence, at the first meeting earlier in the same day of Section I.—that of Preventive Medicine—of the Congress of the Royal Sanitary Institute then being held in Bournemouth, a message of appreciation of Dr Ransome's past work had been authorised, which never reached him.

Dr. Ransome was born in Manchester in 1834. He became an honorary fellow of Gonville and Caius College, Cambridge, and for many years was consulting physician of the Manchester Hospital for Consumption, as well as Professor of Hygiene and Public Health at Owen's College, 1880–95.

Dr. Ransome's chief writings related to tuberculosis, on which he published several books as well as special contributions to the Epidemiological and other Societies. He gave the Milroy lectures to the Royal College of Physicians on the causes of phthisis, and received the Parkes Weber prize for special researches on tuberculosis. From his experiments he concluded that finely divided tuberculous matter is rapidly deprived of virulence in daylight and in free currents of air; that even in the dark, fresh air has some, though a retarded disinfecting influence, and that in the absence of currents of air the tubercle bacillus retains its infectivity for long periods of time. The general effect of his work was to emphasise the importance of disinfection of rooms occupied by tuberculous patients. At the same time Dr. Ransome attached greater importance to sanitary and social improvements in the prevention of tuberculosis than to direct attack on the bacillus.

In epidemiology Dr. Ransome was one of the first to investigate the influence of cyclical waves in producing the intermittent prevalence of epidemic diseases, apparently independent of the accumulation of unprotected persons. The Swedish tables of mortality,

of unique historical duration, furnished him, as they did other investigators, with the data for the construction of charts, which showed, for example in scarlet fever, not only a short cycle for that country of four to six years, but also a long undulation of from fifteen to twenty years or more, which, as he said, might "be likened to a vast wave of disease upon which the lesser epidemics show like ripples upon the surface of an ocean swell" (Epidemiological Society's Transactions, 1881-82).

Dr. Ransome wrote much also on general public health subjects, always with a keen appreciation of the value of vital statistics and of the pitfalls to be avoided. Thus, in any population, except that of a life-table, in which births equal deaths and migration is absent, a death-rate of 10 per 1000 does not mean an average duration of life of 100 years. As he put it: "under present conditions such figures . . . can only be looked for in the millennium, when, as Isaiah says, the child shall die an hundred years old."

Dr. Ransome taught at an early date that "preventible" mortality extended far beyond epidemic diseases; and was singularly accurate in his forecast that infant mortality, which "had not yet received full attention from the sanitary administrators of the country," would hereafter prove largely controllable.

In a paper contributed to the *Lancet*, July 11, 1896, Dr. Ransome drew a striking comparison between leprosy and tuberculosis, arguing that in view of the close analogy between the two diseases there is reason to hope for a diminution of tuberculosis as striking as that already experienced in leprosy. The subject is too large to be expanded in this column, but this paper deserves to be consulted.

The above illustrations of some portions of Dr. Ransome's life-work show how wide were his studies and how prescient his teaching. A special shelf will always be reserved for his writings by students of tuberculosis and of general epidemiology. Many years ago Dr. Ransome retired to Bournemouth, where, until a few weeks before his death,—when the present writer received a letter from him on an epidemiological point,—he maintained his interest in his life-studies.

PROF. GISBERT KAPP.

BY the death on August 10 of Prof. Gisbert Kapp, the country loses one of the few remaining pioneers of electrical engineering. Prof. Kapp was born at Mauer near Vienna in 1852, his father being German and his mother Scottish. At the Zurich Polytechnic he was a pupil of Zeuner and Kohlrausch. In 1875 he came to England, but spent several years afterwards in travelling on the Continent and in North Africa. He was appointed engineer to the Chelmsford Works of Messrs. Crompton and Co. in 1882, and in conjunction with Mr. (now Colonel) Crompton he invented a system of compound winding for dynamos. At this period England was the leading country in the world in electrical engineering. In 1886—the year in which John and Edward Hopkinson published their classical paper on dynamo design—Kapp read a paper on a similar subject to the Institution of Electrical Engineers. He pointed out clearly the analogy between the magnetic circuit of a dynamo and an ordinary electric circuit. In this year also he published his book on the transmission of electrical energy which gave a very clear introduction to the whole problem. In the autumn of 1894 he accepted the post of secretary to the German Association of Electrical Engineers. He was also a lecturer to the Technical School at Charlottenburg and was editor of the *Elektrotechnische Zeitschrift*. In 1904 he was appointed the first professor of electrical engineering to Birmingham University.

As an inventor Kapp was in the front rank. The Kapp dynamos were very useful in their day. The Oerlikon Company, of Switzerland, built many large Kapp machines. But like all the other early types they are now superseded by machines with revolving fields and armature windings embedded in slots. Kapp also invented many types of measuring instruments, a method of making dynamos self-regulating, several types of transformer, a high-speed steam-engine, a system of distributing alternating currents, and a method of boosting the return feeders on electric railways. This last method has still considerable vogue in this country and in Germany.

Kapp was an excellent teacher. Many of the present-day electricians acquired their first ideas of the working of electric machinery from his books. His mathematical theorems were original and in several cases strikingly simple—for example, his formulæ for the free period of coupled alternators. He invented many laboratory methods of testing machines. His test for the efficiency of dynamos and his method of getting the moment of inertia of the rotor of a machine are particularly valuable. He also invented a method of getting the insulation resistance of a three-wire network without the necessity of shutting down the supply. He was one of the earliest to recognise the importance of the phase difference between the alternating current and the alternating potential difference. Developing the theory of the power factor he gave a very simple geometrical explanation of electrical resonance. In recent years he invented a vibratory type of phase advancer and pointed out that considerable economies might be effected by using these machines in everyday supply.

Kapp was a past president of the Institution of Electrical Engineers and was president of the Engineering Section of the British Association in 1913. Personally he was of a very kindly disposition and was always pleased to give his colleagues the benefit of his great engineering experience. He was most hospitable, and was learned in many branches of study outside his professional work.

A. R.

MRS. J. A. OWEN VISGER.

READERS of natural history works at the end of the last century were somewhat mystified as to the authorship of a number of books published under the pen-name of "A Son of the Marshes," with the editorship of "J. A. Owen." The latter was the name under which Mrs. Jean A. Owen Visger preferred to be known, whose death at Ealing on July 30, in her eighty-first

year, we much regret to have to record. Mrs. Visger was a woman of considerable attainments, with a good deal of masculinity in her character, both mental and physical. She had an absorbing interest in anything appertaining to Nature, and her mind was a storehouse of material acquired during her long life. Her powers of observation were great, and she used to the full in her literary work the excellent memory which Nature had given her, and the many opportunities which travel afforded her.

The real "Son of the Marshes" was understood to have been a working naturalist in Surrey, but it is probable that J. A. Owen's editorship went a good deal further than mere editing. One might say, in effect, that the books were practically written by her. They contained much interesting natural history gossip, following the Richard Jefferies style, but, as a rule, the information was quite unlocalised, and so lost much of its scientific value. The books followed rapidly on one another, and amongst them may be mentioned, "From Spring to Fall," "With the Woodlanders and by the Tide," "Annals of a Fishing Village," "Within an Hour of London Town," "Forest Tithes," and "On Surrey Hills"

Mrs Visger was twice married, first in 1863, in which year she went to live in New Zealand There she remained for five years, visiting Tahiti and the Sandwich Islands. She returned to reside in England in 1876, and married again in 1883, afterwards travelling considerably in Europe and in the Pacific She finally returned to England in 1913 Beside a few books of travel, Mrs. Visger wrote, "Forest, Field, and Fell," "Birds in a Garden," "Birds Useful and Birds Harmful," and in collaboration with the late Prof. G S Boulger, "The Country Month by Month" Her books are not now read, perhaps, so much as they deserve to be.

Prof. H. Battermann.

Hans Battermann, who died in Blankenburg, Harz, on June 15, at the age of sixty-two, has left a record of much useful work in astronomy. In his youth he studied at Berlin University under Forster and Tietjen, gaining the degree of doctor in 1881 for a dissertation on aberration. After a short period at Hamburg Observatory he returned to Berlin as a member of the Commission which was appointed, under the direction of Auwers, for the discussion of the results obtained at the transits of Venus in 1874 and 1882. During this period he observed a long series of occultations of stars by the moon, utilising them to obtain a value of the moon's parallactic inequality, and hence of the solar parallax; the value that he found for the latter was 8·789″, which is a good approximation to the accepted value; a still longer series of occultations, observed near the first and last quarters of the moon, should give a very accurate solar parallax. Battermann also conducted two other useful investigations at this time, one on the nature of the images in a heliometer, the other a triangulation of the Pleiades with that instrument. In 1888 he observed for nine months at the Gottingen Observatory; on his return to Berlin he took the chief part in the star observations with the transit circle, and in their reduction to a Catalogue, including the discussion of proper motions.

In 1904 Battermann was appointed professor and director of the University Observatory at Konigsberg; he continued there his researches on proper motion, and also observed further occultations with the 13-inch refractor. He was compelled to resign his professorship in 1919 through a complete breakdown in health, brought on by overwork, he retired to Blankenburg, where he died three years later, after much suffering.

A. C. D. C.

Current Topics and Events.

Dr M. O Forster, who, since November 1918, has been director of the Salters' Institute of Industrial Chemistry, is relinquishing this post at the end of next month, having been appointed director of the Indian Institute of Science, Bangalore He expects to take up his new duties early in November

A new biological station for the study of limnological problems and for research on the development of fresh-water fishes has been established at the Lake of Trasimeno, in Umbria The University of Perugia has assumed responsibility, and the director of the station is the professor of physiology, Dr Osvaldo Polimanti Further details of the equipment are promised at an early date

The excavations at the Meare Lake Village, near Glastonbury (Shapwick and Ashcott are the nearest stations), will be resumed by the Somersetshire Archæological and Natural History Society on August 25, and continued until September 9 (exclusive of the filling-in) As in previous years, the work will be under the personal direction of Dr. Arthur Bulleid and Mr H St George Gray The antiquities discovered in past years at Meare are exhibited in the Somerset County Museum at the society's headquarters, Taunton Castle, while those from the Glastonbury Lake Village (described in two royal quarto volumes) are to be seen, for the most part, in the Museum at Glastonbury Donations are needed and will gladly be received by Mr St George Gray, at the Somerset County Museum, Taunton

One of the oldest organised scientific societies, the "Schweizerische Naturforschende Gesellschaft," is holding its 103rd Annual Meeting at Berne on August 24-27 In addition to the usual business of the society, there will be scientific discussions, and a number of important papers will be read, including. "The Trend of Modern Physics," Dr C E Guye (Geneva), "The Nature of the so-called General Neuroses," Prof Sahli (Berne), "The Aar Massif—an Example of Alpine Granitic Intrusion," Dr. E Hugi (Berne), "The Natural Form of Substances as a Physical Problem," Dr V Kohlschutter (Berne), "Experimental Genetics in regard to the Law of Variation" (illustrated by lantern slides), Dr A Pictet (Geneva); and "Investigations into the Physiology of Alpine Plants," Dr G Senn (Bâle) Banquets will be held at the end of each session, and there will be concerts

and other social functions. Those wishing to take part in the meetings may do so on payment of a fee of thirty francs, payable to the "Postcheckkonto No III. 1546" of the "Naturforschende Gesellschaft," Berne.

AMONG the Civil List Pensions granted during the year ended March 31, 1922, and announced in Parliamentary Paper, No 137, just published, we notice the following — Lady Fletcher, in recognition of the services rendered by her late husband (Sir Lazarus Fletcher) to science, and in consideration of her circumstances, 60*l*, Dr. Francis Warner, in recognition of the services rendered by him in his investigations into the mental and physical condition of defective children, and in consideration of his circumstances, 100*l*; Sir George Greenhill, F R S, in recognition of his services to science and his ballistic work, and in consideration of his circumstances, 125*l*, Mrs J M Miller, in recognition of the services rendered by her late husband (Dr N H J. Miller) to agricultural science, and in consideration of her circumstances, 50*l*., Mrs Alice Mabel Ussher, in recognition of the services rendered by her late husband (Mr W A E Ussher) to geological science, and in consideration of her circumstances, 50*l*, Mrs Agnes E Walker, in recognition of the services rendered by her late husband (Mr George W Walker, F R S) to science, and in consideration of her circumstances, 75*l*, The Misses Ellen C, Gertrude M, Alice B, Katherine E and Mary L Woodward, in recognition of the services rendered by their late father (Dr Henry Woodward, F R S) to geological science, and in consideration of their circumstances, 125*l*

ON August 19, 1822, a hundred years ago, died Jean Baptiste Joseph Delambre, the illustrious astronomer and permanent secretary to the Paris Academy of Sciences Born in Amiens, September 19, 1749, Delambre became a student in Paris and first gained a livelihood as a translator and a tutor A friendship with Lalande led him to astronomy, and among his earlier work was the formation of tables of Herschel's newly-discovered planet Uranus With the revolution came the proposal for a rational system of weights and measures, and on the formation of a commission to carry the scheme through, Delambre and Méchain were instructed to measure an arc of meridian from Dunkirk to Barcelona Often interrupted, this great work occupied the years 1792 to 1799, while the results were given fully in Delambre's "Base du Système métrique decimal," published in 1806–10 Various appointments fell to Delambre, in 1807 he succeeded Lalande at the Collège de France, and as secretary to the Academy of Sciences he wrote many *éloges* and reports His later years were largely devoted to the writing of his great history of astronomy, five volumes of which appeared during 1817–1821, while the final volume was published five years after Delambre's death. Delambre is buried in the Père la Chaise Cemetery.

MR. H. G. SMITH, formerly assistant curator and economic chemist at the Sydney Technological Museum, has been awarded the David Syme Research prize of the University of Melbourne. The prize, which consists of a medal and a sum of 100*l*, is awarded for the best thesis based upon original scientific research connected with the material and industrial development of Australia Mr Smith is the leading authority upon the chemistry of the essential oils of the eucalypts. Working largely in collaboration with his botanical colleague, Mr R T Baker, and as a result of nearly thirty years' assiduous research, he has been able to establish a remarkable correlation between chemical and botanical characteristics in this complex genus, and an evolutionary theory accounting for the formation of the various species of Eucalyptus has been advanced by him and Mr. Baker. Since his retirement from the Sydney Technological Museum, Mr Smith, although in his seventieth year, has been actively engaged in further work in the Organic Chemistry Department of the University of Sydney, in association with Prof Read.

IN accordance with its policy of promoting scientific investigation in Australia, the Australian National Research Council has decided to publish a quarterly catalogue, comprising a list of titles, authors, and journals of publication of scientific research papers of Australian origin, whether appearing in Australian or other journals The catalogue, which will also contain a brief abstract supplied by the author of each paper concerned, will be entitled *Australian Science Abstracts*, and will be under the control of an editorial committee representing the various branches of science corresponding with the sectional arrangement The personnel of the editorial committee is as follows Prof H G Chapman, Dr L A Cotton, Mr J J Fletcher, Mr A Gibson, Prof J Read, Prof O U Vonwiller, Mr G A Waterhouse, and Prof R D Watt, with Dr A B Walkom as editor-in-chief The catalogue will be published in Sydney, it will be issued free of charge to members and associates of the Australian National Research Council, and a number of copies will be used for exchange purposes It is hoped to issue the first number this month

EXCEPTIONALLY heavy rains fell in many parts of England during the August Bank holiday week-end and the following days, causing not only discomfort but doing also a large amount of damage in several districts The primary cause of the rainfall was the arrival of a cyclonic disturbance from the Atlantic, the core or centre of the storm being situated near the Land's End at 8 A M on Sunday, August 6, reaching Portland by 2 o'clock in the afternoon, and passing over the Isle of Wight at 7 o'clock in the evening It was a few miles to the north-west of London at 8 A M on August 7, and passed over Cambridge at 2 o'clock in the afternoon, reaching Spurn Head by 7 o'clock in the evening The disturbance had arrived near Flamborough Head at 2 A M on August 8 and afterwards passed away over the North Sea, but the arrival of another disturbance occasioned a renewal

of the rains During the 12 hours ending 6 P.M. on August 6 the fall of rain at Bournemouth was about 1¾ inches. At Harrogate the aggregate rainfall was nearly 5 inches for the three days ending Wednesday, August 9 Nottingham registered 3·4 inches of rain for the 24 hours ending 7 P M on August 7. Sheffield experienced exceptionally heavy rain on this date, which occasioned floods, and there was a renewal of the floods in the late evening of the following day. At Leeds, between the morning of August 7 and midday of August 9 the rainfall measured 3.44 inches, which is said to be the highest ever recorded in the city At Melton Mowbray the rain measured 4·83 inches for the 24 hours ending 9 P M on August 7, and at Doncaster the measurement was 4·08 inches between midnight on August 6 and 6 30 P M on August 7 Violent thunderstorms occurred generally in the south and east of England, and in London on the afternoon of August 9 a storm was accompanied by a heavy fall of hail. At Hampstead the hailstones remained unmelted on the ground for several hours.

SWATOW, situated on the China coast at the mouth of the river Han and in the Formosa Strait, was visited by a typhoon of terrific violence during the night of August 2-3; the storm lasted about six hours, starting at 10 P M on August 2 The pre-war population of Swatow is given as 60,000, and an estimate, made a week after the disaster, of the loss of life at Swatow and the surrounding district is said to be probably 50,000. Six other towns besides Swatow are said to be destroyed. The water rose quite suddenly, partly submerging houses and buildings. Trees were uprooted and telegraph poles blown down Sampans and native craft were blown hundreds of yards inshore, most of the occupants being drowned, and many large vessels were driven ashore. More than 2000 vessels annually enter the port The occurrence and characteristics of typhoons in the China Seas have long been studied and are comparatively well understood. The recent storm was probably one of the type shown in the "Barometer Manual for the use of Seamen" published by the Meteorological Office. The period of occurrence is from June to September. These storms usually originate in the neighbourhood of the Philippines and travel northward or north-eastward, striking or skirting the China coast and afterwards passing near to Korea and Japan. The typhoons are commonly warned from Manila or Hong-kong, but the warning can, at the best, only lessen the amount of damage The Hong-kong Government has greatly aided in relieving the distress occasioned, and the British have been helped in this by the Japanese. In the Backergunge, Bay of Bengal, cyclone, in October 1876, the loss of life by drowning was estimated at 100,000, and the deaths afterwards from disease directly due to the inundation added another 100,000 to the number

Our Astronomical Column.

CONJUNCTION OF VENUS AND JUPITER—A conjunction of these brilliant planets will occur on August 26 at 18h G M T, when Venus will be 2° 29′ south of Jupiter. Venus will set at 8h 11m, and Jupiter will set at 8h 24m G M T Sunset occurs at 7h G M T, so that the two planets will set about 1¼ hours after the sun. Twilight will be very strong in the western sky just before the setting of the two planets, and in order to observe them it will be necessary to look from a position which commands a clear open view of the western sky near the horizon

On August 25 Venus and Jupiter will be in conjunction with the moon soon after midnight following the date mentioned, and on August 30 will be in conjunction with Mars in the evening The western sky during the last week of August will be extremely interesting, the new moon being there and Venus, Jupiter, and Saturn also visible in the same region.

THE ORBITAL DISTANCES OF SATELLITES AND MINOR PLANETS—Prof. G Armellini in 1918 published a law of planetary distances in the form $1\ 53^n$, where n is given successive integral values from -2 for Mercury to $+8$ for Neptune. The two integers $+2$ and $+3$ are assigned to the asteroids, while $+6$ is left unused. It can scarcely be claimed that (except in the case of Neptune) it shows great superiority over the law of Bode. However, in a further paper (*Scientia*, August 1922) he notes that his colleague Prof. Burgatti has applied the law to the satellite systems of Jupiter, Saturn, and Uranus, the formulæ being $1{\cdot}80^n$, $1{\cdot}34^n$, and $1{\cdot}31^n$ respectively. In the case of the Jupiter family the indices are -3, -2, -1, 0, $+1$ for V and the four bright satellites, $+2$, $+3$ are unused, $+4$ is assigned to the two satellites VI, VII, while $+5$, $+6$ are given to VIII, IX respectively. The author erroneously gives a distance to IX half as great again as that of VIII. The two in reality form a twin pair like VI, VII. Since the law gives no explanation of vacant spaces or of pairs of satellites, its claims to rest on a physical basis are not convincing.

The remainder of the paper deals with the asteroid-orbits. The gaps at the distances where the periods are half and one-third of Jupiter's are not ascribed to the direct action of that planet, but to some primitive agency which determined both its distance and theirs. It is, indeed, likely that the asteroids will play an important part in future discussions on the cosmogony of the solar system.

Prof. Armellini cites an interesting point about planet 434 Hungaria. Its distance from the sun, 1·95, is the precise distance at which Leverrier stated that enormous perturbations in inclination would develop, causing oscillations of 53°. Charlier, however, pointed out that Leverrier had included only first-order perturbations; he estimated that the inclusion of higher terms would diminish the oscillation to 17° or less. Finally, Prof. Armellini himself has effected the complete integration of the expressions, using elliptic functions, and finds that the oscillation of the inclination is only 3⅛°, a quantity of the same order as that of the major planets.

Research Items.

COLOUR SYMBOLISM.—In the June issue of *Folk-lore* (vol. xxxiii. No. 2) Mr. D. A. Mackenzie contributes a paper on colour symbolism, which contains a mass of interesting facts. Egyptian colour symbolism was already old at the dawn of the Dynastic period. In ancient Europe it was restricted by the conventions of Cave art, and the range of colours used by the Cro-Magnon artists was limited and confined to earth colours only. There is clear evidence, however, that people in Aurignacian, Solutrean, and Magdalenian times attached a symbolic value to certain, if not to all, colours. Small green stones were placed between the teeth of some of the Cro-Magnon dead interred in the Grimaldi caves near Mentone—an interesting fact in connexion with the ancient Egyptian belief in the magico-religious value of green stones. The writer is, however, mistaken in extending the analogy to China, where, it is said, green jade was placed in the mouths of the dead; on the contrary, the use of green jade for this purpose was exceptional

JURASSIC BIRDS.—Dr. Branislav Petronievics, who has published several papers on fossil vertebrates in the Annals and Magazine of Natural History, now states the results of his examination of the original specimen of *Archæopteryx macrura* preserved in the British Museum (Natural History) in a paper ("Über das Becken, den Schultergurtel und einige andere Teile der Londoner Archaeopteryx") published separately by Georg and Co of Geneva. His most important conclusion is stated so modestly on p. 10 that it might easily escape recognition He feels that the differences between the Berlin and London specimens referred to Archæopteryx, which caused Dames to separate the Berlin bird as *A. Siemensii*, are sufficiently increased by his recent researches to allow of the formation of two genera He proposes therefore to include in the established order Archæornithes, Archæornis, the Berlin specimen, and Archæopteryx, the London specimen. The latter (p. 18) is held to be the more primitive type, and the shoulder-girdle (p. 24) even suggests that the two genera should fall into different families. The author perceives an early carinate type in Archæornis and an early ratite type in Archæopteryx, and indicates that a convergence of the two important divisions of birds should be found farther back in some descendant of the Lacertilia. The dinosaurs lie on a separate branch, converging with the bird-branch in some ancestral reptile. We should like to have Dr Petronievics's views on Compsognathus and Podokesaurus (NATURE, vol. 109, p. 757).

MOSQUITO CONTROL.—Apart from certain war-time measures in the neighbourhood of a few military camps, scarcely anything has been attempted in this country in the way of the reduction of mosquitoes, but an example has recently been set by the Hayling Mosquito Control, which, under the direction of Mr. John F. Marshall, is doing very useful work, both practically and experimentally. The Report just issued by this body summarises what has been done since its foundation in the autumn of 1920. It was found that in Hayling Island the two common domestic species (*Culex pipiens* and *Theobaldia annulata*) were almost negligible as pests, by far the greater part of the annoyance being caused by the salt-marsh species (*Ochlerotatus detritus*). So numerous was this species that it was roughly calculated that two million larvæ were destroyed by paraffining in a single afternoon. Although last year's drought did not seriously restrict the breeding-places of *O. detritus*, the control measures adopted proved very effective, as was shown by comparison with other places along the south coast. The very successful use of soluble cresol in small quantities as a larvicide has already been described in NATURE by Mr Marshall (June 10, 1922, p. 746). Important experiments are now being carried out to ascertain if possible the range of flight of *O. detritus*. Some kinds of salt-marsh mosquitoes, especially in North America, have been shown to make large migrations for distances of many miles. If *O. detritus* shares these habits local control work may be rendered largely unavailing, though the comparative immunity already obtained by the control goes far to show that this is not the case.

PHILIPPINE FORAMINIFERA.—Mr. J. A. Cushman has published (Bull. 100, Smithsonian Institution, U.S. Nat. Mus.) a monograph on the Foraminifera of the Philippine and adjacent seas, based on material from shallow water and from nearly 600 dredgings. The shallow water examples—from less than 30 fathoms—are characteristically tropical, most of the genera being those of similar areas in the general Indo-Pacific region, many of the species being, however, distinct. In the deeper water, 100-300 fathoms, there is an exceptional development of the Lagenidæ, and in the colder deeper parts of the region a great development of arenaceous forms, especially Astrorhizidæ and Lituolidæ—many of the characteristic genera and species of cold waters in high latitudes being represented. This supports the view that the wide distribution of these arenaceous forms in cold waters is dependent more on temperature than on depth The largest of the living calcareous Foraminifera, *Cycloclypeus carpenteri*, of which specimens about 2½ inches in diameter were obtained, was dredged in quantity in parts of the area. The systematic part of the work records 568 species and gives notes on their characters and distribution; figures of the more important species are given in 100 plates.

THE MICROSCOPIC DETERMINATION OF THE NON-OPAQUE MINERALS.—The method of identifying minerals by determining their indices of refraction by immersing or embedding their powders in media of known refractive index receives immense extension through Esper S. Larsen's memoir bearing the above title (U S. Geol Survey, Bull. 679, 1921) The tables given contain data for about 950 mineral species, and the methods of determination are adequately described

PRE-DEVONIAN GEOLOGY OF GREAT BRITAIN.—The Quarterly Journal of the Geological Society, vol. lxxviii. pt 2, 1922, shows how much work has remained to be done on the stratigraphy of our older British areas Mr. E. B Bailey develops his theory of *nappes* in the south-west highlands of Scotland, arousing thereby a healthy and critical discussion. Dr. Gertrude L. Elles gives in detail the results of her zoning of the rock-succession in the Bala district; and Dr. J. Wills and Mr. Bernard Smith have greatly extended our knowledge of the country round Llangollen.

NEW RADIOLITES AND A NEW CRINOID FROM THE UPPER CRETACEOUS OF MEXICO.—Examples of those strange aberrant bivalves the Radiolitidæ from the Upper Cretaceous of Tamaulipas, Mexico, where they appear to be scarce, have been described and figured by L. W. Stephenson (Proc. U.S. Nat. Mus., lxi. art.1), who, however, favours Lamarck's later name in his title and refers to them as belonging to the "Rudistid Group." A new genus, Tampsia, with two new

species, three species, of which two are new, of Sauvagesia, and a new species of Durania complete the series Among the associated fossils cited is *Balanocrinus mexicanus*, n sp, which forms the subject of a separate paper by F Springer (tom cit, art 5) This is the first known occurrence of the genus in America

THE FLOTATION OF CONTINENTS.—M E Gagnebin, of the University of Lausanne, has provided a masterly review of Wegener's hypothesis of the movement of continental masses over the general surface of the globe In ten pages of the *Revue générale des Sciences naturelles*, vol xxxiii p 293, 1922, he states the main features of the argument, discusses the problems raised, and furnishes references and footnotes that make his lucid essay an almost essential introduction to Wegener's "Entstehung der Continente" (see NATURE, vol 109, pp 202 and 757) It is interesting to notice that the relations of folded zones to those of subsidence on the earth is one of the subjects discussed at the International Geological Congress in Brussels in August 1922

THE MATRIX OF DIAMOND.—The question of whether diamond separates out from ultrabasic igneous magmas, or is carried up in these exceptional magmas because they have traversed deep-seated metamorphic rocks, is once more raised by the description of the diamond bearing gravels of the Somabula Forest in Southern Rhodesia (A M. MacGregor, Geol Surv S Rhodesia, Bull 3, 1921) These fluviatile beds form part of the Karroo systems, and the kimberlite pipes of S Africa are of later date The author suggests that the diamonds were washed from a kimberlite of unusually early age, since he favours the view of their igneous origin New interest is given to the kimberlite pipes of Africa by H S Harger's discovery (Trans Geol Soc, S Africa, vol xxiv p 1, 1922) that an example in the Riversdale district of the Cape Province cuts strata of Uitenhage (Cretaceous) age

CRITICAL RESEARCH ON FOSSIL BRACHIOPODA.—The transference of well-known species to new genera as investigation becomes more precise often leaves little to be said for an original genus the name of which has become known throughout the world This is sadly the case with Rhynchonella, to which Mr S S Buckman (Mem Geol Surv India, Palæontologia Indica, New Ser, vol 3, Mem 2, "The Brachiopoda of the Namyau Beds, Northern Shan States, Burma") now assigns only two species, *R loxia* Fischer of the Portlandian, and *R variabilis* Davidson of the Kimmeridgian (p. 57) The author quotes (p 91) his previous conclusion that no Mesozoic species can be assigned to Terebratula Muller, 1776. On pp 8 to 11 he describes his method of "burning" specimens of fossil brachiopods; when the shell is heated and dropped into water, it commonly flakes off from the internal cast, and the characteristic muscular scars are clearly traceable on the mould Much, of course, depends on the infilling material, and oolitic limestone yields poor results The method has been elaborated by Mr Buckman from an observation by Mr. T. H D. La Touche (p. 2), who noticed that the fossils fell out easily from material that had passed through Burmese lime-kilns, and who proceeded to treat his rocks in a big fire "with very satisfactory results."

EVOLUTION OF THE GRAPTOLITES.—The numerous geologists who wish to keep abreast of progress in the classification of Older Palæozoic strata will find much guidance in a paper by Dr. Gertrude Elles on "The Graptolitic Faunas of the British Isles" (Proc. Geol. Assoc vol 33, part 3, 1922; price 5s.). Since it seems uncertain if hydrozoan, or even cœlenterate, affinities can be maintained for graptolites and their allies, a separate class of organisms, the Graptolithina, has been established, subdivided into two orders, the rapidly changing Graptoloidea and the almost stationary Dendroidea In the same prudent spirit the term rhabdosome replaces polypary, and theca hydrotheca The virgula of older descriptions of graptolites disappears. Attention is well directed to the nema, the hollow thread-like prolongation of the apical portion of the sicula, as being the organ of attachment essential to the welfare of the rhabdosome. In the earlier pendent graptolites the nema is unprotected, but in forms regarded as scandent, such as Diplograptus, and also in some uniserial genera, it is protected, and is sometimes wrapped round the bases of the thecæ Many of the points mentioned are quoted from work published by the author and other investigators, and recognised by modern writers, such as A M Davies; but the present summary, the clear diagrams of types successively evolved, and the stratigraphical table, render this paper by Dr Elles valuable in all colleges as a supplement to established text-books of palæontology

VERTICAL CIRCULATION IN THE ATLANTIC.—A. Merz and G Wust (*Zeitschrift der Gesellschaft fur Erdkunde*, Berlin, 1922, No 1-2) discuss the nature and causes of the vertical circulation of the water of the Atlantic Ocean, reviewing the various descriptions and explanations so far published. It has been known, in a general way, that water which is relatively warm and fresh flows on the surface from the region of equatorial rains and calms north and south to the sub-tropical zones, while water which is relatively cold and dense flows in the opposite directions as under-currents. This system of drifts now appears to be of very limited depth. The superficial warm currents extend to about 50 metres while the under-currents have their main stratum at a depth of 75-150 metres from the surface The cause is differences of density rather than differences of temperature.

DUST-RAISING WINDS.—This subject is dealt with in the Memoirs of the Indian Meteorological Department, vol 22, part 7, by Dr C W B Normand Observations were made on dust phenomena in Mesopotamia in 1918, and these, together with Dr Hankin's observations in a preceding memoir, are correlated with those of other observers in other countries The camp in Mesopotamia was situated at Samarrah, near the edge of the vast low plateau known as Jezireh, where the dust in places lay knee-deep With even light winds in August and September it was no uncommon occurrence to see three or four dust-devils of great height meandering with the breeze on the plain The base of many of these was only about 5 metres in diameter and the height was at least 300 metres For the origin of dust-devils a highly unstable vertical distribution of temperature is said to be a necessity. At Samarrah the author attributes the impetus to be often due to the incinerators at the various camps for burning refuse. The "primary" dust-storm in Mesopotamia occurs principally between 4 P.M. and midnight in the months of March, April, May, and September; they are always associated with cloud, and were often followed by rain, thunder, and a marked fall in air temperature. The dust-storms in spring are almost always associated with thunderstorms and are said to be undoubtedly due to the descending currents which are known to occur in front of thunderstorms. Interesting information is given on the cause of dust-raising by wind, and on turbulence and the density of dust at various heights.

The Hull Meeting of the British Association.

PROGRAMMES OF THE SECTIONS.

THE programmes of the various Sections of the British Association for the forthcoming meeting at Hull have now been provisionally completed, and it is possible to state what are the chief subjects to be brought forward. We are indebted to the Recorders of the Sections for the subjoined outline of arrangements made for the meeting

SECTION A (MATHEMATICS AND PHYSICS).—The proceedings of Section A this year promise to be of more than usual interest. The Section is fortunate in having secured the attendance of three very distinguished foreign guests, Prof P Langevin, Prof. P. Weiss, and M le Duc de Broglie The two former will take part in a discussion which has been arranged on the origin of magnetism, to which Sir J A Ewing and Dr A E Oxley have also promised to contribute M de Broglie will read a paper, which cannot fail to attract great interest, on X-rays and Beta rays, and as Prof. R. Whiddington will make a communication on the same subject, a valuable discussion on this aspect of physics may be expected. Prof G H. Hardy has chosen as the subject of his presidential address "The Theory of Numbers," and it may be confidently anticipated that he will make it of that fascinating interest which is an attribute of all his lectures. An important and somewhat novel joint discussion will take place under the auspices of Sections A and I on physical instruments for biological purposes Prof A V Hill will open this discussion, and several biologists and physicists have promised to take part. In connexion with this discussion there will be an extensive exhibition of appropriate apparatus by Major W. S Tucker, Mr F. E Smith, Dr G Wilkinson, and The Cambridge and Paul Scientific Instrument Company In view of the success attending the experiment at Edinburgh last year, the Committee of Section A has arranged several lectures of a semi-popular character Sir William Bragg will lecture on "The Significance of Crystal Analysis", Prof J Proudman has chosen a subject especially appropriate to Hull, namely, "Tides, with Special Reference to the North Sea", and Prof H H Turner will delight the children with the topic "The Telescope and what it tells us"

SECTION B (CHEMISTRY).—The programme of Section B will include several discussions Principal Irvine has selected research problems in the sugar group as the subject of his presidential address, and this will be followed by several papers on carbohydrates from the St. Andrews laboratories. Photosynthesis will be discussed jointly with Section K (Botany), the recent work from the Liverpool laboratories on the synthesis of the more complex plant products being well represented. Sir William Bragg will describe his researches on the crystalline structure of organic compounds, and the recent theories of organic structure will be considered in a discussion on valency and polarity, to be opened by Prof Robinson, and in a paper by Prof. Holleman on substitution in the benzene nucleus Other separate papers include an account of the recent work on compressibilities under high pressures conducted in the Geophysical Laboratory at Washington, and a study of the properties of soap solutions by Prof. McBain. Two discussions of industrial questions have been arranged. One of these concerns the local industry of the hydrogenation of fats, which will be considered from the scientific and the industrial side, and the other is the industry of synthetic nitrogen compounds. Several of the modern processes of synthesis will be described. The city is an important centre of chemical manufactures, and visits of the Section to some of the principal works, including the fat and oil and the cement industries, have been arranged

SECTION C (GEOLOGY).—As a part of the series of discussions on questions connected with the North Sea to be held in various Sections, the first item in the programme will be an account by Prof Kendall of the geological history of the North Sea Basin from Permian times to the present day This will be followed by an account of the floor deposits of the North Sea and by a general discussion of these topics The geology of the Hull district will be described by Mr T Sheppard, whose lecture will be illustrated by lantern slides Other communications on local geology are the erosion of the Holderness Coast, by Mr. C Thompson, a new section in the Oolites and Glacial deposits at South Cave, by Mr J W Stather, and a new section in the Oolites at North Ferriby, by Mr W S Bisat Pleistocene and Recent ice conditions in North-eastern Labrador will be described by Prof Coleman of Toronto The subject of the presidential address by Prof P F Kendall is the physiography of the coal swamps The address will be followed by Prof Gilligan on sandstone dykes in the Cumberland coalfield and the subjects raised in the two communications will be discussed. A discussion on Wegener's hypothesis of continental drift, in which both the geological and astronomical sides will receive attention, has been arranged, and the relation of early man to the phases of the ice age in Britain will form the subject of a joint meeting between the anthropological, geological, and geographical sections Papers dealing with the zoning of Carboniferous rocks will be read by Mr W S. Bisat and Mr R G. Hudson, and Dr H L Hawkins will describe the relation of the Thames to the London Basin Numerous excursions will be held during the meeting

SECTION D (ZOOLOGY).—The organising committee of Section D, the president of which is Dr E J Allen, has shaped its programme for the forthcoming meeting at Hull with the view of relating it so far as possible to local interests Four of the eight sessions will be devoted to marine biological and fisheries problems, the remaining four to matters of a wide variety of interest One whole day will be given to discussion with representatives of the fishing industry, when members of the industry will propound difficulties and questions which the biologist will endeavour to answer to the limits of his knowledge, and which he will, it may be hoped, take to heart against the planning of further investigations Another feature of the meeting will be the number of distinguished foreign marine biologists who will attend. Dr Hjort, of Norway, will give an evening lecture at Grimsby, Dr C. J. Joh. Petersen will come from Denmark to open a discussion on the fauna of the sea bottom, of the quantitative study of which he is the pioneer, Dr Johs. Schmidt will give an account of his recent explorations in the Atlantic, and there will be eleven other distinguished oceanographers, including representatives from Belgium, Denmark, France, Holland, Norway, and Sweden It is anticipated that a representative gathering of research vessels will also attend, including, in addition to our British vessels, the Danish *Dana*, the French *Pourquoi Pas*, and the Swedish *Skagerak*. Of items other than those concerned with marine biology one will be a discussion

with Section K (Botany) on the present position of Darwinism, when the views of Dr. Willis and Mr. Yule, as put forward by themselves at the meeting, will come under review and criticism. Among the individual contributions it is difficult to particularise; they will deal with problems relative to hormones, hydrogen ion concentration, forestry, geographical distribution, hereditary transmission of small variations, adaptation, periodicity of pond protozoa, and the effect of lead pollution The final but not the least important item on the programme is a discussion with the Hull naturalists on the possible work of natural history societies in relation to faunal surveys.

SECTION E (GEOGRAPHY).—The presidential address by Dr. M. I Newbigin will be on Human geography: first principles and some applications. On the same day Miss E C Semple will speak on the influence of geographical conditions upon ancient Mediterranean agriculture Several speakers will deal with current problems in Europe, including Prof J F Unstead on the belt of political change in Europe, and Mrs. H. Ormby on the Danube as a waterway. Prof. P. M. Roxby will lecture on the place of Peking in the life of modern China, and Dr. Vaughan Cornish, in a paper entitled the isothermal frontier of ancient cities, will develop the interesting thesis that from the North Sea to the Sea of Japan the separation between city life and that of forest and prairie people is marked by the same mean annual isotherm. Local geography will be treated by Mr L Rodwell Jones, Mr. C B. Fawcett, and others There will be a number of papers on cartography and survey, including survey in polar regions, by Mr F. Debenham, the mapping of Latin America, by Mr A. G Ogilvie, early maps of Malta, by Dr. T Ashby, and a discussion on the use of Mercator's projection for air-maps, which, it is hoped, will be opened by Col E. M Jack. A joint discussion, with the cosmical subsection of Section A, on the monsoons, will be opened by Dr G C. Simpson. Section E will also take part in a joint discussion with Sections C and H on relations of early man to phases of the ice age in Britain. Travel will be represented by Sir P. Brocklehurst on his recent journeys through Wadai, Mr. R. R. Walls on his extensive wanderings in Portuguese Nyasaland, and Mr. R. A Frazer on some work in Spitsbergen. In economic geography Mr H M Spink will speak of some geographical aspects of recent developments of water power, Mr. A. V. Williamson on irrigation in the Indo-Gangetic alluvium, and Mr D C T. Meckie on the trend of world commerce. An excursion to Spurn Head and Sunk Island is being arranged

SECTION F (ECONOMIC SCIENCE AND STATISTICS) — The influence which the war has had upon our economic life is again the subject of several of the papers which are to be read in this section. Prof. A. L. Bowley will continue his studies of post-war prices in a paper comparing wholesale and retail prices since the Armistice, and Mr W. H. Whyte is contributing a paper on the war and its influence on stock markets The questions of unemployment and of out-door relief are to be dealt with by Mr J. L. Cohen in a paper on the future of unemployment insurance; and by Miss Anne Ashley, who has had considerable experience of social work in Edinburgh, and is contributing a paper on the English and Scottish Poor Law in relation to the able-bodied. The measurement of productivity in agriculture and industry is to be dealt with by Mr R. B Forrester; human motive in industry by Miss H. Reynard; and modern municipal markets and their economic significance, by Prof. J. G. Smith. The president of the section is Prof. F. Y. Edgeworth, and his address will deal with the question of equal pay to men and women for equal work. In addition to the papers there are to be two important discussions with other sections—the first with the Sections of Agriculture and Physics (Meteorology) on weather cycles in relation to agriculture and industrial fluctuation. It will be opened by Sir William Beveridge and Mr. R. A. Fisher. The second discussion is with the Agriculture Section, and is to discuss the possibility of increasing the food supply of this country. Sir Henry Rew, Sir John Russell, Mr. C. S Orwin, Sir Thomas Middleton, Prof Somerville, and Prof. Cannan have promised to speak. Both these discussions deal with very urgent problems at the present time, and they should prove of considerable interest not only to members of the Association but to the general public.

SECTION H (ANTHROPOLOGY).—This Section has a varied programme, in which matters relating to archæology predominate. It includes two organised discussions—one dealing with the antiquity of man in relation to the ice age in Britain, which will take place in a joint session with the Geological and Geographical Sections, and one, to be held in a joint session with the Psychological Section, on mental characters and race, which will be opened by Prof. J. L. Myres. One morning session will be devoted to questions relating to the archæology and anthropology of the north-east coastal area of England, when Mr. Leslie Armstrong will discuss the Maglemose remains of Holderness and their Baltic counterparts, Mr. W G. Collingwood will deal with the influence of Scandinavia on the art of the Danelaw in the tenth century, and Prof. A Mawer will consider the place-names of the East Riding. In connexion with this group of subjects Prof. A. W. Brøgger of Christiania will describe the burial found in a Viking ship at Oseberg, which is of great importance for our knowledge of Scandinavian art and culture in the ninth century Lord Dunsany will describe recent finds of palæolithic implements in North Africa, and Mr. Seton-Karr will deal with aspects of the same subject; Miss Nina F Layard will discuss prehistoric cooking places, and the excavations carried out by the Spelæological Society of Bristol University in caves in the Mendips, which have brought to light remains of the late Paleolithic and Iron Ages, will be described by Mr E K Tratman and Mr J A. Davies A communication by Mr Cyril Fox, which is likely to give rise to an interesting discussion, deals with the distribution of population in the Cambridge region with special reference to the bronze age Dr. T. Ashby will give an account of archæological investigations carried out in Italy during the last twelve months, as well as of certain supplementary investigations made by himself at the megalithic temple of Hal Tarxien in Malta. Miss Murray also will describe the excavations which she is now carrying on in the same island. Mr Stanley Casson will give an account of his recent excavations in Macedonia, and discuss their bearing upon certain general problems. This communication, in conjunction with one from Mr. J Whatmough on inscribed fragments of stagshorn from North Italy, of which the inscriptions are in an unknown language, should give rise to fruitful discussion on racial movements in Europe in late prehistoric times. In physical anthropology Prof W. J. Sollas will discuss comparative craniometric methods, with special reference to Neanderthal Man; and in ethnography the two most important communications will be a description of rock-paintings from New Guinea by Dr. W. M. Strong, and an account of certain peoples of the Congo area by Mr. E. Torday. The latter will deal incidentally with the question of the decay of custom among primitive peoples.

SECTION I (PHYSIOLOGY).—The section of physi-

ology can congratulate itself on an exceptionally good programme. Local effort is well represented, for the first morning session, as well as parts of other sessions, are occupied by papers contributed by Hull members of the medical profession. The meeting will open with a paper by Dr F. C Eve, senior physician to the Hull Infirmary, on "Life and Energy: an Interpretation." Dr T Ritchie Rodger is to follow with a paper on "The Effect of Loud Noises on the Cochlea," in which he will discuss the consequences of the boiler-making industry in causing damage to the organ of hearing. A demonstration of a model of the cochlea, by Dr G Wilkinson of Sheffield, is also of interest in this connexion. The investigation of the movements of the alimentary canal by means of the X-rays will be described and demonstrated by Dr J E Barclay. Prof A. V Hill will read a paper on athletics and oxygen supply, in which he will show what a large debt of oxygen becomes due to the body in severe exertion, to be called in during the succeeding period of rest. The presidential address, by Prof E P Cathcart, on the "Efficiency of Man and the Factors which Influence It," will deal with another aspect of muscular work which Prof Cathcart has studied, in America with Dr Benedict, and at home in connexion with the energy requirements of recruits. There are two interesting joint discussions with other sections. With the section of physics there is to be a discussion on the application of physical methods to biological investigations, to be opened by Prof A V Hill, while with the section of agriculture there will be a discussion of the popular topic of the vitamins, to be opened by Prof J C Drummond. In this discussion we welcome a paper by Dr Atherton Seidell of Washington, who has done outstanding work on the isolation of vitamins. The foreign guest of the section, Prof W Storm van Leeuwen of Leyden, will contribute two interesting papers on hypersensitiveness, a subject of considerable importance in relation to the causation of asthma, hay fever, and serum sickness. The section is fortunate in securing two eminent physiologists to deliver popular lectures —Mr J Barcroft on the expedition which he recently led to Peru for the study of mountain sickness in the Andes, and Prof W D Halliburton, who will lecture on "Our Bones and Teeth." Dr F W Edridge-Green will give two papers on colour vision, Dr P M Tolmie of Hull one on the cytology of the blood, and Dr J H Burn a contribution to the physiology of sweating, in which he shows how certain clinical facts can be explained on physiological lines.

SECTION J (PSYCHOLOGY).—The new psychological section of the British Association met for the first time last year at the meeting held at Edinburgh. Judging by the programme announced, it should have an equally successful session this year at Hull. Unfortunately, however, it has already sustained a grave and lamentable loss by the death of Dr W H R Rivers, the elected president. Dr C. S Myers, who has just given up his Cambridge post to become director of the new National Institute of Industrial Psychology, is taking the chair in Dr Rivers' place, and his presidential address will deal with the influence of Dr Rivers' work on the development of psychology in Great Britain. The first important feature in the programme will be the opening discussion upon industrial psychology. In this Dr Myers, Dr Miles, Mr J Seebohm Rowntree, and Mr. Eric Farmer are taking part. The two first speakers will doubtless describe the work proposed, and the work hitherto carried out, by the National Institute, in the establishment of which they have had so prominent a share. Mr. Farmer is reporting an investigation on "Output Curves as Measures of Fatigue"—an inquiry carried out under the Industrial Fatigue Research Board—and Mr. Rowntree is describing the results of some group-tests of intelligence applied to the employees at the big factory at York. Friday morning, September 8, will be devoted to a joint discussion with the Section of Educational Science upon psychoanalysis and the School. In this the chief speakers will be Dr. Kimmins, Dr Crichton Miller, Prof Pear and Dr. R G Gordon. The other joint discussion will be that held in conjunction with the Anthropological Section on Tuesday morning, September 12, when Prof J L Myres, Prof A A Fleure, and Dr C S Myers are holding a symposium on mental characteristics and race. On the same afternoon there will be a similar symposium on mental deficiency, in which Dr Auden (the School Medical Officer for Birmingham) and Dr Shrubsall (the Assistant School Medical Officer for London) will both take part.

SECTION K (BOTANY).—Under the presidency of Prof H H Dixon, Section K has a very full and varied programme for the Hull meeting. The president's address will deal with "The Transport of Organic Substances in Plants." An interesting feature of the programme will be the joint discussions on photosynthesis (with Section B) and on the present position of Darwinism (with Section D). The discussion on photosynthesis will be opened by Dr F F Blackman with a paper on the biochemical problem of chloroplastic photosynthesis, which will be followed by Profs Baly and Heilbron with accounts of their recent important researches upon carbon and nitrogen metabolism in green leaves. Contributions to this discussion will also be made by several other botanists and chemists. An animated discussion is expected upon the present position of Darwinism, which will be opened by Dr J C Willis, who will treat of "The Inadequacy of the Theory of Natural Selection as an Explanation of the Facts of Geographical Distribution and Evolution." He will be followed by Mr Udny Yule, with a paper on "A Mathematical Concept of Evolution based on the Theory of Age, Size, and Space." Mr C Tate Regan will then enter the arena, and, it is understood, will attack the Willis-Yule position from the zoological point of view. Other speakers will include Prof Johannsen (Denmark), Dr J T Cunningham, and Dr H Wager. Persons interested in forestry are again linked with Section K as at Edinburgh, and a morning is to be devoted to papers on forestry, the most important of which is one by the Right Hon Lord Lovat (Vice-President of the section) on the position of British forestry to-day. The popular lecture is to be given this year by Prof Dame Helen Gwynne-Vaughan, who will take "Moulds" as her subject. The remainder of the programme is representative of many different branches of botany, including plant physiology, genetics, cytology, mycology, anatomy, and ecology. Thanks to the local botanical committee, a fine excursion programme has been arranged, including visits to Spurn Head, Skipwith and Riccal Commons, and Brantingham Dale. In addition, permission has been given to members interested in forestry to visit Lord Yarborough's woods by the kindness of the owner.

SECTION L (EDUCATIONAL SCIENCE).—The proceedings of this section will open at 10 A.M. on Thursday, September 7, with an address on "Educational and School Science" by the president, Sir Richard Gregory. The address will be used to open discussion upon what should be the character and content of school science courses in the general education of all up to about sixteen years of age. Prof. J. Arthur Thomson will be one of the speakers on this subject. After the discussion there will be a paper on advanced instruction in elementary schools by Mr. R. C. Moore.

Lord Haldane had arranged to give an address in the afternoon, but unfortunately he has had to cancel all public engagements for reasons of health. Two important meetings will be held on Friday, September 8. In the morning there will be a joint meeting with the Psychological section for the discussion of psycho-analysis in relation to the school. The opening speakers will be Dr. C. W. Kimmins, Dr Crichton Miller, Prof Pear, and Dr. R. G. Gordon. In the afternoon, addresses on Imperial Citizenship will be given by the Rt Hon. Lord Meston and the Rt. Hon. Sir Joseph Cook (High Commissioner for Australia). Bishop Welldon will also speak. On Monday, September 11, there will be a paper on international students' organisations, by Mr. Iveson S. Macadam (President of the National Union of Students), and a discussion on English as the basis of national education, at which the speakers will include Mr. G. R. Pocock (Dartmouth College), Prof. Edith Morley, and Dr F. S. Boas. The morning of Tuesday, September 12, will be devoted to local educational work, and the papers will be on the movement towards individual work in schools, with special reference to experiments in Hull, by Miss F. Sayer; and on the Dalton Plan, by Miss C. T. Cumberbirch. In the afternoon there will be a joint discussion with the engineering section on the effect of reformed methods in teaching mathematics, to be opened by Prof P. T. Nunn and Mr. R. C. Fawdry (Clifton College).

The Imperial Cancer Research Fund.

THE executive of the Imperial Cancer Research Fund can look with satisfaction on twenty years of steady progress towards the understanding of the nature of tumours. In the twentieth annual report, lately issued, the director, Dr J. A. Murray, records once again a tale of sound and solid work in a field which is rather particularly liable to be overrun with hasty and slipshod frontal attacks and premature attempts to find a cure for cancer.

Of chief interest perhaps are Dr Drew's experiments on the growth of normal and malignant tissues *in vitro*. Observations on the transplantable tumours of mice have shown that malignant tissue has no natural duration of life, the same tumour growing continuously under favourable conditions for a period far longer than the normal life of the animal in which it arises. Similarly, experiments on the continuous culture of normal tissue *in vitro* show, with a certainty which will increase with further lapse of time, that they too may achieve an analogous immortality. The fundamental functional characteristic of tumours is their independence of, and dissociation from, the rest of the body in which they grow. If normal tissues are subjected to the same dissociation by isolation in artificial cultures, they too appear to be capable of continuous life without the intervention of sexual regeneration.

Dr Drew has now analysed this question of the influence of different tissues on one another to a further point. He finds that epithelial cells when growing in pure culture remain undifferentiated. When connective tissue cells are added to such cultures, differentiation sets in with little delay, squamous epithelium producing keratin in the familiar form of the concentric corpuscles so well known in human epitheliomata and mammary epithelium growing into branching acinous structures.

The form of the cells depends, then, more on where they are than on their origin, and the facts form an interesting commentary from the experimental side on the views of Dr G. W. Nicholson on heteromorphosis in tumours put forward in his essays in recent numbers of the Guy's Hospital Reports. Dr. Drew has discovered also the curious point that malignant cells quickly make the fluid in which they grow unsuitable for further multiplication, though normal tissue will still grow in it readily. Continuous culture of malignant cells requires more frequent transplantation than do normal tissues, exemplifying the observational fact that human tumours are less resistant than normal tissues to all sorts of harmful influences—infections, poisons such as arsenic, radiation of different kinds, and so forth. They are superior to normal tissues only in their capacity to override the rules governing normal growth differentiation and morphology.

Drs Cramer Drew and Mottram have continued their studies of vitamin deficiencies. Defect of vitamin A produces characteristically a diminution in the blood platelets, just as absence of vitamin B leads to almost complete disappearance of lymphoid cells. Similar changes in the blood elements may be induced by X-rays and radium. No success was obtained in attempts to influence the growth of transplanted tumours by vitamin deficiencies. In continuation of the production of malignant epithelial tumours by the repeated irritation of the skin by tar and similar substances, Dr. Russell now records the generation of malignant tumours of connective tissue by its subcutaneous administration. He also records further progress in his study of the respiratory exchange of tumours.

European Fish in New Zealand Waters.

A VERY useful account of the Marine Biological Station and Fish Hatchery at Portobello in New Zealand has been prepared by the Hon G. M. Thomson and the late Mr Thos Anderton, and is published as Bulletin No. 2 of the Board of Science and Art of the Dominion. There is an appreciative note about Mr. Anderton, a man of great practical ability, who began life as a mercantile marine officer and then became a marine zoologist: he organised the Portobello Station with conspicuous success. The work of this institution is remarkable for the very original experiments carried out in connexion with it, having in view the naturalisation of European fishes and other marine edible animals in New Zealand waters. These attempts are well known in a general way, but it is well to have detailed records of their methods and results.

The main object was to introduce the European herring, turbot, edible crab and lobster. The herring was taken over in the form of large numbers of fertilised ova and the turbot in the form of small immature fishes. Undismayed by unfavourable reports by various ichthyologists, a number of preliminary experiments were made in order to discover whether the rate of development of herring ova could be retarded by the employment of low

temperatures so that the eggs could be carried through the tropics and would hatch at about the end of the journey to New Zealand.

Prof. J. Cossar Ewart and Dr. H. C. Williamson made the preliminary experiments and Mr. Anderton devised the water-cooling and circulating apparatus, which was fitted up in a cold room on an ordinary commercial vessel. As fishery zoologists well know, it is not easy to collect large numbers of healthy, fertilised herring eggs, but this was successfully done at Lowestoft by Mr. Anderton, and the ova were made to adhere to glass plates, which were then transferred to the apparatus on board ship. The water was kept at a temperature a little above 0° C. and was circulated over the eggs. The experiment would have been quite successful but for a breakdown in the tank arrangements of the ship. It has not been repeated, though it is now evident that the method presents no insuperable difficulties. The young turbots and the pregnant edible crabs and lobsters were taken out to New Zealand without any difficulty and were successfully "planted" there

So far there is no proof, however, that these species have established themselves in their new environment. The ingenuity displayed in these experiments and the eminently practical methods employed are of much interest and well deserve permanent record.

University and Educational Intelligence.

EDUCATIONAL legislation in America in 1919 and 1920 is reviewed by one of the specialists of the Washington Bureau of Education in Bulletin No 13 of 1922 Of the many problems connected with education which have been dealt with by the State Legislatures since the war, several are, or have lately been, subjects of controversy in this country The proportions in which the cost of supporting schools is shared between the general tax-payer and the rate-payer have been changing at the expense of the former throughout the States, "including the South, where the State, as such, is already relatively a very large contributor and where the need is rather for the further development of local educational spirit" In the State of New York the increase in appropriations for schools amounted to over twenty million dollars, which was added for the purpose of raising teachers' salaries Texas appropriated four million dollars for the same purpose Many of the States passed salary laws more or less on the lines of the "Burnham scales" Under an Iowa act, for example, a schedule of minima is prescribed, the lowest being 50 dollars a month, while a teacher who has received a degree upon completion of a four-year college course and holds a State certificate must be paid not less than a hundred dollars a month, and after two years of successful experience not less than a hundred and twenty. Teachers' superannuation systems are of recent origin in the United States, very few having been established earlier than the beginning of the present century. Nearly half of the States now have systems established by law for the entire State, and nearly a third have laws for certain cities only Tendencies in recent pension laws are in general towards a larger participation of public funds in the support of the system, a more thorough application of scientific actuarial data, and more business-like administration. Extensions of the age limits of compulsory education have been effected recently in many States, the upper limit being in many cases raised to sixteen, while the lower limit is commonly seven or eight years.

Calendar of Industrial Pioneers.

August 20, 1769. Gabriel Jars died.—A native of Lyons and born in 1732, Jars acquired a practical knowledge of mining under his father, and after studying at the École des ponts et chaussées, made a long tour of inspection of the mines of England, Scotland, Sweden, Holland, Austria, and other countries, the results of his observations appearing in his "Voyages métallurgiques" published after his death

August 21, 1884. Henry Wimshurst died.—For many years a shipbuilder at Millwall, Wimshurst was an ardent supporter of Pettit Smith in his endeavours to introduce screw propulsion, and, with the aid of friends, in 1838 he built the *Archimedes*, the vessel which first demonstrated the value of the screw for propelling ships in the open sea, and in 1839 he built the *Novelty*, the first screw steamer to make a commercial voyage

August 23, 1836. Louis Marie Henri Navier died.—A distinguished professor of engineering, known for his mathematical investigations, Navier was an engineer in the Corps des ponts et chaussées, and at the time of his death was professor of analysis and mechanics in the École Polytechnique

August 24, 1860. Jesse Hartley died.—The son of the master bridge-builder to the county of York, Hartley succeeded to his father's position, and in 1824 became engineer to the Liverpool docks, in which capacity he planned and executed with complete success the most extensive dock works in the world.

August 25, 1819. James Watt died.—Acknowledged to be the greatest engineer of modern times, Watt made his great discovery of the separate condenser in 1765, while engaged on the repair of a model of a Newcomen atmospheric steam engine for Glasgow University This improvement in the steam engine was followed by his patents of 1769, 1781, 1782, and 1784, which collectively transformed a rude and imperfect contrivance into an efficient and powerful machine, providing the miner with his pump, the smelter with his blast, and the weaver with his power-house. From his early boyhood Watt was given to scientific pursuits, and all his work was the result of the application of scientific principles to practical problems Born in Greenock, he became instrument maker to Glasgow University, and after some years of civil engineering, in 1775 entered into partnership with Matthew Boulton, the founder of the Soho Manufactory Watt died at Heathfield House, close by Soho, and was buried in Handsworth Church.

August 25, 1862. James John Berkley died.—Trained under Bidder and Robert Stephenson, Berkley in 1840 was appointed Chief Resident Engineer of the Great Indian Peninsular Railway, and as such projected and carried through with the highest skill the line of railway from Bombay to Calcutta.

August 26, 1845. Philippe Henri de Girard died.—Famous as a chemist, a mechanician, and technologist, Girard was born on February 1, 1775, and after the French Revolution had soda factories at Marseilles and Paris. The offer by Napoleon in 1810 of a prize of a million francs for flax machinery led Girard to devise new machinery and establish flax mills, but he received no prize. After the Restoration he lived mainly in Austria and Poland, promoting steam navigation on the Danube, and carrying out extensive operations in manufactures, metallurgy, and practical engineering at Warsaw.

E. C. S.

Societies and Academies.

PARIS.

Academy of Sciences, July 17.—M. Emile Bertin in the chair.—H. **Deslandres** and V. **Burson**: Researches on the atmosphere of the stars. Properties of stars which have the same radiations and the same chromospheric layers as the sun: a list of twelve stars is given, all of which show bright lines; eleven of these are yellow stars of types G and K (Harvard classification), one only is of the M_a type. These stars possess chromospheres relatively more luminous and more important than those of the sun.—Charles **Moureu** and Charles **Dufraisse**: Auto-oxidation. Anti-oxygenic power. Various phenomena relating to anti-oxygenic action. It has been shown in an earlier communication that certain substances, of which hydroquinone is the type, can prevent oxidation. The reaction between acrolein and oxygen has been studied quantitatively, when the proportion of hydroquinone present has been varied between $\frac{1}{10}$th and $\frac{1}{1000000}$th of the acrolein present, and the results given in graphical form. Various phenols are classified according to their power of retarding oxidation ("anti-oxygenic power"). A summary is given of earlier work bearing on the subject.—Maurice **Leblanc**: Lamps with three electrodes, anode, cathode, and intermediate grid where the current is carried by ions, and their applications. It is shown how these lamps can be used to transform a continuous current in an alternating current of high frequency or to transform high-frequency currents into alternating currents of low frequency.—Jules **Andrade**: Mechanical determinism and the notion of the medium; pseudo-elliptic orbits and circular orbits.—Paul **Vuillemin**: The legitimacy of the genera Laverania and Nocardia.—Jules **Baillaud**: The co-ordinates of the galactic pole, deduced from the distribution of the stars in the zone of the Paris astrophotographic catalogue.—M. **Bedeau**: The determination of the specific inductive capacity of mercury vapour. The measurements were made at a temperature of 400° C., under atmospheric pressure, utilising the method described in an earlier communication for air. Mercury vapour shows none of the anomalies proved for steam, ammonia, etc., and its specific inductive capacity is in agreement with 1.00074 deduced from Maxwell's formula.—Jean G. **Popesco**: The variation of the surface tension of mercury in gases. Employing a kinematographic method, the variation of the surface tension of mercury with time of exposure to various gases has been measured. Results are given for air, ammonia, sulphur dioxide, hydrogen, carbon dioxide, and nitrogen. In all cases there is a rapid fall in the surface tension, and the variation is of the same order of magnitude in all the gases, about 5 per cent. reduction in 10 seconds, increasing to about 24 per cent. after 24 hours' exposure.—M. **Lindsay**: The limits of the L absorption of elements Ba, Cs, I, Te, Sb.—R. **de Mallemann**: Rotatory polarisation and molecular orientation.—Pierre **Lambert** and A. **Andant**: An arrangement for depositing films of metal on large surfaces by cathodic projection. The use of greased ground joints is avoided by using a double bell jar. Both jars are exhausted down to about 10 mm., and the evacuation of the inner jar, containing the cathode and object to be silvered, is completed by a Gaede pump.—Ch. **Fabry** and H. **Buisson**: The curve of the distribution of energy in the ultraviolet part of the solar spectrum.—M. **Duffieux**: The mass of the particles which give the spectrum of carbon monoxide. The bands are emitted by particles the masses of which are in the ratio of 16 : 12, and hence are not due to the molecule CO but to its decomposition products, the free atoms of carbon and oxygen.—Paul **Mondain-Monval**: The preparation of ammonium chloride at a low temperature.—A. Ch. **Vournazos**: Mixed complex antimonodobromides. Several complex salts have been isolated, of which the sodium salt $Na(SbBrI_3)$ may be taken as the type.—L. J. **Simon**: The chromic oxidation of the homologues of acetic acid. A comparison of the oxidising effects of the two mixtures, sulphuric acid, chromic acid, and sulphuric acid, silver chromate upon eleven fatty acids. These acids are only partially converted into carbon dioxide and water by the chromic acid mixture, but are completely burnt when silver chromate replaces chromic acid.—Maurice **François** and Louis Gaston **Blanc**: A method of preparing the iodomercurates of the alkaloids in a crystallised condition.—A. **Wahl** and R. **Lantz**: The 2-oxy-1-arylnaphthylamines.—Louis **Longchambon**: The rotatory power of crystals and molecular rotatory power.—René **Abrard**: The presence of *Nummulites variolarius* in the Cresnes, Marines, and Ruel sands and their signification.—P. **Lavialle** and J. **Delacroix**: The wall of the pistil and fruit in the genus Euphorbia.—J. **Athanasiu** and L. **Bull**: The registration of the longitudinal vibrations of muscle during voluntary contraction.—Pierre **Girard**, W. **Mestrezat**, and **Li-Shou-Houa**: A physical view of the selective permeability of living cells for different ions.—Mlle Marthe **Giroud**, Gaston **Giroud**, and L. **Parès**: Experimental researches on the genesis of the hæmoclasic crisis of intensive irradiations.—L. **Panisset**, J. **Verge**, and E. **Grasset**: The fixation-reaction in the diagnosis of tuberculosis in cattle. The Bordet-Gengou method may be applied to the diagnosis of tuberculosis of milch cows.—M. **Denuce**: The treatment of congenital dislocation of the hip.

The New Smoke Abatement Bill.

THE new Government bill to prevent the pollution of the atmosphere by smoke again raises the vexed question of the best means of accomplishing this highly desirable result. That the bill, which merely modifies the existing Act of 1875, will leave matters very much as they are, is, however, the considered opinion of those who framed the recommendations of the Departmental Smoke Abatement Committee appointed by the Ministry of Health.

Two years ago an interim report on the prevention of domestic smoke was prepared at the pressing request of the Minister of Health in view of the large housing schemes in contemplation, only to lie dormant in the department.

It is perhaps not sufficiently realised how much of the dirt and damage in our large industrial centres arises from the domestic hearth. In spite of pious opinions to the contrary, it has been established, from carefully ascertained facts, by two independent observers, that of the 2½ million tons of soot turned into the atmosphere something like four-fifths is emitted from domestic chimneys. But that is not all. This incompletely burnt material, formed to some extent by a process of destructive distillation, such as takes place in gas retorts, is charged with tar, whereby it clings to every object with which it comes into contact. Moreover, the tarry soot is strongly acid with sulphuric acid, and its presence on the mortar and masonry of buildings soon shows itself by their gradual disintegration. The evidence of Sir Frank Baines, the head of H.M. Board of Works, was convincing in this respect, and his specimens and photographs exhibited during the inquiry illustrated in a striking manner the conversion of the calcium carbonate (which cement the siliceous particles of the original stone) into the soluble calcium sulphate and the subsequent crumbling of the surface.

Furnace smoke, on the other hand, owing to its higher temperature of combustion, contains a negligible amount of tar; but consists of fine cinder and grit discharged mechanically by the draught. It is true that it darkens the atmosphere, but it does not adhere to any extent, and much of it is washed away by rain.

To return then to domestic smoke. In a brochure recently published and entitled "The Smokeless City,"[1] Mr. E. D. Simon, a member of the Government Committee and present Lord Mayor of Manchester, and Miss Marion Fitzgerald, his collaborator, have put together the principal facts relating to domestic heating and domestic smoke. The information is drawn partly from the evidence of witnesses who appeared before the committee, partly from the reports of Mr. A. H.

[1] "The Smokeless City," by E. D. Simon and Marion Fitzgerald. Pp. xi+82. London: Longmans, Green and Co., 1922. 1s. 6d.

Barker and Dr. Margaret Fishenden on the efficiency of various forms of grates and kitchen-ranges (already reviewed in these columns), and partly on statistics collected by the Manchester Air Pollution Advisory Board (of which Mr. Simon is chairman) on the cost of washing, a sum estimated at 250,000*l.* a year. The subject is introduced in a preface by Lord Newton, who acted as chairman of the Departmental Committee, and has given time and thought and a sustained and disinterested enthusiasm not often associated in the minds of most people with members of the Upper House. He has even travelled abroad with the sole object of learning how smoke was successfully controlled or prevented in foreign cities.

It is hoped that Lord Newton's pungent remarks on governments—parliamentary and municipal—may be read in the right quarter. He says: "The battle . . . against industrial smoke may be said to have been won in principle, but it is scarcely necessary to warn enthusiasts that there are many parliamentary dangers to be overcome, and that governments are not as a rule particularly zealous in forcing through bills of a non-vote-catching nature."

If the object of the authors was to make out a case against domestic smoke by demonstrating in clear and incisive language, backed by carefully ascertained statistics, its wastefulness and uselessness and the damage it entails, which may be reckoned in millions of pounds annually, the little volume before us may be said to have more than accomplished its purpose. It is now for the public to read the case presented by the authors, take it to heart, and put the conclusions to practical use. The authors have not restricted their remarks to destructive criticism of present methods and appliances for heating and cooking. They have shown a better way. Though they condemn, as all witnesses condemned, the old-fashioned open range, they have described and illustrated modern ranges and discussed their efficiency for varied requirements. They explain in simple language the comparative value of coal, coke, and semi-coke (low-temperature coke) and the relative cost of gas and coal. The book does not profess to be a scientific treatise, and a good deal of recent research on the use of gas for cooking and on the subject of ventilation has been overlooked; but this is no drawback. It is intended for householders, builders, and architects, to whom an appeal based on scientific principles would be incomprehensible and almost certainly unread.

As the new bill excludes all domestic fireplaces and largely ignores the recommendations of the Departmental Committee in regard to new housing construction, it is well that the authors of "The Smokeless City" have saved from the eternal silence of Ministerial pigeon-holes the accumulated and valuable evidence of so many expert witnesses.

Leaving then the subject of domestic smoke, we may consider for a moment the improvements and defects in the new bill. The amendments are few; the qualification of the indefinite term "black" is omitted, and the expression "smoke" includes soot, ash, and grit; the maximum penalty is raised from 5*l.* to 50*l.*, and the person summoned under the Act must show in his defence that he has used "the best practicable means." On the other hand, there is no reference to the supervision of heating arrangements in new private dwellings but only in public buildings; there is no attempt to standardise the system of inspection of factory chimneys, strongly advocated by the representative of the Sanitary Inspectors' Association; no clear definition of the powers of the central authority; no combination of large areas under the County or Borough Councils; no inclusion of new processes emitting noxious vapours; no provision for competent scientific advisors and supervisors appointed by the Ministry of Health to control and report. In short, the position remains very much *in statu quo*, and the prevention of smoke in industrial areas still remains in the incompetent hands of the local authority, without pressure from the central authority.

The only hope for salvation lies in the energetic action of a disinterested sanitary committee and its medical officer. As the two are linked together, and the smoke inspector harnessed to them, and as members of the sanitary committee are usually interested in manufacture and factory chimneys, the prospect of amelioration is not bright. But if such a disinterested sanitary committee, intent on the purification of its atmosphere, existed, it would reduce boiler smoke to a negligible amount (and the greater part of the factory smoke comes from boilers); it would have a building to exhibit the best appliances for domestic heating and cooking; afford details of the cost of installation and efficiency; it would promote classes for stokers, and appoint an expert, scientifically trained, and well-paid inspector. Such an ideal committee would within a short period render the atmosphere comparable with that of the clean industrial centres of France or Germany.

J. B. COHEN.

The Earth's Structure and its Evolution.

Earth Evolution and its Facial Expression. By Prof. W. H. Hobbs. Pp. xviii+178. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1922.) 15*s.* net.

THIS volume is intended to present to the non-technical reader the author's conclusions on the form and structure of the earth's crust. The

contents may be summarised as follows. The first chapter deals with some theories of world formation, Laplace's nebular hypothesis being a special object of attack. The second chapter discusses the nature of the earth's interior, after which four chapters relate to the facts and problems connected with volcanic lava. A broader viewpoint is returned to in chapter 7, which treats of the changes of figure through which the earth has passed; this subject is further developed in the following five chapters, the titles of which refer to the present regions of rapid change, the contrasted aspects of the earth's face, the migrational movements of the earth's surface, the patterns of the "facial wrinkles," and the design of the fracture marquetry. The bearing of the composition of lavas on the question of earth physiognomy is then dealt with, and the final (fourteenth) chapter again reviews the theories of the earth. The author gives a list of references at the end of each chapter to works and papers on the subject of the chapter, but no general index of names or subjects is provided, an omission which should be supplied if a second edition is called for.

Despite the somewhat terrifying vocabulary of the geologist, the book contrives to be interesting, and one of its most commendable features is its wealth of illustration, by diagrams, maps, and photographs. The discussion is of a less broad and comprehensive character than the title would lead one to expect, the balance of the book being rather upset by the prominence given to the vulcanological topics in which the author is specially interested. In themselves, however, these chapters contain some of the most novel and interesting parts of the book.

A more serious criticism than that of the title is that the author makes no mention of much important recent work bearing on his subject, as, for example, when dealing with general theories of earth formation, where one is surprised to find nothing about Jeans's cosmogonic researches. The author is particularly concerned to overthrow the notion, based on observations of volcanic lava, that the earth's interior is molten, only the crust being solid. This view has been generally abandoned by geophysicists, on the ground of seismological and other evidence which the author describes It has, however, long been historically connected with Laplace's nebular hypothesis, though the latter is of much later date, and the two theories are not necessarily bound up together.

The author gives much prominence to Chamberlin's arguments against Laplace's theory, and regards them as destroying the last support of the hypothesis of a molten interior, and as necessitating a fundamental revision of geological theories Nevertheless, strong as are Chamberlin's arguments—based on considerations of angular momentum—they have not convinced so great an authority on cosmogony as Jeans, that Laplace's nebular theory must be finally condemned, though Jeans has propounded a modified form of the theory to explain the origin of the solar system, which is of a very special type among celestial objects; in this theory the planets are supposed to have been separated from the sun, when the latter was much more diffused than now, by the passage of another star at a distance comparable with the sun's diameter at the time. This theory thus preserves the feature of Laplace's hypothesis which seems specially in disfavour with the author, viz. that the earth has cooled down from a diffuse gaseous state. The author himself advocates the planetesimal hypothesis, *i.e.* that the earth originated as a solid body by the aggregation of meteoritic material. However great the claims of this view may be regarded, our present knowledge, or rather ignorance, of the effect of pressure upon hot bodies certainly does not permit us to preclude the other view, that the interior of a large gaseous body might become solid under the influence of the pressure of the upper layers, before or at the same time as the formation of a solid crust.

Another outstanding omission to refer to recent work bearing on the subject relates to Wegener's theory of moving continental masses, now so much discussed by continental geologists. By many interesting diagrams the author shows the situation of the regions of present rapid change and great folding, and discusses Suess's theory that this folding is in general the result of overthrust of one land mass over another. Professor Hobbs's view is that mountains are raised as a result of underthrusts going out from areas of subsidence, generally the ocean areas. These thrusts are supposed due to shrinkage of the strata under the oceans, though no attempt is made to put the hypothesis on a quantitative basis. This, however, is perhaps scarcely feasible as yet, and Wegener's theory, which attributes the thrusts to the resistance of the heavier substrata to the motion of the land masses as wholes, has likewise many points of difficulty about it.

The author's theory of the origin of pockets of molten lava is one of the most interesting parts of the book. The rigidity of the earth is maintained under conditions of internal temperature which are sufficiently high, even relatively near the surface, for at least the aqueous fusion of rock. This rigidity is due to compression by the overlying load, which greatly raises the fusion point. It would therefore seem as if molten matter could exist only in places where the weight of the upper layers has been wholly or partly removed. This is supposed to occur by the folding of

strong upper layers of rock into domed or arched forms, relieving the pressure beneath, at least for a time. This view differs widely from the one commonly held, viz. that the underground chambers of lava represent intrusions through the strata on which they rest, and that the pressure of the lava has itself elevated the roof of the chamber. The author ably supports his thesis by many different lines of evidence.

Textile Technology.

Textiles. By Prof. A. F. Barker. With chapters on The Mercerized and Artificial Fibres, and the Dyeing of Textile Materials, by W. M. Gardner; Silk Throwing and Spinning, by R. Snow; The Cotton Industry, by W. H. Cook; The Linen Industry, by F. Bradbury. (Westminster Series.) Revised edition. Pp xii+386. (London: Constable and Co., Ltd., 1922.) 15*s*.

OF the great trinity of human life's essential needs – food, shelter, and clothing—practically all the articles of clothing, as well as a considerable number of articles for improving the shelter, are derived from textiles. The provision of these and other articles has led to the development of the great textile industries. These industries together form the only serious rival to agriculture for chief place among the industries of the United Kingdom, while they rank supreme in their contribution to the country's exports, of which no less than some 40 per cent. are textiles.

It might be expected, therefore, that a large number of people would be interested either as producers or consumers in such a work as the present, which aims at giving in brief compass an outline of the textile industries in their historical, technical, industrial, and commercial aspects. The book opens with an historical introduction, there follow descriptions of the raw materials and their production, and of the principles and processes of spinning, weaving, designing, and finishing. Later chapters deal with the separate industries in turn, namely, the woollen, worsted, cotton, silk, linen, dress goods, etc., and the carpet industries. On the whole the purpose of the book is successfully achieved. The author rightly emphasises the fact that it is the article finally produced which determines the raw material employed and the processes through which this passes. It is for this reason that he deals first with the general principles of spinning and then with the various preparatory processes, which were developed later chronologically for the purpose of presenting the raw material to the spinning machines in a convenient form. The chapter on spinning, in which are described the modern machines and their relation to the old methods, is the best chapter in the book; the account of the preparatory processes is somewhat scanty, rather disjointed, and occasionally inaccurate. Improvements might be made in certain other directions. Thus, the descriptions of machines sometimes suffer from the absence of explanation of some of the technical terms used; while the replacement of a number of the illustrative photographs by line drawings would add considerably to the value of the book.

It is to be regretted that there is no uniformity of plan in dealing with the separate industries; each special contributor writes from his own particular point of view, with the result that a recasting of their work would be necessary to preserve the unity of the whole. None of these special chapters compares favourably with Prof. Barker's own contributions in general treatment and the selection of material; and in too many instances the statistics and other information, having remained unchanged from the 1910 edition, are now so out-of-date as to be misleading.

In spite of its deficiencies, however, this work remains probably the best in English affording a general introduction to the study of textile technology, and as such it is to be commended.

Highway Engineering.

Les Chaussées modernes. Par Prof. P. Le Gavrian. (Encyclopédie du Génie Civil et des Travaux Publics.) Pp. 431. (Paris: J.-B. Baillière et Fils, 1922.) 40 francs.

THE publication of this text-book marks another step forward in the evolution of one of the most recent developments of engineering and is therefore to be welcomed. Road engineering in its modern form may be said to be contemporaneous with the motor car, the advent of which has again brought a large portion of the national transport on to the roads after an eclipse which lasted from the decline of the stage coach, or even the Roman period, until the introduction of the internal-combustion engine for road vehicles.

The problem of constructing roads to suit modern traffic has probably been best met in Great Britain, but the task fell to busy men, the engineers to the local government authorities, who have had many other pressing and difficult problems to deal with during the same time. Consequently, the practice which has been developed, although well described in the periodical literature, has not been codified or reduced to the form of text-books, although two small publications by Mr. H. P. Boulnois and Mr. F. Wood have to a certain extent met the want.

France has, however, already established a Chair of Highway Engineering, the first occupant of which is

the author of this book, while the project is still under discussion in this country. The chair being established, the need of a text-book has been immediately felt and M. Gavrian has met the want by his excellent book.

The first point that strikes one is that the author does not assume previous knowledge of the subject but begins by a discussion of the conditions to be satisfied and the materials which are available, but it is obvious that he expects the student to have a working acquaintance with chemistry, physics and elementary engineering.

The consideration of the action of vehicles on the road surface and *vice versa* is clear and concise; it deserves to be well considered by every one who is interested in the road problem as there is much confusion and uncertainty on this aspect of the problem.

Another section worthy of every commendation is the chapter devoted to definitions and nomenclature. The application of the same or similar names to different substances and compounds in England, France and America has led and can only lead to misapprehensions and failure to take advantage of experience gained in other countries. It is gratifying to note that English nomenclature meets with his approval, and until a standard international nomenclature is established his summary of the differences will be most valuable. The second and third chapters are devoted to a description of the production and testing of tars, pitches and other binding materials, the latter of which is probably worthy of more careful attention than is always given to it, since some failures have undoubtedly been due to materials differing in composition and properties from those employed successfully elsewhere.

A discussion of the relative usefulness and suitability of various rocks and slags in combination with different binders would have been useful as a separate section, while the binder used in Rocmac deserves more space as it has advantages in certain situations probably not possessed in the same degree by other materials.

Considerable attention is given to the manner in which pot holes are formed and the obscure phenomena known as corrugation of road surfaces. No conclusion is put forward with regard to the latter, but the need for careful research is urged. It is probably not a simple problem and will resist resolution for some time as the related problem of the corrugation of steel rails subjected to electric traction has done although the conditions can be much more exactly determined in the latter case.

M. Gavrian has collected a considerable quantity of data on the tractive effort required on different types of road surface and for different types of tyres; this is all to the good as the publication of authoritative figures should do much to reconcile transport owners to the high cost of modern roads by showing that there is reduction in cost in another direction. The destructive effect of certain kinds of tyre is also well brought out and may help towards their elimination if it brings home to the vehicle owner that any slight advantage he may gain individually has to be paid for eventually in greater expenditure on the road itself.

A standard English text-book of this type would be of great assistance to the student not only of highway engineering but of general engineering also, as the subject is too often neglected.

Radio-Communication.

(1) *Die drahtlose Telegraphie und Telephonie.* Bearbeitet von Dr. P. Lertes. (Wissenschaftliche Forschungsberichte. Naturwissenschaftliche Reihe. Herausgegeben von Dr. R. Ed. Liesegang. Band IV.) Pp. xi+152. (Dresden und Leipzig: T. Steinkopff, 1922.) 4s.

(2) *Marine Wireless Pocket Book for the Practical Operator and Student.* By W. H. Marchant. Pp. vii+180. (London: Sir I. Pitman and Sons, Ltd., 1922.) 6s. net.

(3) *Continuous Wave Wireless Telegraphy. A Non-Mathematical Introduction to the Subject of Wireless Telegraphy from the Engineer's Point of View.* By B. E. G. Mittell. (Pitman's Technical Primer Series.) Pp. xvi+114. (London: Sir Isaac Pitman and Sons, Ltd., 1922.) 2s. 6d. net.

THE development of the art of radio-communication has been so rapid that much of the apparatus described in technical books on the subject is either obsolete or is very little used. Its inclusion, however, may be justified on the ground that it is wanted by students for examinational purposes. As the number of books on the subject is large and is rapidly increasing, the expert who reads them all will naturally weary of going over the same ground so often.

(1) Dr. Lertes's book will be of value as a work of reference. The descriptions are much too brief to be followed by any one who is not thoroughly familiar with the subject. A wealth of references are given which will be useful to any one who is making a special research on some branch of the subject. It would, however, be a help to the reader if the references were subdivided under various headings such as mathematical, physical, technical, and commercial. The ground covered is very wide and an account of the Johnsen and Rahbek electrostatic relay is included.

(2) This pocket book is intended principally for the

narine radio-telegraphist. Detailed instructions are iven as to the methods of adjusting the various tandard Marconi sets. Descriptions are also given f the apparatus of the Telefunken and Radio-Communication Co. The diagrams are very clear and the ables, rules, instructions, etc., included have been well elected.

(3) As the bulk of the world's radio-communication s carried on by continuous wave (C.W.) systems, t is natural that there should be a demand for elementary but accurate descriptions of these systems. The number of C.W. arc stations now exceeds a thousand, and more than 10,000 kilowatts have been installed or their operation. There are also many high requency and valve generator stations. As space s limited in this booklet, some of the descriptions of mportant methods are too brief to be of much help o the reader, and there are notable omissions. The chapters on the advance of the C.W. system and on he Poulsen arc are instructive and contain novel natter. We can commend the book.

Plant Morphology and Physiology.

Practical Plant Biology: A Course of Elementary Lectures on the General Morphology and Physiology of Plants. By Prof. H. H. Dixon. Pp. xi+291. (London: Longmans, Green and Co., 1922.) 6s.

A TEXT-BOOK by such an experienced teacher as Prof. H. H. Dixon is very welcome. To judge from the introduction, this book represents in condensed form the series of lectures which the author has found most suitable for the introduction of his subject to a class in which medical students predominate. At the end of each lecture brief notes are added as to the scope of the practical work to be carried out in conjunction with the course. Each lecture occupies on the average about eight pages, and in the thirty lectures a wide series of types are covered, from unicellular forms to the flowering plant. Considerable physiological work is included, and the subjects of nuclear division, heredity, and evolution occupy the last three lectures. The treatment is therefore of necessity much condensed, and an elementary student would find it difficult to use the book except under guidance.

Three salient features in the book have impressed the present reviewer. The first is the interest and charm with which the author's style and personality invests the subjects of the elementary course. It is clear that each time Prof. Dixon renews his acquaintance with these familiar plants, his class will find him filled with the enthusiasm of a first encounter. The student cannot forget that he is studying living plants, even when examined in the remote region of a "microscopic field." With the aid of a "ghost micrometer," an instrument Prof. Dixon demonstrated to Section K of the British Association for the Advancement of Science at Edinburgh last year, comparative data as to size, rate of movement, etc., are always kept before the student. The brief instructions given on p. 74 for practical work with Spirogyra provide an excellent example of how to make a student realise that Spirogyra is a living object in a three-dimensional world, and not a design transferred from the plane of the microscopic image to the plane of the paper. The second striking point is that the author has found it advisable to build up a knowledge of the plant by progress from the simpler unicellular forms to the more complex vascular plants. The initial difficulty of the unfamiliarity of the plant forms thus first introduced to the student is grappled with most successfully, and very interesting use is made of the opportunity thus provided, at an early stage of the course, of indicating the great practical and human significance of biological studies. On the other hand, this method of approach appears to make the treatment of plant physiology more disconnected and less experimental. Photosynthesis appears fairly early in the course, but the experimental treatment at this stage does not encourage any effort to associate the process with gain in dry weight and in carbon content. Respiration is discussed first as an anaerobic process with yeast, and later is treated more generally under Chlamydomonas. While some general questions as to the water relations of the cell appear in Lecture II., root pressure and translocation, hinted at in Lecture XIX. on the fern, are not fully treated until Lecture XXV.

Coming to the third point of interest, as might be anticipated from the author, a much wider use is made of relatively complex data from physics and chemistry than is usual in an elementary botanical text-book. If botany is to progress this seems to be an essential development, even if it implies ultimately a recognition that elementary botany courses need building upon the physics and chemistry of the final years of the graduate science course! Lecture II. introduces us to diffusion and osmosis, Lecture III. to phenomena of the colloid state, Lecture IV. to enzyme action and surface phenomena in heterogeneous systems. This pace is rather sweeping and makes great demands upon the student. It is probably also inevitable that as botanists venture into these paths, the pioneers will stumble occasionally in their unfamiliar surroundings. The attempt to define the difference between a gel and a sol on p. 22 appears to be a case in point. The explanation here given of the structure of a gel would render the phenomena of diffusion in

such gels entirely unintelligible, and the experiment illustrating the retention of congo red by a gelatin gel must receive quite another explanation than that given to it.

The Development of Vertebrates.

Traité d'embryologie des vertébrés. Par Prof. A. Brachet Pp xvi+602 (Paris: Masson et Cie, 1921) 60 francs net.

FOR a remarkably clear and well-illustrated account of the development of the vertebrates the student could not do better than turn to this text book from the pen of the distinguished professor of the University of Brussels The information given is thoroughly up-to-date, the conclusions for the most part convincingly supported by an abundance of facts marshalled with great skill While the author does not hesitate to discuss controversial questions, yet this treatise is strikingly free from prejudice, and none the less interesting because it deals for the most part with matters of fact. We find none of the fantastic phylogenetic interpretations of developmental stages according to the recapitulation theory which disfigure so many general text-books of embryology

Naturally, in a single volume of some 600 pages, the whole range of vertebrate embryology cannot be covered in detail, and it is the early stages and germ-layer formation that receive particular attention We know of no text-book in French or English with such a lucid account of these complex processes in the vertebrates By skilful selection and the omission of unimportant detail Prof Brachet also provides good descriptions of the development of the chief organs The development of the cranial nerves for instance, is particularly well presented

There are some points on which the author is not convincing, and on which his conclusions might, we think, be revised and modified In the account of the mesoblastic somites of the head, like so many other embryologists, he uncritically adopts van Wijke's scheme of enumeration, which inevitably leads to confusion in the region of the hyoid arch, instead of Balfour's system. We are unable to understand his reluctance to admit that in vertebrates above Amphioxus there are still traces of the formation of mesoderm from enterocoelic pouches, and we consider that he attaches too much importance to what he terms acrogenesis, cephalogenesis and notogenesis, a distinction which seems somewhat artificial and founded on certain specialisations of growth in the embryos of higher forms. Nevertheless, Prof Brachet's volume is an excellent treatise, and will be heartily welcomed by students and teachers of embryology.

Our Bookshelf.

The Principle of Relativity Original Papers By A. Einstein and H Minkowski Translated into English by M. N. Saha and S N Bose With a Historical Introduction by Prof P C. Mahalanobis Pp xxiii+186. (Calcutta: University of Calcutta, 1920.)

THE book under review begins with an interesting historical account of the experiments dealing with the elucidation of the æther-idea in physics, and we are led through the work of Michelson and Morley, Lorentz and others to a brief account of Einstein's theory of relativity and some of the results obtained with its aid. The second section reproduces Einstein's original paper "On the Electrodynamics of Moving Bodies" (*Annalen der Physik*, 1905), and this is followed by a short note on Albrecht (!) Einstein and the various phases of his scientific activity. The next section on the "Principle of Relativity" is apparently a translation of Minkowski's paper on "The Fundamental Equations for the Electromagnetic Processes in Moving Bodies" (*Gottinger Nachrichten*, 1908), though no reference is given, and the title is omitted. An appendix to this is given, and it concludes with the well-known lecture of Minkowski on "Space and Time," delivered to the German Naturforscherversammlung at Cologne (1908), and published in the *Physikalische Zeitschrift* (1909) and in "Das Relativitatsprinzip," a collection of papers by Lorentz, Einstein, and Minkowski (Teubner, 1913) The sixth section of the book consists of Einstein's monumental work on the "General Theory of Relativity and Gravitation" (*Annalen der Physik*, 1916), and the concluding section brings a number of explanatory notes, mostly mathematical, on special points

The translation cannot be called a good one In a work of this kind we expect a fairly literal translation, but in the present book there are numerous errors in translation, and the choice of English equivalents for German words is frequently unfortunate In many instances the mathematics is faultily reproduced. The numbering of the pages is not continuous, but recommences at the beginning of section 4, and the omission of the footnotes from the originals is regrettable Provided it is studied with care, the translation will nevertheless be of service to those who are unfamiliar with German, and wish to grapple with the pioneer works on this subject, some of which are rather inaccessible

A Little Book on Water Supply. By Dr William Garnett Pp. xv+144 (Cambridge At the University Press, 1922) 6s 6d net

"This little book when in manuscript was condemned by a very high authority on educational publications, for it did not enable the reader to prepare for any specific examinations" So the preface begins. But was not the very high authority anxious to be kind? We, too, are inclined to condemn the little book as an educational work, not because it is useless for examinations, but because it lacks a coherent plan

There is no attempt to group the portions of letterpress into chapters. General statements are sand-

wiched between local descriptions, thus "Aqueducts" are treated between "Storm Waters" and "The Water Supply of New York", "Watersheds and Water-partings," with a long description and full-page illustration of the Rhone Glacier, appears between engineering details of the water-works of Glasgow and of Liverpool. And between "The Birmingham Water Supply" and "Proposals to supply London from Wales" there is an account of the Nile storage at "Assouan" in a paragraph devoted to "Other Famous Dams."

Apart from the absence of arrangement, the book fails in saying next to nothing of the rainfall of the country and its fluctuations, data for which in immense abundance are available, nothing of the system of legislation by which water supplies are allocated save for scraps in relation to individual schemes. An appendix gives an account of the theory of cyclones put forward by Prof. Bjerknes, but there is nothing as to the distribution of rainfall in the actual cyclones which traverse the British Isles.

As a scrap-book of useful and often entertaining information on the supply of water to modern London and ancient Jerusalem the book will give pleasure to many readers, and the facts as to other cities, ancient and modern, are accurate wherever we have tested them, though not always up to date. Our sole complaint is that a scrap-book should be put forward as an educational work, for we hold that continuity of plan, clearness of arrangement, and simplicity of statement are essential for any such book, and these we do not find. We repeat that large parts of the book are excellent, and every Londoner would do well to read those which refer to the Metropolitan Water Board.

H. R. M.

Étude géométrique des transformations birationnelles et des courbes planes. Par Henri Malet. Pp. viii+261. (Paris: Gauthier-Villars et Cie, 1921.) 32 francs net.

ORTHODOX elementary geometry deals principally with the metrical properties of space, based on Euclid's axioms. In the modern developments of geometry the metrical properties are a secondary consideration. The study of ordered aggregates of spatial elements, such as points, lines and planes, became a powerful weapon in the hands of the geometers of the last few generations, and one of the most useful forms of this study is the method of transformations and correspondences. M. Malet sets himself the task of presenting the fundamental ideas of correspondences, leading up to the generalised type which forms the title of his book. As is natural he offers first a careful study of homographic correspondences of points on straight lines, then the *method* of projection, coming finally to birational transformations. His method is purely geometrical.

The theory is applied to the type of plane curves called algebraic, defined by the author in the sense that one and only one algebraic curve can be made to pass through a number of given points in a plane, these points being independent: he examines carefully the meaning of independence.

Attention is directed to the remarkable fact that many of the most important contributions to modern geometry have been made by Frenchmen; M. Malet claims that this is due to "ces qualités de clarté et de précision qui furent toujours l'appanage de notre race."

S. B.

A Manual of Indian Timbers: An Account of the Growth, Distribution, and Uses of the Trees and Shrubs of India and Ceylon, with Descriptions of their Wood-Structure. By J. S. Gamble. Reprint of second edition with some additions and corrections. Pp. xxvi+868+20 plates. (London: Sampson Low, Marston and Co., Ltd., 1922.) 3*l.* 3*s.* net.

THE Empire Timber Exhibition, held in London in July 1920, was remarkable for the number of beautiful woods which were displayed in the India section. It was difficult to understand why most of these valuable timbers were either unknown or not appreciated in the European market. Most people in this country believed that teak was the only timber of importance produced in India, and were surprised to see the variety of species that were made up into furniture, panelling, parquet flooring, and a host of miscellaneous articles, ranging from fishing-rods to scientific instruments. The cause of the neglect of Indian woods may be put down to lack of business methods on the part of the Government, which controlled the great bulk of the forests. This supineness is now a matter of the past, and efficient measures have been taken to make known in England the wealth of timbers available.[1]

The publication of a reprint of Gamble's "Manual of Indian Timbers," which has been for many years out of print, is a step in the right direction. To those who are unacquainted with this splendid book, we may direct attention to the accurate mass of information which it contains on the timbers and forest trees of India, Burma, and Ceylon. About 1500 species are described; and their uses and qualities are pointed out.

A Guide to the Identification of our more Useful Timbers: Being a Manual for the Use of Students of Forestry. By Herbert Stone. Pp. viii+52+3 plates. (Cambridge: At the University Press, 1920.) Price 7*s.* 6*d.* net.

THE distinctive characters of the commoner kinds of timber are well described in this brief manual, which should prove useful in teaching students. Thirty-one broad-leaved trees and ten conifers are included, all of which, except four: teak and three kinds of mahogany, are cultivated in this country. It is assumed that the student has sufficient knowledge of the elementary structure of wood to follow the descriptions. There are three plates. Certain slight errors in nomenclature should be corrected in the next edition. The term "deciduous oaks" is chosen to designate the two British species. This is not a distinctive name, as it does not include in this manual the American white oak and red oak, which are equally deciduous. *Ulmus effusa* (p. 18) is not a "bad" species, as alleged, but is a name applied to a distinct elm, not native to Britain, which is perhaps more correctly called by the prior name of *U. pedunculata*.

[1] See "Indian Trade Enquiry Reports on Timber and Paper Materials," published in 1921 by the Imperial Institute, where possible uses in this country for thirteen different woods, other than teak, are suggested.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Influence of Science.

THE ingenious letter under the above heading, on page 180 of NATURE of August 5, by that industrious astronomer of Stonyhurst College, Father Cortie, S.J., seems to require some brief notice because of the singular character of the statements made in it. We are asked to believe that Copernicus's "heliocentric doctrine was freely taught, even in ecclesiastical colleges, until Galileo interested himself as a champion of the system" in spite of the admission that after this "truculent and hot-headed controversialist" had endeavoured to get the Church to realise that the doctrine was not really antagonistic to Scripture when reasonably interpreted, and after the offended Pope had brought the matter before the Holy Office, that authority determined that "the Copernican system was false and absurd philosophically." And we are also asked to believe that the outcome was merely that Galileo had as a penance "to recite certain prayers, and was sent to a beautiful villa at Arcetri", the implication being that there was really no punishment, and that there was no call for anxiety or distress on the part of either him or his daughter throughout the proceedings.

Yet some of us have learnt from extant documents that Galileo was made to recant, to abjure and curse the theory of the earth's motion, and to promise to denounce to the Inquisitor any one suspected of similar heresy.

Some rather definite pressure must have been brought to bear upon the old man in order to secure this damning retractation—a retractation which the younger and more energetic Bruno a few years previously had contumaciously refused to make. Perhaps, however, it may be contended that in Bruno's case also the Cardinals "proceeded with all the gentleness and moderation which were compatible with judicial forms!" If so, it is a comfort to us scientific heretics of to-day that judicial forms have by this time lost some of their virulence and the Holy Office some of its power. The flail of orthodoxy is still wielded in high places, by searchers out of scientific heresy; but the penalties inflicted are no longer ecclesiastical, and—*pace* Father Cortie—are less severe.

On second thoughts it occurs to me that the letter may be intended humorously, in preparation for the suggestion that the Church and the Aristotelian professors had some inkling or precognition of the theory of relativity. Father Cortie summarises "the only proofs that were brought forward" for the heliocentric doctrine; and doubtless the court concluded, as modern self-elected authorities do in an analogous case, that "there is no evidence" for any modification of conservative tradition.

OLIVER LODGE.

Action of Cutting Tools.

IN NATURE of July 22, p. 118, there is an interesting description by Prof. E. G. Coker of experiments in which the strains and stresses of a transparent material (celluloid) in the neighbourhood of the edge of a cutting tool were made apparent by polarised light.

It ought to be noticed that the word "cutting" as applied to tools used for metal work (and hard substances), though generally in use, is incorrect, the actual action of such tools being to cause shearing.

Cutting and shearing differ in that in the former the part removed by the tool is merely bent, while in the latter it is at the moment of formation exposed to

FIG. 1.—Cutting action of knife.

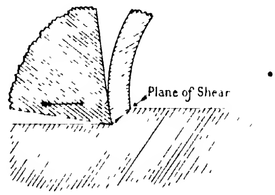

FIG. 2.—Shearing action of tool.

intense local shearing sufficient to cause permanent set or fracture throughout its whole thickness. This is illustrated in Figs. 1 and 2.

In connexion with this subject I may refer to a paper of my own (Proc. Roy. Soc., 1882), which, so far as I know, is the only place where the distinction has been made. There are very few tools and very few materials which lend themselves to true "cutting" (*e.g.* thin-bladed tools and soft substances like animal tissues), and in any attempt to "cut" hard materials the tool is soon brought up by the frictional grip of

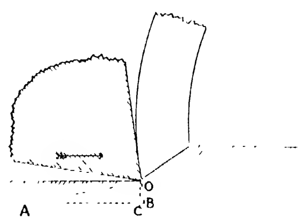

FIG. 3.—OA normal force on face of tool; BO frictional force on face of tool; OC component of OA tending to make the tool "dig"; CO component of BO tending to make the tool lift.

the material on the blade. In tools for hard materials (*i.e.* shearing tools) the friction of the shearing on the face of the tool is the chief factor in the determination of the angle at which the tool face should be presented to the work. Any angle will cause the requisite shear, but unless the friction on the face balances the inward component of the force due to its slope, the tool will either tend to "dig" or to retreat from the material being operated on (see Fig. 3).

Thus for soft copper or aluminium, for example, where the coefficient of friction is large, the angle should be more acute than for brass, where the friction is much smaller.

Rudbeckia and Aquilegia.

When recently (July) collecting Eocene fossils in the vicinity of Roan creek, Colorado, I saw for the first time the singular composite *Rudbeckia montana* Gray in life. It abounds in the valleys and gulches, occupying similar positions to those in which one finds *R. laciniata* on the eastern side of the range. The latter, so far as I could ascertain, is absent from the region of *R. montana*, though it occurs in the south-western part of Colorado. The striking feature of *R. montana* is the total absence of rays. The large conical or cylindrical discs appear very black, slightly yellow from pollen when in flower. The involucral bracts are coarse and pointed, surrounding the base of the disc and diverging at various angles. The whole effect is most peculiar and unusual. Rayless Compositae are known in various genera, and occasionally occur as mutations in normally rayed genera. The ancestor of *R. montana* was presumably rayed, but losing its rays through a germinal modification, how did it manage to survive and flourish to the exclusion of the rayed form?

On July 21 I took particular occasion to watch a large group of *R. montana* on Dry creek, a tributary of Roan creek. The plants appeared just as attractive to bees as the rayed species. They were being visited by great numbers of worker Bombus, the majority *B. rufocinctus phaceliae* Ckll., but there were also many *B. edwardsii bifarius* Cresson. Other bees were fewer, but I collected females of *Megachile pugnata*, Say, *M. grindeliarum* Ckll. and *Halictus trizonatus* Cresson. There were also two species of plant-bugs, *Lygaeus reclivatus*, Say, and *Lygus pratensis* L. Thus it seems certain that the loss of the rays has not interfered at all with cross-pollination by bees.

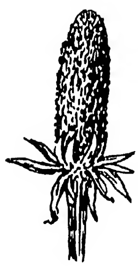

Fig. 1.—*Rudbeckia montana*, Gray. ½ natural size.

On the high mesa, between Roan creek and Salt Wash, in the aspen groves, I first saw the white-flowered sub-species of the Columbine, *Aquilegia caerulea* James. The large white flowers, with long spurs (up to 90 mm.), dotted among the green shrubbery, were truly magnificent. One got the impression of a perfectly distinct species; but some of the flowers were suffused with blush, and rarely one found a genuine *A. caerulea* with blue sepals. The flowers certainly averaged larger than those of *caerulea*, but the spurs were long enough for Tidestrom's *pinetorum*, which seems possibly to be a habitat-form.

The locality on the Roan mountains is in the midst of a Canadian zone flora, with no pines, the only conifer being *Pseudotsuga mucronata*, which is abundant. *Pinus edulis* and *Sabina* occur on the slopes lower down. The underlying geological formation is the Green river Eocene. The white (*albiflora* Gray) sub-species of *A. caerulea* may well have arisen by mutation from the blue-sepalled type, but how did it manage to supplant it? It cannot be a matter of the direct effects of the environment, since genuine *caerulea* grows rarely in the same localities. Both forms are visited by Lepidoptera, and there is no reason for supposing that *caerulea* is specially favoured by butterflies, *albiflora* by moths. In the locality of *albiflora*, as we found it, long-tongued moths must be very rare, but long-tongued butterflies (especially Papilio) abound.

These cases of Rudbeckia and Aquilegia are difficult to explain. Is it possible that, while there is no direct influence of the environment on the characters, there is something in the soil (the shales being rich in peculiar organic products) which has affected the germ-plasm of the plants, bringing about a selective elimination of certain qualities?

The Rat and its Repression.

The valuable contributions on rat repression by Lord Aberconway and Lieut. Alfred E. Moore, which have appeared in the columns of Nature, may, I venture to think, be usefully amplified by some reference to one of Britain's paramount industries: shipping, considered in the light of the rat menace.

Undoubtedly, rats represent a serious problem to the shipping industry, and I only suggest some possibilities that occur to me in the hope that others more competent may be induced to table something more valuable. Among the avenues to be explored are:—

(*a*) The possibility of an international agreement in regard to ship fumigation and disinfection, having special regard to ships arriving at British Empire ports.

(*b*) The possibility of stimulating invention in regard to ship-proofing, *e.g.* anchor chains, mooring ropes, gangways, and all shore connexions are avenues of minute possibility when one is considering rat invasion.

(*c*) The possibility of stimulating research into the most effective means of destroying rats aboard ship by means of fumigation, electricity, traps, raticides, etc.

(*d*) The possibility of creating a national board composed of the representatives of port authorities, ship owners, authorities on rat repression, and ship store superintendents, and of providing in connexion with such national maritime board suitable laboratories for testing and research.

(*e*) The possibilities of asbestos-concrete plus barium carbonate as a light and at the same time poisonous covering in the place of wood where its use would not be inconvenient.

It is doubtful if man has a more cunning foe than the rat, and in view of the fact that the vermin is ever increasing, and the rat's adaptability when it is called upon to vanquish obstacles to its depredations, it seems to me well worth our while to concentrate upon effective measures to counter the activities of our enemy.

The Spectrum of Helium in the Extreme Ultra-Violet.

Mr. Fricke showed (*Phil. Mag.* 41, May 1921) that in the extreme ultra-violet the arc spectrum of helium probably contained but one line with a wave-length near 585 Å.U.

I have recently attacked the subject again using a vacuum spectroscope so arranged that a good vacuum could be maintained in the body of the apparatus while the discharge tube contained helium at a pressure of about a millimetre. No window was employed, the success of the device depending on the use of a very short and narrow slit and upon the suitable application of a powerful pump.

With a continuous current the line at 584.4 is of very great strength, and is accompanied by three new lines at 537.1, 522.3, and 515.7 whose intensities decrease with their wave-length and in a manner strongly suggesting a series relation. Luckily the

first three members appear in the second order spectrum, a comparison with the hydrogen line 1215·68 and with the three following lines of the same series is therefore possible, with the result that the wave-lengths are probably correct to one or two tenths of a unit.

The spacing of these four helium lines on the frequency scale is of great interest and importance, for it is found to be identical with the spacing of the first four lines in the singlet principal series. It may be stated, therefore, with considerable certainty that the line 584 forms the first member of a principal series, which, according to the notation of Prof. Fowler, is to be represented by $oS-mP$.

Besides this series there is a single line at 600·5 ± 0·3 of a feeble and diffuse character; its origin is not entirely above suspicion. In the extreme ultra-violet the arc spectrum of helium appears to contain no lines in addition to those just mentioned.

The relation between the accepted values of the resonance and ionisation potentials in helium and the wave-lengths of these new lines is rather puzzling. The ionisation potential should certainly correspond to the limit of the $oS-mP$ series; now this limit can be accurately calculated, it corresponds to 24·5 volts, but the experimental value is 25·3 volts. This is the chief difficulty, but it is not the only one, for the agreement between the wave-lengths of the individual spectrum lines and the values of the resonance potentials as determined by Franck and Knipping is not satisfactory. A correction of about −0·8 volt, if applied to all the potential measurements, will bring the two sets of data into fair agreement, but at the expense of the first resonance potential which is left without any corresponding line in the spectrum.

The matter should be of some interest to those who are struggling with the model of the helium atom.

Transcription of Russian Names.

With regard to the recent correspondence in Nature on the transcription of Russian names, may I direct attention to the fact that the Russian Academy of Sciences adopted a system of transliteration many years ago, and a note by Prof. J. W. Gregory giving the new rules appeared in Nature on May 14, 1908, p. 42. In all the publications of the Academy the Latin transcription of Russian names is given in accordance with this system.

Since, in the event of Russia adopting the Latin alphabet, the Academy of Sciences, as the highest authority of the country, will be called upon to formulate the rules, I think it would be advisable for all countries to conform to the rules already set forth by this Institution.

It is needless to say that at present Russian transcription is in a very confused state, the name of the same author being frequently given in different ways (*e.g.* Cholodkovsky, Kholodkovsky; Ivanov, Iwanow, Iwanoff).

Sense of Smell in Birds.

The observations with regard to the olfactory sense of vultures recounted by Mr. C. B. Williams (Nature, July 29, p. 149) are at variance with those of hunters and field naturalists and the experiments of Audubon, Bachman, and Darwin (see Darwin's "Journal of Researches, Voyage of H.M.S. *Beagle*"). From *a priori* reasons it could be argued that birds as a whole depend mainly on sight, and no one would be inclined to deny an obvious fact when it is emphasised by morphological modification. Ducks and geese and other birds which feed for long periods on land and marsh certainly have good powers of smell, but in the majority the sense is feebly or not at all exercised. The conclusions of Mr. Abel Chapman given on pages 241 and 423 of his "Savage Sudan" (1921), that with few exceptions birds and certainly that eagles and vultures possess no sense of smell, deserve attention, for he is a wildfowler with a long experience. He has told me, among many interesting observations which prove the fact, that in the Sudan, when it is necessary to preserve meat from a carcase for mess purposes, all that is necessary is to remove it a short distance and cover it with branches. The vultures discover without delay the carcase and pick it clean, but fail to find the rich supply of meat so near them. The fact appears, therefore, to be that vultures use their telescopic eyes not merely to watch what is taking place over a wide range below them, but to note what their neighbours are doing. If one disappears, the rest in turn fly to the region to find out the cause.

Alexander Meek.

Armstrong College, Newcastle-on-Tyne, August 3.

A Coincidence in Values.

It is to be noted that if the simple multiple "seven" of the atomic heat (6·4) be taken a magnitude is obtained double that of the gram-molecular volume for the ideal gas (22·412 litres). On such a basis of reckoning the "ideal atomic heat" would be expressed by deduction from the ideal gas as 6·403.

Dulong and Petit's law would thus be stated: "The product of the atomic weight and the specific heat of an element in the solid state is constant, and for the ideal solid is exactly $\frac{2}{7}$ths of the gram-molecular volume for the ideal gas."

A linkage exists between the liquid and gaseous states through the gas constants. Although the solid state has not in any great measure adapted itself to what Van't Hoff termed mechanical concepts, we can foresee the existence of a simple connecting link between all the three states of matter. The cynic, of course, will observe that much virtue doth abide in the magic number seven!

The Evolution of Consciousness.

Your reviewer, in a kindly notice of my book in Nature of July 29, p. 147, sums up its general attitude in these words: "All that is, Mr. Tilby tells us, has emerged in a definite historical sequence, and we have merely to accept the fact and not ask why." May I point out that I did not say this, and I do not think it? Indeed, it conflicts rather glaringly with the thought I tried to express.

Certainly we have to accept the facts of the universe in their historical sequence; but we have to do something more than accept them—we have first to discover them before we can accept them. And of the major portion of those facts we are still unaware, as the fundamental contradictions of contemporary philosophers abundantly testify.

But to suggest that we are "not to ask why" is to commit treason against the intelligence. That lazy heresy was once popular in the circles of pious orthodoxy, and it has occasionally infected the more epicurean or more pessimistic type of agnostic. But this merely negative attitude will never satisfy. It is very largely because man has asked why that he

has progressed, and it is because he is still (and rightly) dissatisfied with the answers given that he continues to advance.

There may conceivably be a limit to the acquisitions and interpretations of a finite mind; but man is as yet so evidently in his infancy mentally, psychically, and even politically, that we are in no immediate danger of knocking our heads against that possibly predestined barrier to profitable inquiry. Nor do I for one believe that any such barrier exists. There is manifestly an Unknown, but I should hesitate to describe it as the Unknowable.

A. WYATT TILBY.

Howstean, Finton, Essex.

I AM very glad to accept Mr. Tilby's disclaimer. I did indeed associate his evolution of consciousness with a certain theory of "emergence" made famous in an address to the Psychological Section of the British Association last year. I did not mean to suggest that Mr. Tilby's theory was obscurantist or dogmatic.

THE REVIEWER.

Transparency of Liquids and Colour of the Sea.

IN an earlier note in NATURE (Nov. 24, 1921, vol. 108, p. 402) I pointed out that the scattering of light in its passage through a liquid resulting from the local fluctuations of density, the magnitude of which is given by the Einstein-Smoluchowski relation, should enable its transparency to be determined for the parts of the spectrum in which it does not exercise selective absorption. It should be mentioned that in making an experimental test of this point, account has also to be taken of the scattering resulting from the anisotropy of the molecules, and that there is an important difference between this and the scattering due to density-fluctuations. The orientation-scattering is almost completely unpolarised and is therefore distributed symmetrically in all directions. The density-scattering is polarised and is twice as intense longitudinally as in a transverse direction.

The coefficient of extinction resulting from the joint effect of both types of scattering can be calculated theoretically if the compressibility, refractive index, and the ratio of the components of polarisation in the transversely-scattered light are known. Taking the case of benzene as an example, the coefficients of extinction calculated for the 5461 and 4358 lines of the mercury spectrum, which fall in regions in which there is no selective absorption, are respectively 0·00022 and 0·00060. These values agree very closely with the recent experimental determinations of Martin, and form a striking confirmation of the theory. There is little doubt that the observed transparency of many other liquids will similarly be found to be in agreement with theory when accurate data are available.

The case of water is of special interest. Of all ordinary liquids it is the one for which the coefficient of scattering is smallest, and is therefore most affected by traces of selective absorption. There is an absorption band which is clearly marked up to 0·5 μ, and it is possible that traces of it extend into the blue region of the spectrum. For the 4358 line, the coefficient of extinction calculated theoretically is 0·00006 and Martin's observed value is 0·00012. It seems probable that a little farther out in the violet, the transparency may agree more closely with that derived from the theory of scattering.

The newer data now available enables a quantitative test to be made of the theory put forward by me in a recent paper (Proc. Roy. Soc., April 1922) that the blue colour of the deep sea arises from the molecular scattering of sunlight in water, the thickness of the effective layer being determined by the attenuation of the sun's rays as they penetrate into the liquid. The tentative calculations made in that paper have now been revised. The table shows the theoretical albedo of ocean water expressed in terms of the equivalent scattering by dust-free air at normal temperature and pressure.

ALBEDO OF OCEAN WATER.

Wave-length in μ	0·658	0·602	0·590	0·578	0·546	0·499	0·436
Equivalent kilometres of air	0·5	0·7	1·8	2·8	5·2	7·0	15

It is evident from these figures that the blue of the sea would be much more saturated than the blue of the sky, which is the standard of comparison. The height of the homogeneous atmosphere being 8 kilometres, the sea would be about half as bright as the zenith sky on a clear day. This agrees well with the photometric determinations made by Luckiesh during aeroplane flights over deep ocean water in the Atlantic (*Astrophysical Journal*, vol. 49, 1919, p. 129). Luckiesh makes it clear that the greater part of the observed luminosity of water viewed perpendicularly really arises from light diffused upwards from within the water. His determinations thus appear to furnish a quantitative proof of the theory which attributes the colour of the deep sea to molecular scattering of light.

C. V. RAMAN.

210 Bowbazar Street, Calcutta.

Telescopic Observation of Atmospheric Turbulence.

IN his recent contribution to meteorology, "Physics of the Air" (U.S. Weather Bureau, Washington), Prof. Humphreys refers, in chapters 11, 12, and 14, under the general headings of "Wind Layers" (p. 219), "Wind Billows" (p. 221), "Barometric Ripples" (p. 228), and "Special Cloud Forms" (p. 266), to the demonstration by Helmholtz (translated by Cleveland Abbe, "Mechanics of the Earth's Atmosphere," Smithsonian Institution, 1891) that "adjacent layers of air differ abruptly from each other in temperature, humidity, and density, and therefore may and often do glide over each other with . . . a wave-producing effect." Prof. Humphreys proceeds, of course, to associate these demonstrations with the problems of atmospheric turbulence.

May I be allowed to point out, however, that it is *not* the case, as stated by Prof. Humphreys (p. 219), that "these air waves are *seen* only when the conditions of humidity at the interface are . . . just right" for the condensation of visible clouds. I speak from the experience of personal observations covering, intermittently, a period of upwards of twenty years. These "Wind Billows" or "Air Waves" of Helmholtz's demonstrations are always readily visible in the absence of clouds. The various directions of their flowings, and the order of their temporary stratification, are accurately legible by the method I employ of a projected telescopic image of the sun for the purpose of their observation. The "cautious aviator," instead of succumbing to the idea that he needs must fly in the face of "unknown danger," should know that the early stages of turbulence are—if only the sun is unclouded—at all times conspicuously and spontaneously recognisable by this very simple method of observation.

CATHARINE O. STEVENS.

The Plain, Boar's Hill, Oxford, August 9.

Hesperopithecus, the Anthropoid Primate of Western Nebraska.

By Prof. HENRY FAIRFIELD OSBORN, American Museum of Natural History, New York.

EVERY discovery directly or indirectly relating to the pre-history of man attracts world-wide attention and is apt to be received either with too great optimism or with too great incredulity. One of my friends, Prof. G. Elliot Smith, has perhaps shown too great optimism in his most interesting newspaper and magazine articles on Hesperopithecus, while another of my friends, Dr. A. Smith Woodward, has shown too great incredulity in his article in NATURE of June 10. It is in reply to both these extremes that I have especially prepared for NATURE additional information regarding the fauna and habitat of this new Primate, and additional figures to show the comparison between the small, water-worn, type tooth of the genus (Fig. 2, 1-4) and the teeth which most nearly resemble it.

First, a word regarding the time and circumstances of the discovery of this Primate which happen to have a humorous side. Fresh and very violent attacks on the Darwinian theory have been made during the last two or three years all over the United States, especially under the leadership of William Jennings Bryan, a man of ingenious and fertile mind and persuasive powers of oratory, gifted as a politician and as a religious advocate. As an opponent to Darwinism, Mr. Bryan's attack culminated in his very carefully prepared article in the *New York Times* of Sunday, February 26, 1922, in which he ably fortified his position by long quotations from Prof. W. Bateson's Toronto address recently published in NATURE (April 29, p. 553), and by other critics of Darwinism. The following Sunday, March 5, I replied to Mr. Bryan, and realising that quotations from the highest scientific authorities in the world would not have the slightest influence upon him or his followers, I referred him to the writings of St. Augustine, also to the Holy Scriptures, and especially to a passage in the Book of Job (xii. 8), "Speak to the earth and it shall teach thee." In brief, I advised Mr. Bryan to drop all his books, as well as his attempts to grasp the meaning of the diversity of opinion among scientific writers, and to inquire of the earth only what it had to teach him. I added that he would not necessarily lose his religion, but that he would certainly become an evolutionist.

I presume it is widely known that Mr. Bryan is a native and prominent citizen of the State of Nebraska, and it is certainly a humorous coincidence that on March 14, only nine days after my advice was given, I received from the western part of the State of Nebraska the tooth from which has been named the Ape of the Western World (Hesperopithecus). This is the very first evidence, after seventy-five years of continuous search in all parts of our great western territory, of a Primate of any kind above the ranks of the numerous Lemur-like and Tarsius-like lower Primates which have long been known in our Eocene beds.

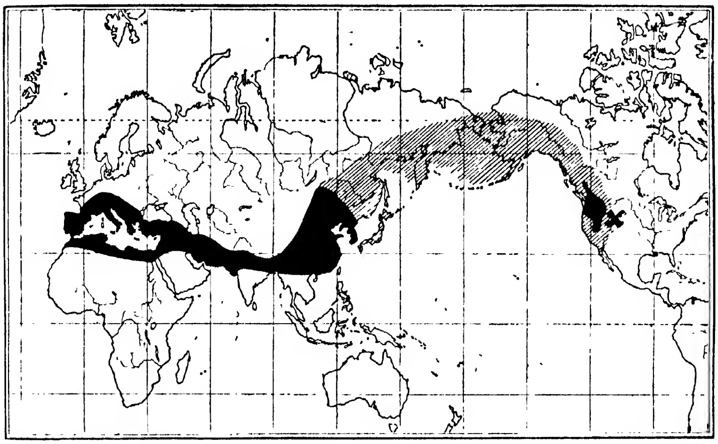

FIG. 1.—Upper Miocene and Pliocene distribution of the Strepsicerine and Hippotragine Antelopes. Known distribution in black, hypothetical migration area in oblique lines. X, Region of western Nebraska, Snake Creek beds, site of the discovery of the Hesperopithecus tooth.

While we have all eagerly looked forward to such a discovery, and I have always regarded it as possible, I have never regarded it as probable, for the reason that the higher Primates, seeking the protection of forests, never venture out for long distances on the plains; moreover, accustomed to a forest fruit supply, they would have been exposed to great dangers in migrating from Asia to western North America except by the aid of a continuous forest belt or of a rather dense forest and savanna belt bordering a plains belt. In 1910 I published in my "Age of Mammals" (page 336, Fig. 156) a map, which I now send to NATURE for reproduction (Fig. 1), with indications of such a life belt for animals of the plains—antelopes and horses; adding an X to show where Hesperopithecus was found.

Since 1910 additional discoveries have been made which tend to indicate the existence also of a continuous forest and savanna belt between eastern Asia and western North America (black area and oblique lines), for we have found animals related to the strepsicerine and hippotragine antelopes, to the plains ungulates remotely related to the kudu, to the sable antelope, and to the eland (Taurotragus). We have also traced the migration of two kinds of forest- and savanna-living mastodons over this entire region, namely: (1) of proboscideans closely related to the *M. arvernensis* of southern Europe, to the *M. sivalensis* of India, and to the *M. mirificus* of western Nebraska, specimens of which have now been found in the very Snake Creek beds in which Hesperopithecus was discovered, also (2) of the true forest-living proboscideans of the genus Mastodon recently recognised in the Snake Creek beds. A true elephant (*E. hayi*), which resembles the *Elephas planifrons* of the Upper Siwaliks of India, has been found in more recent deposits.

From these relatively new and most significant discoveries we may characterise the Snake Creek region of western Nebraska, in Middle Pliocene time, as in the belt of the south Asiatic forest, savanna, and plains fauna, which extends two-thirds of the way around the entire globe, from the region of Britain to the central-west region of the United States, and probably right across to the Atlantic coast. The plains element in this fauna is extremely abundant, especially the Hipparion; somewhat more rare are the true horses (Pliohippus), and still more rare are the remains of the three kinds of antelopes and of the two kinds of mastodons above mentioned. Finally, of the utmost rarity are the remains of the Primates, because during the eight seasons of continuous and expert search we have only discovered two teeth, namely, the tooth now regarded as a third superior molar of an old individual of Hesperopithecus found by Dr. W. D. Matthew in 1908, and the type tooth of *Hesperopithecus haroldcookii* found by the geologist Harold J. Cook in 1921. We are this season renewing the search with great vigour and expect to run every shovelful of loose river sand which composes this deposit through a sieve of mesh fine enough to arrest such small objects as these teeth. Even by this most laborious and painstaking method the probability of finding more material is not very great, for the reason that the anthropoid Primates have always been very clever and resourceful animals, climbing into trees in times of flood, avoiding the low sandy levels and water-courses where ungulates are trapped.

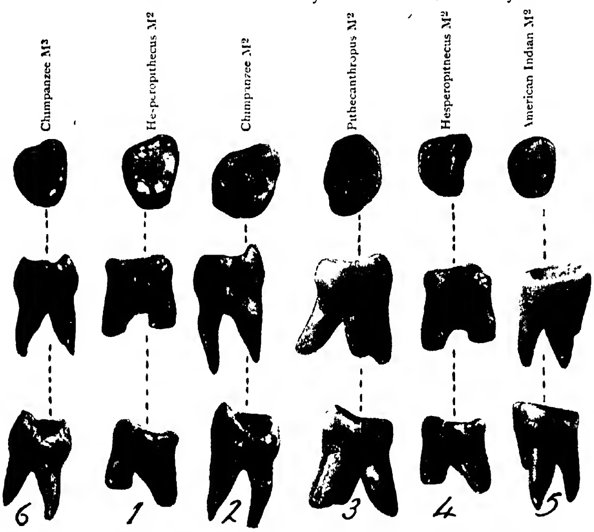

FIG. 2.—Comparison of the Second Superior Molars of the Right Side of the Upper Jaw in the Primates
Upper row crown views of the superior molars
Middle row anterior views of the same teeth
Lower row posterior views of the same teeth
(1) Hesperopithecus, the new Nebraska Primate, middle-aged
(2) Anthropopithecus, a young chimpanzee
(3) Pithecanthropus, adult fossil Ape man
(4) Hesperopithecus (photographed in a different light)
(5) *Homo sapiens mongoloideus*, aged North American Indian
(6) Third superior molar of Anthropopithecus, a young chimpanzee
All photographed to the same scale and natural size

Before re-examining the new figures (Fig. 2) of the Hesperopithecus tooth, may I quote verbally, with some unessential omissions, my own original characterisation of the tooth, for which I alone am responsible.

> This second upper molar tooth is very distant from the gorilla type, from the gibbon type, from the orang type, among existing anthropoid apes it is nearest to m^2 of the chimpanzee, but the resemblance is still very remote. . Thus the proportions of the molar crown of the Hesperopithecus type are about the same as those in the *Homo sapiens mongoloideus* type There is also a distant human resemblance in the molar pattern of Hesperopithecus . to the low, basin-shaped, channelled crown in certain examples of *Homo sapiens* But the Hesperopithecus molar cannot be said to resemble any known type of human molar very closely. The author agrees with Mr. Cook, with Dr Hellman, and with Dr Gregory, that it resembles the human type more closely than it does any known anthropoid ape type; consequently, it would be misleading to speak of this Hesperopithecus at present as an anthropoid ape, it is a new and independent type of Primate and we must seek more material before we can determine its relationships It is certainly not closely related to *Pithecanthropus erectus* in the structure of the crown, for Pithecanthropus has a single, contracted crown in which the superior grinding surface has a limited crenulated basin, whereas Hesperopithecus has a widely open crown with broadly channelled or furrowed margins, and a postero-internal crest suggesting the hypocone of a higher Primate form. . . .

The type description, as published in the American Museum *Novitates*, April 25, 1922, requires little or no modification as a result of two months of intensive research which has been devoted to this tooth, detailed results of which will shortly be published by my colleague, Prof. Gregory. The accompanying new illustrations (Fig. 2), prepared especially

for NATURE, are photographs of a most convincing character, in which the Hesperopithecus molar (Fig. 2, 1-4), in three aspects, is placed directly between corresponding molars of a chimpanzee (right and left) which most nearly resemble it. It will be seen at once (1) that the Hesperopithecus molar, although greatly water-worn, has entirely different proportions from the chimpanzee molar: it is much broader transversely; it is much narrower in the fore-and-aft dimensions. This affords positive evidence that Hesperopithecus had a shorter facial region than the chimpanzee. In this respect it approaches the mongoloid human type (Fig. 2, 5) more closely than it does any of the anthropoid ape types; (2) the roots of the Hesperopithecus molar are much more robust and more human in proportion than those of any of the frugivorous apes; (3) the upper molar of Hesperopithecus, while resembling the upper molars of certain American Indians of mongoloid type in several absolute measurements, differs widely in the more asymmetrical form of the crown, which is broader in front and narrower behind, whereas in the mongoloid human molars the crown is more symmetrical; (4) the type upper molar of Hesperopithecus differs from the corresponding molar in the Trinil Ape-man (Pithecanthropus) (Fig. 2, 3) in nearly all its absolute measurements; but it resembles the Pithecanthropus molar in the great size of the internal (lingual) fang, also in the wide separation of the internal (lingual) and external (anterobuccal) fangs. It also resembles Pithecanthropus in the evenly concave depression of the grinding surface, which is quite unlike the ridged form of the grinding surface observed in a chimpanzee molar (Fig. 2, 2-6); (5) as for the comparison suggested by Dr. Smith Woodward with the third lower molar of the Pliocene bear (Hyænarctos), the differences are so fundamental that it is difficult to find any single point of agreement; the molar of Hesperopithecus very clearly conforms to the flattened tritubercular to quadritubercular type which characterises all the upper molars of anthropoid apes and of man.

Thus, after making due allowance for the characters resulting from the prolonged natural usage of the Hesperopithecus molar, also for characters due to long exposure to erosion and stream action, and to percussion by the sharp sand of the river bed, there nevertheless remain five outstanding characters, as well as many highly significant details of character, which tend to show that this tooth belongs to one of the higher Primates, and that this genus ultimately may be included either within the Simiidæ (anthropoid apes), or near certain ancestors of the Hominidæ (human stock).

I desire to summarise with emphasis my original statements about this tooth, namely, that among existing anthropoid apes it is nearest to m^2 of the chimpanzee, but the resemblance is still very remote . . . that the proportions of the molar crown of Hesperopithecus are about the same as in *Homo sapiens mongoloideus* (American Indian) type . . . that there is also a distant human resemblance in the molar pattern of Hesperopithecus to the low, basin-shaped, channelled crown in certain examples of *Homo sapiens* . . . that the Hesperopithecus molar cannot be said to resemble any known type of human molar very closely. It is certainly not closely related to *Pithecanthropus erectus* in the structure of the molar crown . . . it is therefore ***a new and independent type of Primate, and we must seek more material before we can determine its relationships.***

My original characterisation and description have been fully confirmed by the intensive research of the past two months. I have not stated that Hesperopithecus was either an Ape-man or in the direct line of human ancestry, because I consider it quite possible that we may discover anthropoid apes (Simiidæ) with teeth closely imitating those of man (Hominidæ), just as we have discovered in the true Piltdown man (Eoanthropus) teeth closely imitating those of the chimpanzee. There are so many crisscross adaptations of this kind among the mammals that we can never be sure about the family relationships of an animal until we secure not only the teeth but considerable parts of the skeleton as well. No anatomist in the possession of Pithecanthropus molars only would have discovered the human resemblance which is indubitably established by the roof of the cranium, by the shape of the brain, and by the shape of the thigh bone. For similar skeletal parts of Hesperopithecus we are making most determined and prolonged search in the type locality; it is not at all probable that the desired evidence will be easy to secure. Until we secure more of the dentition, or parts of the skull or of the skeleton, we cannot be certain whether Hesperopithecus is a member of the Simiidæ or of the Hominidæ.

Science in Egypt.

By Col. H. G. LYONS, F.R.S.

THE important part which modern science can play in the economical development of natural resources is generally recognised to-day, but nowhere may this be seen more clearly than in Egypt, with its subtropical climate, its controlled water-supply, and its immunity from the vagaries of the weather which affect more northern latitudes. Here a population which in 1882 was under seven millions has now grown to more than twelve millions, and inhabits a cultivable area which does not exceed seven million acres all intensively cultivated; for much of the area, which was formerly flooded annually and then furnished a single crop after the river had fallen, is now under perennial cultivation with a supply of water at all seasons, and consequently up to five crops in two years are taken from it. Under these conditions the most economical use of the material resources that science can devise, and all the improvements that it can suggest, are of the utmost importance to the country.

During Egypt's period of financial difficulty the provision for scientific work was very meagre, but with the reorganisation of the irrigation and the introduction of reforms, an improving revenue enabled gradually increasing grants to be made to state departments, and many of them have, during the past thirty years, established services in which scientific work of value and importance has been carried on.

Some scientific work had been initiated at a much

earlier date, for the medical school at Qasr el Aini was established early in the last century, and about 1860 a 20-centimetre astronomical refracting telescope by Brunner of Paris, with an equatorial mounting, was set up at Abbassia; a four-metre base-bar together with two 40-centimetre theodolites and a portable transit instrument by the same firm were purchased for the survey of Egypt which was then projected, but which did not become an accomplished fact until about fifty years later.

To-day there are at least a dozen services occupied primarily with work of a scientific character.

The Survey of Egypt is the successor of the earlier surveys of 1823, 1853 and 1878, but none of these were ever completed nor had they any scientifically organised control. It now comprises the cadastral survey, the topographical survey, the desert survey, and the geological survey.

The cadastral survey is of special importance in Egypt on account of the high value of agricultural land, and the exceptional degree of subdivision of the holdings. The network of triangulation on which it is based now covers the Nile Valley and Delta, and is controlled by the first-order triangulation now in progress, which is of the standard demanded in international geodetic work. The topographical survey utilises the material provided by the cadastral survey and adds to it all topographical information besides extending the maps beyond the limits of the cultivated land, to meet the needs of different branches of the public service. There are now published series of map sheets on scales of 1 : 2500, 1 : 10,000, and 1 : 50,000, covering all the inhabited area of the country, while other maps on scales of 1 : 250,000 and 1 : 1,000,000 include the large areas of desert as well.

Survey work as it is extended into the desert assumes a special character, for on account of the large areas to be covered, the difficulties of transport, and the absence of all artificial topographical features, special methods of surveying have been adopted. This work is now in the hands of the Desert Survey, which also undertake the precise location and demarcation of prospecting and mining areas leased by the Government.

On the highly cultivated alluvial plains of the Nile Valley and the Delta accurate levelling is of special importance, so a network of levelling of high precision has been carried over them and extended into the Sudan along the Nile. Besides this the cultivated area throughout Egypt has been contoured at 50 centimetre intervals. At the headquarters of the Survey of Egypt are drawing, photographic, and printing offices in which are produced the maps of the various surveys and also those which are required by the geological survey and by other State departments.

In 1896 a geological reconnaissance of Egyptian territory was authorised which, at the end of five years, developed into a geological survey. The staff has always been small, but a very large amount of valuable work has been done under the difficulties and limitations imposed by desert travel.

Not only have the mineral resources of the country been located and described, thereby becoming available for commercial purposes, such as the phosphate deposits in Egypt and manganese deposits in Sinai, but our knowledge of the structure and stratigraphy of north-eastern Africa has also been greatly advanced, and the interesting fauna of Lower Eocene age which was brought to light in the desert to the west of the Fayum has greatly extended our knowledge of the past history of the African continent. Geological work has been carried out for several years in connexion with petroleum research in the Red Sea area, and the results have been published in various reports. The records of the geological survey and the collections which fill its museum provide a store of information relating to the structure and stratigraphy of the Nile Basin and north-eastern Africa.

The Physical Department, which until a few years ago was part of the Survey Department, and is now a part of the Ministry of Public Works, includes the Helwan Observatory with its time service, the meteorological service, the service of weights and measures, and the hydrological investigations in connexion with the Nile. The observatory, which was formerly at Abbassia, was removed in 1904 to Helwan, 20 km. south of Cairo, because the building at Abbassia was wholly unsuitable and the extension of the electric tramways to its neighbourhood prevented all magnetic work. In it the 30-inch reflecting telescope at Helwan is employed in the photography of southern nebulæ, of comets when they appear, and of Jupiter's eighth satellite, which has been observed almost exclusively by Greenwich and Helwan since its discovery.

The time service is also directed from the observatory, and the observatory clock transmits the noon time signals which are utilised at Cairo, Alexandria, Port Said, and at Khartoum. Magnetic observations are carried out both by means of magnetographs and by weekly absolute determinations. The meteorological service of Egypt and the Sudan includes, besides the central observatory at Helwan, 57 climatological stations, of which 23 are in Egypt, 27 in the Sudan, and 7 in Palestine, and about 230 rainfall stations in Egypt, the Sudan, and Abyssinia. First established to study the conditions determining the Abyssinian rainfall, and consequently the Nile Flood, it has now a much wider importance and is one of the recognised national meteorological services.

The increasing demands of agriculture and its dependence on the supply of water provided by the Nile have necessitated a high precision in river-gauging, and the hydrological work which this involves is now centred in the Physical Department, where the records of 70 river-gauge stations are discussed, and hydrological investigations are undertaken. The storage of water in the valley of the Nile at various points, the need for accurate measurements of the discharge throughout the low stage of the river, the study of the effect of turbulence in the water at flood stage, etc., present a series of physical problems which are of direct importance to Egypt, as well as being of great interest to many other countries.

The department is also charged with the inspection of weights and measures throughout the country, and the prototype standard metre and the secondary standards of length, which were acquired for the purpose of the Survey of Egypt, are now kept at the Helwan Observatory, where any comparisons desired are carried out in a well-equipped comparator house.

Weights are compared with standard copies at the observatory, and sets of certified weights are supplied to all who require them.

The Government analytical laboratory and assay office undertake a large amount of important work which falls under the headings of (*a*) chemical and physical inspection of materials; (*b*) technical chemical consultations; and (*c*) experimental research. Stores and materials of inferior quality frequently find their way on to the Egyptian market, and only by the systematic analysis of material tendered can these be eliminated and economies effected. To the same end the technical clauses in specifications governing supply by contractors are drafted by the staff of the laboratory.

The chemical work carried on in connexion with criminal investigation and other legal matters forms a branch of work which demands much time and great care. Recently published reports indicate that the consultative and research work is at present mainly related to questions affecting petroleum, and the development of petroleum resources in Egypt has given rise to an inquiry into the actual conditions under which petroleum products are used in Egypt, which was undertaken by the laboratory. The small refinery which the Egyptian Government has recently installed at Suez to deal, in the first instance, with royalty petroleum only, but with a view to its ultimate extension if that is found to be desirable, is also under the supervision of the director of the laboratory.

The first medical school in Egypt was formed in 1827 at Abu Zabel by Clot Bey, a French doctor in the service of Mohammed Ali, and ten years later it was transferred to Qasr el Aini on the south side of Cairo, where it still remains. For many years the number of students was small, but of late the school has been much enlarged and the number now amounts to 387. Attached to the school is the Qasr el Aini hospital, and these two form an important centre of scientific work in the country. There are now in the medical school well-staffed departments of biology, physics, chemistry, anatomy, physiology, pathology, and pharmacology, and in all of these not only is instruction given to students but research is carried on by the staff.

Although the number of scientific men in the institution has until recently been too restricted to admit of much research being undertaken in addition to teaching, several important investigations have been carried out; among these may be mentioned the study of the anatomy and racial characteristics of the ancient Egyptians, and of those neighbouring races whose remains occur in the cemeteries of the Nile Valley, and the comparison of them with the present inhabitants has added greatly to our knowledge of the Mediterranean peoples; the investigations which have been carried out of the life history of Ankylostoma and Schistosomum (Bilharzia) have done much to place our knowledge of these on a sound basis, the Bilharzia organism having been discovered in these laboratories, while work of no less importance has been done on the treatment of the diseases which are caused by these parasites. Valuable work on pellagra has also been done recently. Not only is there much more to be investigated in the interest of Egypt itself, but the special conditions, climatic, racial, etc., which occur there provide opportunity for many promising lines of research.

The Department of Public Health, which dates from 1886, is also actively working in the same scientific field and, in addition to the administrative work which it carries on throughout the country, maintains several branches specialising in scientific work. Under the director of the laboratories of the department the water service carries out a regular inspection of all public water supplies, whether in the hands of the Government, municipalities, companies, or private individuals. The examination of substances having a direct bearing on questions of hygiene, such as foodstuffs, drugs, etc., is also undertaken in these laboratories, as well as the chemical and bacteriological examination of water.

Here too research on the main diseases of the country, ankylostoma, bilharzia, and typhus, is in progress with the co-operation of eminent specialists, and in this connexion the recent work of the late Mr Bacot and of Dr. Arkwright will be recalled. An antirabic institute provides for the treatment of persons bitten by rabid animals. The annual reports of the Department indicate the wide scope of the scientific investigations which have to be undertaken in the course of its work, and highly expert assistance must without doubt be employed if they are to be brought to a successful conclusion under the peculiar conditions which an arid subtropical climate provides.

The special conditions which obtain in Egypt, a highly fertile soil, a controlled water supply rendering agriculture independent of rainfall, and a moderately hot climate, form the foundation of its agricultural wealth; the prosperity of the country depends on the efficiency with which these favourable conditions are utilised, and to this end the irrigation engineer, the entomologist, the economic botanist, and the agricultural chemist are working in co-operation. Perennial irrigation has now been extended until about half the cultivable area is supplied with water at all seasons of the year, with the result that in normal years about 32 per cent. of that area is occupied by cotton. It will be evident therefore that the scientific institutions of the Ministry of Agriculture are of the highest national importance, and on their efficiency Egypt's prosperity must mainly depend.

In 1919 a Cotton Research Board was appointed with the object of bringing together the heads of all the technical departments which were interested in the cotton crop, and to ensure that all problems relating to it were dealt with as adequately as possible. It was also to provide laboratory accommodation for investigators engaged in research on cotton. In its first annual report published last year the experimental work upon cotton which had been undertaken was reviewed, and a programme for further work at the scientific institutes of the Ministry was outlined. These institutes include laboratories, experimental farms, gardens, etc.

The chemical laboratory of the Ministry, which undertakes examination and study of soils, water, manures, feeding stuffs, and agricultural products, is situated close to the botanical laboratory and the experimental farm. The work carried on at these has for its object the improvement of cotton, wheat, and

other crops which are grown in the country, on the basis of field selection combined with self-fertilisation and hybridisation. One important and promising research which is in hand is the effect of the gradually diminishing "sharaki" (waterless) period on the soil flora. Propagation in bulk of improved strains of wheat and cotton is arranged with the State experimental farm and with selected private cultivators. The fungoid and bacterial diseases of Egyptian crops in general and of cotton in particular are investigated, and means for their control are devised and tested.

The supply of trustworthy cotton seed of the best growths is so important in order to produce a high quality of staple, and the opportunities of mixing good seed with inferior qualities before it reaches the cultivator are so many, that the Ministry actively interests itself in the matter, through the botanical laboratory.

To this may be added the important work which is being done on the flowering-curve method as an index to the effect of environmental conditions; or investigations of the causes of bud-shedding; and on the root systems of cotton plants. Similar attention is being paid to millet, rice, opium poppy, beans, and sesame; and sugar cane will be added shortly.

The Entomological Section undertakes the study and investigation of insect pests and advises on methods for their control. The fumigation of all cotton seed produced in the ginneries of Egypt is also controlled by this section, and samples of the seed obtained from ginning are sent to it for germination and examination for worms.

The work of the horticultural section should also be mentioned, for in it much work is being done in introducing and acclimatising new species or varieties of trees, and farm and garden plants.

Thus a beginning has been made to provide the scientific organisation necessary for the development of agriculture on sound lines, but something on a larger scale will be needed before it can be adequate to the country's requirements. In these institutions a number of questions of first-rate importance to the Egyptian cultivator are under study, such as the effect on the cotton crop of a high subsoil water-table, of rotation in irrigation, of reduced watering, and many others, and for their satisfactory solution the provision and efficient maintenance of a highly trained and experienced scientific staff is essential.

The scientific diagnosis and investigation of animal diseases are carried out at the veterinary pathological laboratory which was opened in 1904, and the Serum Institute, which dates from 1903, provides the anti-cattle-plague serum required for the immunisation of cattle against cattle plague both in outbreaks and as a preventive measure.

Outside the State departments science is not widely represented in Egypt. There are a few scientific societies, of which the oldest is the Institut d'Égypte, which was founded in 1859; its object is the study of all that concerns Egypt and the surrounding countries from the literary, artistic, and scientific points of view. The Geographical Society was founded in 1875 and publishes bulletins and memoirs at intervals. In 1925 the fiftieth anniversary of its foundation is to be the occasion of an international geographical conference.

The Cairo Scientific Society, founded in 1898, is an active institution which meets fortnightly throughout the winter half of the year and publishes its proceedings monthly in the *Cairo Scientific Journal*. At Alexandria a hydrobiological institute has been recently established, and much important work awaits the scientific research which should be undertaken there. But these are all too few for the needs of the country, and their paucity suggests a lack of appreciation of the importance of scientific knowledge.

In spite of difficulties due to the war, which Egypt has experienced in common with most other countries, science has of recent years been playing a more and more important part in the development of the country and its resources. The conditions there prevailing often differ widely from those which have been studied in other countries, and much research by scientific men of high training and wide experience will be necessary before the many problems which present themselves are solved. Such work is not in the interest of Egypt alone, for much that is done there will, if it is of a high scientific standard, be a permanent addition to the general stock of knowledge. Egypt in the past has benefited largely by the science and technical skill which has been gradually built up by generations of students in many lands, and she may now furnish her own quota in return by scientific research in the many fields of inquiry which the Valley of the Nile affords.

Gelatin.

By Dr. T. Slater Price.

GELATIN, in the form of glue, has been so long known that, according to Dr. Bogue (*J. Franklin Inst.*, 1922, vol. 193, p. 795), "we are unable to penetrate the archives of the human race to a date where we may say with assurance that glue was not yet discovered. Certain it is that this material was in use as an adhesive in the days of the great Pharaohs of Egypt." As glue, or κόλλα, it has given us the term "colloid," and at the time when this term was first used by Graham it was supposed that all colloids were substances of very complex constitution, such as is glue. This, however, is by no means the case, since what are known as the suspensoid colloids may consist of the elements themselves, *e.g.* colloidal gold and silver. The emulsoid colloids, however, consist to a large extent of very complex chemical substances, as, for example, the proteins, and it is to this class that gelatin belongs. Because of its complex constitution the chemical investigation of gelatin and of the processes which occur in its extraction from bones and hides is still in its infancy, and essentially progress has only been made in the direction of the examination of the degradation products. It is therefore not to be wondered at that the enormous literature on gelatin consists, to a very great extent, of accounts of results obtained in the investigation of its colloidal properties.

Naturally, the earliest physical properties to be investigated were the viscosity of the sol and the swelling of the gel, and it was soon found that the relations were very complicated, depending on previous history, even in systems made up from gelatin and pure water alone. For example, shaking, or repeated passage through a viscometer, will decrease the viscosity of a gelatin sol; at ordinary temperatures the viscosity of a freshly made sol gradually increases, whilst that of a freshly diluted sol gradually decreases; in a freshly made gel the intensity of the Tyndall effect gradually increases; and so on, all indicative of the formation of a structure and of the attainment of an equilibrium of some kind.

If the results obtained with gelatin in pure water are so complicated it is no wonder that they are still more so in the presence of acids, bases, and salts. Von Schroeder showed that in the presence of either hydrochloric acid or sodium hydroxide a maximum viscosity of the sol is attained at a low concentration of either of these substances. Again, according to other investigators, the effect of equivalent (tenth normal) solutions of various acids on the swelling is indicated by the following series, which is known as a Hofmeister series, after the investigator who was the first to examine the effects of different salts on the physical properties of the proteins:

$$HCl > HNO_3 > \text{acetic acid} > H_2SO_4 > \text{boric acid}$$

With the sodium salts of various acids the swelling decreases in the order:

Thiocyanates > iodides > bromides > nitrates > chlorates > chlorides > acetates > tartrates > citrates > sulphates

Moreover, the order in the series may be affected by the concentrations of the substances used.

Such series are very difficult to understand, since the order of the compounds does not bear much relation to their ordinary chemical properties; for example, it is difficult to understand why acetic acid comes between nitric and sulphuric acids.

A way out of such difficulties has been found in recent years by the realisation that gelatin, like other proteins, behaves as an amphoteric substance and that its properties in solution depend on the hydrion concentration. For progress in this direction we are chiefly indebted to the work of Procter in England, Pauli in Austria, and Loeb in America, the basic ideas being due to Michaelis and Sorensen.

Gelatin is a stronger acid than base, so that hydrion, in the form of an external acid, has to be added to the solution in order to bring the gelatin to the isoelectric condition. At the isoelectric point the hydrion concentration, C_H, is approximately $2{\cdot}5 \times 10^{-5}$, that is, the pH ($= -\log C_H$) is 4·7, which is on the acid side of the neutral point of water (pH = 7·0). The theory of amphoteric electrolytes shows that at the isoelectric point their solutions should contain a maximum number of neutral particles and should therefore possess peculiar properties; in accordance with this it is found that the properties of swelling, viscosity, osmotic pressure, etc., show a minimum at that point.

On the acid side of the isoelectric point, *i.e.* at pH < 4·7, gelatin should behave as a base and form gelatin-acid salts, whilst on the alkaline side, pH > 4·7, it should act as an acid and form metal gelatinates. Loeb has endeavoured to show that this is true in several ways, of which the following may be quoted, where use is made of silver nitrate and gelatin which is brought to different pH's, all *less* than pH = 7·0, by treatment with varying concentrations of nitric acid. It can be predicted that on the alkaline side of the isoelectric point the gelatin, when treated with silver nitrate, will combine with the silver forming a silver gelatinate, and that the amount formed will be greater the higher the pH. If such a silver gelatinate is formed the silver should not be readily washed out by water and should remain in the gelatin after washing. On the acid side of the isoelectric point the gelatin should form gelatin nitrate, and it should be easy to remove the silver by washing. The following analytical figures show the agreement between theory and experiment.

c.c. 0·01N·Ag in combination with 0·25 gm. Gelatin at different pH's

pH	3·6	3·7	3·9	4·1	4·3	4·6	4·7	5·0	5·3	5·7	6·1	6·4
c.c.	0·5	0·3	0·3	0·2	0·2	0·2	0·55	1·25	3·2	4·0	4·85	4·9

The retention of the silver by gelatin at a pH > 4·7 is well shown by the fact that if test tubes containing samples of the various gelatins are exposed to light, those which are on the alkaline side of the isoelectric point blacken, whereas those on the acid side do not, but remain transparent even when exposed to light for months.

Results similar to those with silver nitrate are obtained when a nickel or copper salt is used. With potassium ferrocyanide the gelatin should retain the ferrocyanide, as gelatin ferrocyanide, on the acid side of the isoelectric point, and this is found to be the case.

Results such as the above indicate the necessity of knowing the pH when any investigations are carried out, and also of making comparisons of any particular property at the same pH. When such comparisons are made, Loeb has shown that the Hofmeister series, with their anomalies, disappear; for example, the various monobasic acids, and acids such as phosphoric, oxalic, and citric acids, which dissociate into two ions at ordinary dilutions, have the same effect on swelling, viscosity, etc., at the same pH. Dibasic acids, such as sulphuric acid, which dissociate into three ions at ordinary dilutions, should, and do, give different effects from the monobasic acids. Similar results were found with alkalis, and abnormal effects produced by such salts as sodium acetate were shown to be due to the alteration of the pH of the gelatin solutions when the salt was added.

The increased swelling, viscosity, etc., which take place on either side of the isoelectric point and reach a maximum at pH's of about 3·5 and 8·5 respectively, are attributed by Pauli to the greater hydration of the gelatin ions formed, as compared with that of the neutral molecule, but Loeb is not in agreement with this. The latter postulates the existence in any protein solution of molecularly dispersed particles, floating side by side with submicroscopic particles occluding water, the amount of which is regulated by the Donnan equilibrium (Procter was the first to apply the Donnan equilibrium to the study of gelatin solutions). The osmotic effects are determined by the molecular particles, the viscosity effects by the submicroscopic particles. Any influence in the solution (change in H-ion concentration) by which the molecular dispersion

is increased at the expense of the solid particles will result in an increase in the osmotic pressure and a decrease in viscosity, and the opposite conditions would result in the reverse of these effects.

The quantitative investigation of the physical properties of gelatin seems to have passed through three phases: in the first phase it was treated mainly as a colloid, in the second mainly as an amphoteric electrolyte, and now, in the third phase, as illustrated by Loeb's latest ideas, it is being realised that both its amphoteric and colloidal properties must be taken into account, since both play a part in its industrial applications. For example, its action as a protective colloid is of great importance in the preparation of photographic emulsions, but in the operations of developing and fixing its behaviour as an amphoteric substance must be considered, as may readily be realised when one remembers that the usual developers are alkaline, and that acid fixing baths are often used; the swelling of the gelatin film will vary in the baths, and in the change from the developer to the fixing bath the gelatin must, at some time, pass through the isoelectric point.

The structure of gels has been a bone of contention for a long time. Nägeli assumed that gels were two-phased and that the solid phase was crystalline, but Scherrer has not found any indication of crystalline structure in gelatin when examined by the X-ray method. Butschli and van Bemmelen have advocated a cell-like structure, forming a net-work, and Hardy concluded that the solid phase consists of a solid solution of water in gelatin and the liquid phase a solution of gelatin in water; Wo. Ostwald has put forward the idea of a two-phase liquid-liquid system. Procter postulates the existence of a solid solution of the exterior liquid in the colloid in which both constituents are within the range of the molecular attractions of the mass, and Loeb has extended this idea. At the present time the conception of a fibrillar structure, as advocated by McBain and his co-workers for soaps, is gaining ground and is especially supported by Bogue in America and Moeller in Germany.

Current Topics and Events.

PROF. E. G. COKER was recently presented in London with the Howard N. Potts gold medal of the Franklin Institute of Philadelphia, awarded to him in recognition of his recent work on photo polarimetry. His method of determining stress in models of pieces and shapes made of homogeneous nitro-cellulose material was brought to the attention of the Institute's committee on science and the arts in February 1921, and it was found that the General Electric Company of Schenectady, New York, had in use Prof. Coker's apparatus. A committee was appointed to investigate the apparatus and method, and it reported that Prof. Coker's work was in the highest degree worthy of recognition by the Institute on account of the ingenuity and experimental skill shown "in applying the principles of photo elastimetry to the study of the magnitude and distribution of strains in models of pieces and shapes under stress." The medal, with the accompanying certificate and report upon which the award was made, was presented to Prof. Coker at a dinner at the Savoy Hotel by Dr. R. B. Owens, secretary of the Franklin Institute.

SOME very remarkable achievements in gliding, or soaring flight, are described by the Berlin correspondent of the *Times* in the issue of August 21. The flights were made by two of the competitors in a test competition on the Wasserkuppe, near Fulda, for the grand prize for motorless sail-planes offered by the German Aeronautical Industrialists Union. On August 18 one of the competitors, Herr Martens, remained in the air forty-three minutes, cruised over the starting-place, and then flew due west, at an altitude of about 320 feet, a distance of ten kilometres, landing comfortably in a meadow near Weyhers. On the following day Herr Hentzen remained in the air about one hour forty-five minutes at an altitude varying between three hundred and six hundred feet, then cruised to the starting-line and across country, landing also in Weyhers, near the spot where Herr Martens had landed the day before. His total time in the air was two hours and ten seconds. The wind was west-north-west, a moderate breeze with occasional gusts. It died away as he set off for the cross-country flight. The machine flown by Herr Martens was a monoplane, designed by the Science Section of the Hanover Technical High School, in conjunction with the Hanover Flying School. The *Times* correspondent gives the following details of its structure: span, 39·4 ft.; wind surface, 172·2 sq. ft.; surface pressure, 2·4 lb. to the sq. ft. The pilot sits directly under the plane. The controls are worked by both the hands and feet. Lilienthal's glider, the correspondent recalls, had a span of 23 ft. and a wind surface of 151 sq. ft.

WE learn from *Science* that from the list of applicants for the Bishop Museum fellowships Yale University has selected the following fellows for the year 1922–1923: Dr. H. W. Fowler, ichthyologist, Philadelphia Academy of Science; Dr. N. E. A. Hinds, instructor in geology, Harvard University; and Dr. Carl Skottsberg, director of the Botanical Garden, Göteborg, Sweden. Dr. Fowler will devote his attention to a study of the fish of Hawaiian waters; Dr. Hinds will continue his investigations of the geology of the island of Kauai, and Dr. Skottsberg proposes to make a study of the flora of Hawaii with particular reference to comparison with the plant life of Juan Fernandez and other islands of the south-east Pacific. The four Bishop Museum fellowships yielding one thousand dollars each were established in 1920 by a co-operative agreement between Yale University and the Bernice P. Bishop Museum of Honolulu. They are designed primarily for aid in research on problems in ethnology and natural history which involve field studies in the Pacific region.

On September 18 to 24 will be held at Leipzig the Centennial Festival of the Gesellschaft Deutscher Naturforscher und Ärzte (Association of German Men of Science and Physicians). The meetings will be preceded by a series of lectures and demonstrations in scientific microscopy to be given at Leipzig University. At the festival an exhibition will be held and a number of papers read by leading German men of science. Among the latter are the following: "The Theory of Relativity in Physics," Dr Einstein; "The Theory of Relativity in Philosophy," Dr Schlick; "Restorative Surgery," Drs Bier and Lexer; "A Century of Atavistic Research," Dr Johannsen (Copenhagen); "External Phenomena and Atavism," Dr Meisenheimer (Leipzig); and "The Theory of Human Atavism"; "Progress and Retrogression in the Course of the World's History"; "Germany's Climate"; "The Highlands of Tibet and their Inhabitants," by Dr Sven Hedin. Following the festival will be a series of continuation courses in medicine to be given at Leipzig, while during the period of the meetings special theatrical performances and concerts are to be arranged. Any one interested in medicine or natural science may take part in the meetings for a fee of 100 marks (or a correspondingly higher fee in the case of foreign countries). Those who wish for further particulars should apply to the Association at Leipzig.

The autumn meeting of the Institute of Metals will be held at Swansea on September 19-22. On the evening of the opening day the first annual lecture on subjects of practical interest to those engaged in the non-ferrous metals industry will be given by Dr R. S. Hutton, on "The Science of Human Effort (Motion Study and Vocational Training)." There will be a number of social functions and visits to works, and the following are among the communications to be submitted: Sixth report to the Corrosion Research Committee on the Nature of Corrosive Action and the Function of Colloids in Corrosion, Dr Guy D. Bengough and J. M. Stuart; report to the Aluminium Corrosion Research Sub-committee on Experiments on the Oxide Method of Determining Aluminium, J. E. Clennell; "Grain-size and Diffusion," Prof. J. H. Andrew and R. Higgins; "The Structure of Eutectics," F. L. Brady; "The Antimony-bismuth System," M. Cook; "The Effect of Superheated Steam on Non-ferrous Metals used in Locomotives," Sir Henry Fowler; "The Constitution and Age-hardening of Alloys of Aluminium with Copper, Magnesium, and Silicon in the Solid State," Marie L. V. Gayler; "Intermetallic Actions: the System Thallium-arsenic," Q. A. Mansuri; "The Effects of Overheating and Melting on Aluminium," Dr W. Rosenhain and J. D. Grogan; and "The Copper-rich Aluminium-copper Alloys," D. Stockdale.

The programme arranged for the Engineering Section of the British Association at the Hull meeting is somewhat of a departure from those of recent years. Two mornings are to be devoted entirely to papers and discussions on single definite subjects, and every effort has been made to arrange the programme in such a way that ample time will be available for discussion. The subject for Thursday, September 7, is "The Strength of Railway Bridges"—a vital topic at the present moment, when bridges are being subjected to loads very much in excess of those for which they were originally designed. Papers on the subject will be read by the engineers of some of the leading railway companies. On Friday, September 8, a descriptive paper will be read on "The Equipment of a Modern Portland Cement Works." The manufacture of cement is one of the leading local industries, and a visit will be paid to the new works of the Humber Portland Cement Co., which have been recently equipped on the most up-to-date lines. A paper of interest to the cement industry will be that on the effect of fire on reinforced concrete buildings. On Friday morning also the president, Prof. Hudson Beare, will give his presidential address on "Some Australian Railway Problems." Monday morning, September 11, will be devoted entirely to a discussion on "Economic Steam Production, with special reference to Marine Practice," and papers on the subject will be read by representatives of the Fuel Research Board, the Admiralty, and Messrs. Babcock and Wilcox. On Tuesday morning a paper on a closely allied and highly controversial subject, viz. "The Propelling Machinery of the Cargo Carrier of the Future," will be read by one of the leading engineers of Messrs. Beardmore and Co., who have done a great amount of work in developing the oil engine for this purpose. On Wednesday morning a paper on the resolution of compound stresses will be read and also one on electrical ignition apparatus for internal combustion engines, and a demonstration of the Collins micro-indicator for high-speed engines will be given. A number of afternoon visits to works and objects of engineering interest has also been arranged.

The meetings of Section M (Agriculture) of the British Association at Hull are to be held under the presidency of The Rt. Hon. Lord Bledisloe, whose presidential address is to be on the subject of "The Proper Position of the Landowner in Relation to the Agricultural Industry." Following the practice introduced by Mr. Orwin last year, Lord Bledisloe will circulate his address and invite a discussion on his views. This will take place on September 11. In the programme of the section are three joint meetings and discussions with other sections. The first of these on the opening day—Thursday, September 7—is to be held at 11.30 A.M., and will be opened by Sir William Beveridge on the subject of "Weather Cycles in Relation to Agriculture and Industrial Fluctuations." This meeting is in association with Sections A and F (Mathematics and Physics, and Economics). Contributions have also been promised by Mr. Udny Yule and Mr. R. A. Fisher. On the following day a meeting will be held at 11.30 A.M. jointly with the Physiology Section to discuss the subject of Vitamins. This discussion will be opened by Prof. Drummond, and Messrs.

Golding, Orr, and Prof T B Wood have promised to take part The other joint discussion is also with the Economics Section, and should prove of wide interest, as the subject is "The Possibility of Increasing the Food Supply of the Nation" Sir John Russell, Sir T H Middleton, Mr C S Orwin, and Prof Somerville have promised to speak from the agricultural side Sir A Daniel Hall is reading a paper on "Land Reclamation on the East Coast," and an excursion to see natural and artificial warp-land should be interesting in this connexion Prof T B Wood is contributing a paper embodying some of the results which have been obtained in the work at the Animal Nutrition Institute at Cambridge Among other interesting papers are several dealing directly or indirectly with the use of lime in the improvement of soil conditions and with the evaporation of water from soil Horticulture and the nutrition of fruit trees will be dealt with by Mr H V. Taylor and Prof B T P Barker, and farm costs in Yorkshire by Dr A G Ruston In addition to the excursions already mentioned another has been arranged to enable members to see something of the farming of the Yorkshire Wolds, and it is also hoped to visit some of the oil-cake factories in Hull

THE Toronto correspondent of the *Times* announces that the Quebec Government has decided to set aside about 22,000*l* for the purpose of establishing a Radium Institute, under the control of the University of Montreal, for the experimental treatment of cancer

ACCORDING to the Spanish journal *Iberica*, two underground railways are now in course of construction in Barcelona, viz the Ramblas-Gracia, of a total length of 3400 metres, and the Puerto branch 1800 metres in length The two lines, which will be double-track systems, are of 1 435 metres gauge The construction of the system will be a matter of some difficulty, as most of it will be underground tunnel-driving, although a certain part, serving traffic in the busiest part of the city, will be in the open Little difficulty is experienced as regards water, because most of the ground through which the tunnels will be driven consists of a thick stratum of quaternary clay, superimposed in places by strata of hard limestone marl The method of construction adopted is the Belgian system The diameter of the tunnels on the straight will be 7 metres, and in curves, etc , 9 05 metres

A CORRESPONDENT informs us that the admirable drawings referred to in a review of Messrs Heron Allen and Earland's report on Antarctic Foraminifera in NATURE of August 19, p 241, were by *Mrs* M H Brooks and not *Mr* M H Brooks as therein stated

THE Cambridge University Press promises for the autumn "The Air and its Ways," by Sir Napier Shaw The volume will contain the Rede Lecture for 1921 and other contributions to meteorology, for schools and colleges

Our Astronomical Column.

COMETS — A photograph of Skjellerup's Comet, 1922*b*, was obtained on July 31 at Greenwich it confirms the short period, which appears to be very close to 5 years, thus making it definitely the second shortest cometary period That of Encke's Comet is $3\frac{1}{3}$ years, that of Tempel's Second Comet is $5\frac{1}{6}$ years The identity with Grigg's Comet, 1902 II, is rendered almost certain, since both the period and the other elements accord closely The perihelion distance has increased considerably, but only by an amount comparable with that which has occurred in the case of the Comet Pons-Winnecke

The *Journal des Observateurs* of August 15 contains a series of observations of Reid's Comet, 1922*a*, made at Santiago da Chili by Rosario Castro There are twenty-two days of observation, from February 6 to March 31 The places of the comparison stars are taken from the Perth Astrographic Catalogue The comet was observed for $2\frac{1}{4}$ months, so that there is ample material for deducing the orbit As the later observations deviate considerably from Mr Wood's ephemeris, there is some reason to suspect appreciable departure from a parabola

M Kamensky has made in *Astr Nachr* 5168 a very elaborate investigation of the perturbations of Wolf's Periodic Comet from 1884 to 1919, due to Venus, Earth, Mars, Jupiter, and Saturn The comet was observed at five apparitions (1884, 1891, 1898, 1911, 1918), and the normal places are all closely satisfied by the final elements, the largest residual being 8″ 6 The perturbations during the above period have been small, the range of the mean daily motion being from 518″·4 in 1898 to 523″ 8 in 1884, or 1 per cent There is, however, a near approach to Jupiter in 1922, which is likely to produce notable changes in the orbit, making it quite doubtful whether it will ever be seen again M Kamensky promises to investigate them It is to be hoped that others will emulate him in similar researches on other periodic comets Those of d'Arrest, Pons-Winnecke, and Tuttle are all in need of such work

THE PROBLEM OF THREE BODIES It has long been recognised that the analytical solution of the general problem of three finite masses, moving under their mutual attraction, cannot be obtained in a form that is of practical utility Something can, however, be learnt of the circumstances of motion, by studying particular cases by the method of mechanical quadratures Researches of this kind are being pursued at Copenhagen Observatory under the direction of Prof E Stromgren Some of the results were published in the Jubilee Number of *Astronomische Nachrichten* and are now reprinted as a brochure There are two cases of special interest where the masses are as 1, 2, 1, the largest being in the centre The first is an approximation to an "orbit of ejection," and involves periodic near approaches The outer masses describe curves resembling *limaçons* (without loops or cusps), while the central one describes a curve resembling the inverse of an ellipse with respect to the centre The other case is an approximation to the case of the arrangement of the three masses at constant distances along a rotating straight line When the conditions for the straight line are slightly departed from each body describes a small loop, that of the central body is practically an ellipse with its major axis perpendicular to the rotating line In each case the motion is periodic, and the curves repeat themselves indefinitely

Research Items.

THE AGE OF STONEHENGE.—In the August issue of *Man* Mr. E. Herbert Stone describes some astronomical enquiries into the midsummer sunrise at Stonehenge. The date, 1840 B.C., given here for midsummer sunrise in line with the axis of Stonehenge must, the writer says, be regarded merely as a rough approximation. Owing to want of precision in the data Sir Norman Lockyer considered that the error—plus or minus—might amount to as much as 200 years; that is to say, the actual date is probably not earlier than 2040 B.C., and not later than 1640 B.C.

THE HULL MUNICIPAL MUSEUM.—Mr. T. Sheppard, Curator of the Hull Municipal Museum, has published a pamphlet giving an account of the collections under his charge. The museum originated in the collections of the museums of the Literary and Philosophical Society, which dates back to 1823. Eventually these collections were made over to the Hull Municipality, and the new museum, which has been improved by numerous gifts and purchases, was opened in 1902. It now contains numerous examples of the Prehistoric, Bronze, and Roman periods, and of the Anglo-Saxon, pre-Viking, and Viking ages, besides more modern productions. The Geological Gallery is an important feature of the institution, which seems to be efficiently conducted. The publication in a cheap form of monographs for the use of visitors is an important part of the work of the museum.

THE FLORA OF THE DAKOTA SERIES.—The Upper Cretaceous flora, so widely known as that of the Dakota Beds, is receiving detailed attention from C. Wilber Berry, who marks out successive stages in the southern states of N. America. His review of these in a paper on "The Flora of the Cheyenne Sandstone of Kansas" (U.S. Geol. Survey, Prof. Paper 129—I, 1922) shows that the term "Dakota flora" has been too vaguely used. The author has proved the Patapsco flora of Virginia and Maryland to be Albian. A comparison of genera gives the Cheyenne Sandstone a distinctly higher position, presumably Cenomanian, since the flora of the Woodbine Sand of Texas (*ibid.*, 129—G) is held to succeed it and to be Turonian rather than Cenomanian. The Woodbine flora is synchronous with that of the true Dakota Sandstone of the western interior, and floras older than this should not now be described as of Dakota age.

DEVONIAN FOSSILS FROM CHITRAL AND THE PAMIRS.—Dr. H. H. Hayden in the course of his journey through Chitral and the Pamirs in 1914 studied the geology and collected the fossils he came across. Of these the Devonian Invertebrata, chiefly Brachiopoda, have now been described and figured by F. R. Cowper Reed (Mem. Geol. Surv. India, New Series, vol. vi., mem. 2). His investigations go to show that in Chitral the Upper Devonian is developed with a fauna of a west European type indicating a Frasnian age; the presence of the Middle Devonian is not proved, but the Lower Devonian is believed to be present. In the Pamirs the Upper Devonian fauna presents a different facies and does not possess a single species in common with the Chitral beds; it is unlike that of any beds of western Europe, but on the other hand, especially as regards the Brachiopoda, is characterised by a certain American element. Beds of Middle Devonian age are also probably present in the Pamirs. As might be expected, a fair number of the species proved to be new and are accordingly named and illustrated on the sixteen accompanying plates, which are of unusual excellence.

THE CRETACEOUS MARINE TRANSGRESSION IN THE AFRICAN REGION.—The investigation by Dr. L. F. Spath (Annals of the Durban Museum, vol. 3, part 2, August 1921) of Cretaceous ammonoidea from Pondoland assigns the strata from which they have been collected to upper stages, Turonian to Campanian. Prof. J. W. Gregory, however, has gathered from the other side of the continent, in Angola, evidence of Albian strata, and it may be concluded that a submergence of some extent took place before the widely recognised Cenomanian transgression. Dr. Spath, following on Mr. R. B. Newton's account of the brachiopods and molluscs, describes the ammonoids from Angola in a memoir in the Transactions of the Royal Society of Edinburgh, vol. 53, part 1, 1922, with handsome plates provided by the funds of the Carnegie Trust. Most of the 117 specimens were collected near Lobito Bay, and not a single Cenomanian ammonite occurs among them. The fauna is compared with that of Albian horizons in Madagascar and India; but the author holds that its closest affinities are with that of the Mediterranean region. Similar relations have been indicated for the Cenomanian fauna of West Africa. The paper includes considerations affecting the classification of ammonoidea from the British Gault.

MOUNT ETNA AND UPPER AIR CURRENTS.—In a paper published by the Reale Accademia Nazionale dei Lincei (vol. xxxi. ser. 5*a*, fasc. 7, 1922), Prof. Filippo Eredia shows that numerous pilot balloon observations conducted at Catania confirm what had been revealed by cirrus clouds and smoke from the volcano, namely, that the upper wind is very persistently from the N.W., and that Mount Etna does not effect any local modification in the general course of the Temperate latitude westerlies, which have been shown by Hildebrandsson to acquire a northerly deviation at the higher levels. The balloon observations in question disclose a definite N.W. direction at all seasons at the height of about 2100 metres (7000 feet *circa*), this direction becoming very persistent at 3300 metres (10,000 feet). It is found that the increase in the speed of the wind with altitude is in the Etna region more pronounced in summer than in winter, and the fact is connected with the greater rotation of the direction of the wind with height in summer, the surface winds in winter being also W. or N.W. The N.W. upper current is styled "il contro-aliseo boreale," that is, the northern counter (anti) trade feeding the tropical high pressure, in accordance with the terminology of Hildebrandsson.

BRAZILIAN CLIMATOLOGY.—An official publication ("Boletim de Normaes, Ministerio da Agricultura, etc., Directoria de Meteorologia"), under the direction of Sampaio Ferraz, has recently appeared, comprising meteorological statistics for a large network of stations scattered over the republic of Brazil, so that, although the records cover but a few years, it is evident that a commencement has been made towards a very thorough climatological survey of this remarkably progressive tropical state. For the capital, however, Rio de Janeiro, situated in lat. 23° S., near the southern tropic, a thirty years' record or more exists for most of the meteorological elements, and it may be of interest to quote a few figures. The annual range of mean temperature is what one would expect in a maritime city at the margin of the tropics, namely, about 10° F. between 77·3 F. in January and 68°·1 F. in July, the figure for the year being 73°·6. The absolute maximum is 102°·2 recorded in December, and the absolute minimum for the period 50·3 in September. Thus frost, which is often quite severe in the extreme south of the republic, has not been recorded in the capital by a wide margin. The mean annual rainfall is 46 inches, with a summer maximum, and the greatest 24-hour fall of 8·9 inches is in no way remark-

able for a hot country, this amount having actually been exceeded in England. The mean annual evaporation exceeds the rainfall by 1 inch—a balance fairly typical of this type of climate. Rain falls on 136 days, and thunderstorms occur on as many as 68 days. The mean annual humidity is 78.3 per cent., with little monthly variation, whilst the vapour tension follows closely the monthly mean temperature. The general subject of the geographical and seasonal variation of absolute humidity is deserving of more study, but it seems almost inevitable that, except perhaps in arid continental interiors away from sources of vapour supply, the dominating factor controlling the variations must be temperature.

CURRENT METERS.—A pamphlet by Dr. M. A. Hogan on "Current Meters for use in River Gauging" has been issued by the Department of Scientific and Industrial Research for the committee on gauging rivers and tidal currents (London: H.M. Stationery Office, 1s. 6d. net). The pamphlet gives in vi + 33 pp. a useful summary of information relating to the conditions affecting the design and use of current meters. Several meters in common use are described, and sections are devoted to a discussion of the effects of oblique and varying velocities, and also of turbulence. Theoretically, the best type of meter is the screw type fixed on a rod, with blades or guard rings specially designed for the good measurement of oblique velocities. But the main disadvantages attached to this type of meter concern the practical details, such as the supporting of the rod during measurement, and in this respect it is concluded that the cup-type meter, being supported by a cable, is more easily manipulated. The results of tests of meters in turbulent water and also for low velocities are collated. The author concludes that in favourable circumstances most meters will give results of sufficient accuracy for river gauging, but that when the conditions are unfavourable, as when turbulence is present, the crude results given by a single meter of any existing type are likely to be considerably in error. The most important effects of turbulence arise through the variations in direction of velocity rather than in magnitude. With the cup type of meter turbulence causes over-registration, while with the screw-type meter it causes under-registration, so that a combination of the two types can be used to measure turbulent flow.

TELESCOPES *versus* FIELD GLASSES.—Although almost every text-book which deals with optical instruments describes the astronomical or Kepler and the Galilean telescopes, and explains how the former may be converted into an erecting telescope like the latter, few of them direct attention to the decrease of luminosity of the field due to the erecting devices, and still fewer give any information as to the relative extents of the fields of view of the two instruments. It is, however, on account of the small field of the Galilean instrument that it is no longer used in astronomical observatories, and some explanation of this restriction of the field should be given in any modern text-book on optics. To fill the gap in present day text-books Dr. A. Sonnefeld, of Jena, contributes an article on the subject to the issue of *Die Naturwissenschaften* for July 28. From the point of view of the instrument-maker wishing to widen the field, the subject has been treated recently by Messrs. Hughes and Everitt, Transactions of the Optical Society, 22, p. 15, and by Mr. T. Smith in the same volume, p. 84.

SPECTRA ON THE QUANTUM-ORBIT THEORY.—This theory has been so successful in describing the known facts as to the spectra of elements constituted of a single nucleus and a single electron, that there is considerable justification in the hope that it may help to explain the spectra of more complicated elements. An approximate solution of the larger problem has been given by Sommerfeld in his "Atombau und Spektrallinien," but there are assumptions made by him as to actual spectral observations which Prof. Hicks points out in a paper on the subject in the August issue of the *Philosophical Magazine* are not justified. In the first instance the expression for the frequencies of the lines of a series which results from taking the atom to consist of a central nucleus, a ring of equally spaced electrons and outside it a single electron obeying the quantum laws, is not general enough to cover all known series. In the second instance observation lends no support to Sommerfeld's deduction that the different types of spectra are obtained by giving one of his constants successive integral values. Lastly, many small and often irrelevant points are referred to as striking confirmations of the theory, which, when examined more carefully, are found to afford no support to it.

HEXOSAMINES AND MUCINS.—Dr. P. A. Levene, in Monograph No. 18 of the Rockefeller Institute, gives the interesting results of his work on constitution of these substances. He shows that the nitrogen in the amino-sugars is present as a primary amino group, in analogy with the other glucosides. A large number of derivatives are described and many of the hexosamines were synthesised. As regards the mucins, it is shown that there are two groups, from one of which chondroitin-sulphuric acid is obtained, from the other mucoitin-sulphuric acid. They differ in the fact that the former, obtained from cartilage, aorta, and sclerotic, contains the amino-hexose, chondrosamine, the latter, obtained from umbilical cord, vitreous humour, and cornea, contains in its place chitosamine. This latter amino-sugar is sometimes called glucosamine. The chitosaminic acid derived from it turns out to be 2-amino-mannonic acid, whereas chondrosaminic acid is 2-amino-talonic acid. Apart from this difference, the two conjugated sulphuric acids are similar and consist of the amino-hexose, glucuronic, acetic, and sulphuric acids in equi-molecular proportions. The amino-sugar and glucuronic acid are combined as a disaccharide. The acetyl group is linked to the amino group. Finally two molecules of the whole are joined as glucoside by their glucuronic acids. There appears to be a slight difference in the place of attachment of the sulphuric acid to the amino-sugar.

THE COMPOSITION OF PHOSPHORITE.—Mr. A. F. Rogers (*Amer. Journ. Sci.*, vol. 203, p. 269, April 1922) writes of "Collophane, a much neglected mineral," and shows that this name deserves a more general recognition. It was given by Fridolin Sandberger in 1870 to an amorphous calcium phosphate and carbonate, with some water, from Sombrero. Sandberger eliminated the carbonate; but the material has been shown by Lacroix to consist almost exactly of $3Ca_3(PO_4)_2.CaCO_3$. Dahllite is clearly its crystallised representative. The author regards the variations in composition as due to solid solution, calcium fluoride and sulphate being sometimes concerned. Collophane becomes important if we recognise that a large part of the ordinary phosphorite of commerce, rock-phosphate and the rest, consists of this material. When the author states that, "like most other amorphous minerals, it is of colloidal origin," he probably means that it once was in a colloidal state. Dahllite has, of course, been previously recognised as forming the concretions of phosphorite in Podolia, which show internal radial crystallisation. Carbon dioxide varying from 2.40 to 11.72 per cent. is recorded by J. Samojlov (*Compte rendu* Congr. internat. géol., 12^{me} session, Canada, 1913, p. 850) as a constituent of the widely spread Jurassic and Cretaceous phosphorites of Russia.

The Glasgow Meeting of the British Medical Association.

THE ninetieth annual meeting of the British Medical Association was held in Glasgow on July 25-28, under the presidency of Sir William Macewen, and its proceedings included much of interest to men of science outside the circles of medical specialism. In his address delivered on the evening of July 25 in the Bute Hall of the University, after welcoming the Association to Glasgow and referring to some of the great names associated with the University of Glasgow during the 471 years of its existence, the president put in a strong plea for a broader scientific outlook with less concentration on purely human phenomena. He referred to the want of scientific training and scientific habits of thought in the general community, and pointed out how this had led to the neglect of discoveries of the greatest practical importance. It had now been discovered that such a disease as syphilis was a preventable germ disease, which could be stamped out by means made known to them. "If this generation did not stop the disease it committed a crime against posterity." The main part of the address dealt with the enthralling subject of brain-surgery, of which the speaker is one of the most distinguished pioneers, and of which he is still an acknowledged master.

On the following three days the Association met in separate sections, housed in the medical and scientific departments of the University, and in various of these papers were read and discussions held which were of wide scientific importance. In the section of pathology an interesting discussion took place on "Animal and Vegetable Pathology in Relation to Human Disease," the openers being Prof. Hobday and Prof. Lang. The former dealt mainly with the importance of diseases communicable to man, such as glanders, rabies, anthrax, and tubercle. Prof. Lang discussed in a more general way the relations of vegetable pathology to animal, tending on the whole to sound a note of caution against the assumption that the principles underlying the processes of disease and healing are identical in the two kingdoms. He discussed the case of crown gall, on which important recent work had been done by Smith and Townsend, and by Robinson and Walkden. In this case tumours developed in relation to wounds such as those made in grafting, and it had been shown that the new growth was due to infection by a specific microbe *Bacterium tumefaciens*. The fundamental differences in organisation between the higher animal and the higher plant should, in Prof. Lang's opinion, be carefully borne in mind before instituting close comparisons between such tumours caused by *B. tumefaciens* and the malignant new growths of man. The probability was that the pathogenic processes of plants and animals had begun to diverge from one another at a very remote period of evolutionary time, and the value of the study of plant pathology to the human pathologist (and incidentally to the student of medicine) lay rather in its broadening the outlook than in its providing the bases for direct inferences from one subject to the other. In the course of his paper Prof. Lang referred to the fact that the study of ancient plants obtained from the Old Red Sandstone of Scotland had disclosed injuries, due apparently to irritating gases, and healing processes, bearing the closest similarity to what may be observed in modern plants after exposing them to irritating vapour. This fact is obviously of extraordinary biological interest as being the most ancient case of pathological reaction which has been subjected to histological investigation.

The discussion just mentioned had its supplement on the following day in the new but highly successful section of micro-biology, sitting under the presidency of Dr. R. M. Buchanan, when Prof. V. H. Blackman opened a discussion on "Some Similarities and Dissimilarities in the Micro-biology of Plant and Animal Diseases." Prof. Blackman also was inclined to emphasise the differences rather than the resemblances between the diseases of plants and animals. He gave an interesting general review of the relations of parasite and host in the parasitic diseases of plants. The immunity of plants towards hostile micro-organisms was a natural immunity; the acquired immunity so characteristic of many human diseases and forming the basis of modern serum-therapy was quite unknown in relation to specific diseases in plants. Immunity was often of a passive kind, such as is provided by a resistent cuticle or cell-wall, successful invaders in such cases making their way in through natural openings such as the stomata, or through special perforations made by their own activity. In other cases the immunity was of an active kind, involving a distinct physiological reaction on the part of the plant. Thus in cereals immune to "rust" the cells have developed a hyper-sensitiveness to the proximity of the fungus, dying upon its approach, before they can be penetrated by the parasite. In other cases the host imprisons the invading parasite in an envelope of impermeable cork cells. Prof. Blackman also directed attention to the existence amongst plants of diseases due to so-called ultra-microscopic organisms. Two diseases of this type occurring in the potato had recently been found to show a further analogy with diseases of a similar type occurring in animals in that they were insect-borne, being transmitted by aphides or green-fly.

The "ultra-microscopic" or "filter passing" organisms were also to the fore at other meetings of the section of micro-biology. On Wednesday, July 26, Dr. F. d'Herelle, of the Pasteur Institute, opened a discussion on his theory of "Bacteriophage," a theory formulated to explain the fact that among the contents of the alimentary canal there always exists a "something" which possesses the power of dissolving bacteria of certain definite types, *e.g.* in the case of man bacteria of the coli-typhoid-dysentery group. This "something," sometimes called an enzyme, sometimes given the more definite name bacteriolysin, is of uncertain origin. The balance of probability would probably appear to most biologists to be in favour of its being formed by the activity of the host, its formation being part of the general defensive mechanism of the body. Dr. d'Herelle, however, believes it to be formed by an ultra-microscopic enemy of the bacteria, which he names *Bacteriophagum intestinale*, and he supports his theory by a mass of striking arguments. Dr. Twort, of the Brown Institute, gave an account of his earlier work, in which he determined the existence of a similar bacteriolytic substance in cultures of *micrococci*. A point of much interest emphasised by Dr. Twort, but usually ignored by biologists, is the probability that ultra-microscopic organisms exist in abundance free in nature, and are not confined to a parasitic existence.

In the discussion on Thursday, July 27, upon the "Bacteriology of Influenza," an important rôle was again assigned to the ultra-microscopic type of organism. Dr. Mervyn Gordon recalled that a large number of diseases, such as measles, mumps, small-pox, were now attributed to these organisms, measuring under 0.5μ in diameter, to which Prowazek had given the name Chlamydozoa. Strong evidence had recently been adduced that the real causative agent

of common cold was an organism of this type, measuring 0·2–0·3 μ in diameter. Dr. Gordon gave an account of his recent researches, which are entirely confirmatory of the view that influenza is similarly due to organisms of this type, which can be obtained from the nasal and pharyngeal secretion during the first three days of the disease, though not later.

The section of physiology met on two days only, each being taken up mainly with an interesting discussion. The first, on the "Etiology of Rickets," opened by Dr. Leonard Findlay and Prof. Mellanby, was mainly of medical interest, but it left two distinct impressions on the lay mind: (1) That there is still much difference of opinion in regard to the cause of this blot on the health of our great cities, and perhaps too great a tendency to the belief that one single factor is responsible rather than a complex of factors; and (2) A strong impression of the valuable return which is bound to accrue to the community through the activities of the Medical Research Council under the guidance of its present secretary.

The other discussion in this section had for its subject "Basal Metabolism," i.e. the metabolism during complete rest. In his interesting opening address Prof. Cathcart incidentally emphasised the extreme complexity and elusiveness of the phenomena grouped under that blessed word metabolism—facts which are liable to be accorded insufficient weight by biological writers and teachers.

One of the most important features of the Glasgow meeting was the discussion which took place on Friday morning, July 28, in the section of medical sociology upon "Alcohol as a Beverage in its relation to certain Social Problems"—a discussion which stood out in strong relief from most discussions on this much discussed subject from its including moderate and calmly reasoned statements from scientific investigations of recognised status. The discussion was opened with an admirable introductory statement by Prof. Mellanby, of Sheffield, in which he laid down the basic facts regarding the physiological action of alcohol. As a drug it was to be regarded as a narcotic, acting on the cells of the cerebral cortex and slackening its control and discipline over the lower nerve centres. It was as a narcotic drug that alcohol in small doses found its usefulness in human life, dispersing temporarily worries and troubles, and so facilitating bodily functions that were known to be interfered with by anxiety. As a food the value of alcohol in moderate amounts rested on the fact that it is rapidly absorbed and to the extent of about 98 per cent. oxidised so as to set free heat. Experiment showed that as much as 40 per cent. of the heat lost from the body during a given period could be supplied by alcohol, but the practical utility of this was to a great extent neutralised by the poisonous drug action. Under abnormal conditions, however, such as those of Diabetes mellitus, the food value of alcohol in small doses could be utilised to take the place of sugar. Dr. J. T. MacCurdy, of Cornell, speaking as a psychiatrist, emphasised the fact that "the Alcoholic is, before he ever touches a drop, an abnormal person," and also emphasised the great difficulty in carrying out a just comparison between the two evils of such abnormality finding expression in alcoholism or in some other form of vice or crime. From the purely scientific point of view one of the most interesting contributions to the debate was that from Prof. C. R. Stockard, of Cornell Medical College, which told of his experiments, extending over a long series of years, on the influence of alcohol in causing abnormalities of developing eggs and embryos. His experiments on mammals (Guinea-pig) were of particular interest in demonstrating how heavily dosing the parents with alcohol produces marked effects in diminishing fertility, in increasing pre-natal and early post-natal mortality, and in causing defectiveness of the offspring. If we are justified, as no doubt we are, in extending Stockard's results to man, we are afforded incidentally a fine illustration of natural selection at work in the civilised community—for these individuals that are afflicted with the particular form of "unfitness" that finds its superficial expression in drunkenness are seen to be subjected to a severe process of weeding-out during fœtal and infantile life which works in the direction of keeping up the standard of the surviving stock.

It must not be thought that the proceedings of the sections exhausted the activities of the meeting. An admirable "Museum" was got together by Prof. Teacher, while Dr. Dunkerly arranged a microbiological exhibition, which included beautiful series of Leishmania and of Spirochaetes exhibited by Sir Wm. Leishman, and Dr. Connal's series of developmental stages of Loa loa in the body of the transmitting fly. Numerous interesting demonstrations were given at the afternoon meetings of the various sections, and the meetings concluded on Friday evening, July 28, with the "popular" lecture entitled "The Physician—Naturalist, Teacher, Benefactor," delivered to a large audience by Prof. Graham Kerr.

The gold medal of the Association was presented to the Right Hon. Sir T. Clifford Allbutt and to Lieut.-Col. A. Martin-Leake at the general meeting on the evening of July 25. The presentations were made by the president on behalf of the association. The medal for distinguished merit was instituted by the association at its annual meeting in Manchester in 1877. The medal is awarded on the recommendation of the Council to some person who shall have conspicuously raised the character of the medical profession by scientific work, by extraordinary professional services, or by special services rendered to the association. On this occasion the medal was in each case accompanied by a testimonial or address stating the grounds of the award.

The Stewart Prize of the Association was presented to Dr. J. C. McVail at the same meeting on July 25. The prize was founded by the late Dr. Alexander Patrick Stewart, who was among the earliest to give attention to sanitary questions and also to distinguish between typhus and typhoid fever. The primary object of the Stewart Prize is to afford recognition of important work already done or of researches instituted and promising good results regarding the origin, spread, and prevention of epidemic diseases.

Broadcasting in America.

MR. A. P. M. FLEMING, manager of the research and education departments of the Metropolitan-Vickers Electrical Co., Ltd., who has been closely identified with the development of radio broadcasting in Great Britain, recently attended a conference of the American Institute of Electrical Engineers at Niagara Falls as a representative of the British Institution of Electrical Engineers and the British National Committee of the International Electrotechnical Commission. He took advantage of the opportunity while in America to make a close investigation of the position of radio telephony extending over a period of two months, and, in addition, studied the trend of public taste and opinion

with regard to broadcasting and the steps which are being taken by the Government to control radio transmission. He tested a wide variety of makes of receiving apparatus and discussed the methods of working, cost and organisation of broadcasting stations, and obtained a considerable amount of valuable experience which will assist in enabling British manufacturers to avoid the pitfalls into which many American firms have fallen. Mr Fleming also visited the largest broadcasting stations and discussed the situation with the leading makers, radio engineers and officials.

Since the end of 1920 the broadcasting position in America has been chaotic. Practically anybody—private companies, municipalities, departmental stores, universities, Government offices, newspapers—have been able to set up transmitting stations, the only restrictions being the wave-length, 360 metres, and the power, about $1\frac{1}{2}$ kw. At the present time there are nearly five hundred broadcasting stations in the United States working without reference to each other, except in a few cases of friendly co-operation, with regard to time of operation, type of programme and object of the station. The stations are concentrated chiefly along the eastern states and on the Pacific slope, and no less than twenty stations are in close proximity to New York City. Broadcasting programmes are announced in advance through the press, and much use is made of gramophone records for transmission. The U.S. Government called a conference of interested parties at Washington a few months ago under the chairmanship of Mr Herbert Hoover, and appropriate working conditions were decided. The passage of a Bill now before Congress will afford the Secretary of the Department of Commerce considerable powers to control and co-ordinate the radio traffic, including broadcasting. The process, however, at this stage is slow, and some time must elapse before the American system is giving the public as efficient service as it is hoped the British system will give from its inception.

The action of the Postmaster-General in restricting broadcasting is viewed with much approval in the States, as affording the most convenient means whereby confusion may be avoided.

During his visit Mr Fleming saw the principal broadcasting stations in operation, including East Pittsburgh (call sign KDKA), Newark (WJZ), Chicago (KYW), Springfield (WPZ), all operated by the Westinghouse Co., the Detroit Free Press, Detroit News, Federal Telegraph and Telephone Co., Rochester School of Music, etc. From the two Detroit stations, as well as those at Pittsburgh and Chicago, Mr Fleming broadcasted for the benefit of American listeners the position of radio telephony in Great Britain.

The broadcasting station comprises studios in which the artistes play and sing, transmission rooms, control rooms, green room and offices. Every station differs from others, all being in an experimental stage of development, and each one has points of interest which can be incorporated into English practice. It is estimated that two million radio receiving sets are in use, and during the last two years about 12,500 companies have been incorporated for carrying on radio business. Many of these, however, are mushroom affairs, against which the public has been warned.

The pioneer work in the development of broadcasting was conducted by the Westinghouse Co., of Pittsburgh, which opened station KDKA in December 1920. The Company also immediately placed upon the market a number of receiving sets and a remarkable demand arose. The whole country responded to this new form of entertainment, and the demand created has no parallel in recent years.

The patent situation with regard to radio apparatus, circuits and valves was so obscure and complicated that many of the leading makers might unwittingly have infringed each other's patents, and the pooling of the patents by the principal manufacturers has eased what might have been an extremely difficult situation. The Radio Corporation, a group of radio manufacturers already in existence and interested in communication by radio telephony, was utilised to act as a selling agent. There are, of course, many manufacturers outside this group, but small makers are not permitted to utilise patents for which they are not licensed, their sets consequently being less effective and up-to-date than those of the leading makers. Clearly the "mushroom" companies are unable to indemnify their clients against actions which may take place if basic patents are infringed by the apparatus they make.

One of the most interesting organisations in the States is the American Relay League, a national non-commercial association of radio amateurs who combine to relay friendly messages between amateur stations across the Continent and to protect the interests of amateurs. In this way messages from amateur transmitting stations can be sent over very much longer distances. Under British conditions such work is not possible, as those who hold 10-watt transmitting licenses can only send out messages connected with the experimental work for which their license is primarily intended, but attempts are being made to modify these restrictions. Amateur transmission could not, of course, take place while broadcasting is in progress.

During the hot summer months in America the public is not particularly keen on indoor entertainment, and noises in the receiving set due to atmospheric electrical disturbances are troublesome. The public taste is also changing, and those who have experienced reception last winter are developing a taste for more serious and solid matter than has hitherto been the case. Educational matter and health talks are becoming increasingly popular in programmes. More and more church services are broadcasted, and the improvement in the quality of sermons is helping to fill churches which have hitherto been very thinly attended. Market and stock reports are also sent out, and these are of great importance to farmers, *e.g.* the ruling price of pork in Chicago, obtained by radio, may help a farmer to decide whether to send his hogs to market or not immediately. University extensions and extra-mural lectures are being broadcasted to an increasing extent, and invalids and others ("shut-ins") who are unable to seek entertainment out of doors find radio a great boon.

There is no doubt that radio has come to stay. Its character will change, both through technical improvements and through changes in the public taste, but it is rapidly becoming a permanent part of the national life. It is being used to an increasing extent to send out what is known as "perishable news," to relieve the load on the ordinary telephone and telegraph lines. In this respect the attitude of the press has undergone a notable change. From opposition it has changed to whole-hearted support. Newspapers publish programmes at length, and have radio columns in which expert advice is given to amateurs.

Mr Fleming is most optimistic as to the future of radio in Great Britain. While British audiences are likely to be more critical than American, with the aid of all that American experience has to offer British broadcasting will establish itself as the best in the world, and the public will find in it a unique and continuous source of entertainment and instruction, full of possibilities of expansion. The develop-

ments which are taking place even now in America are likely to produce far-reaching changes, such as the so-called wired wireless, by which radio transmission is conducted for part of its path by an ordinary wired line. What these developments do, however, must be left for the future to determine.

Third International Congress of the History of Medicine.

THE papers read at this Congress, which was held in London on July 17-22 under the presidency of Dr. Charles Singer, may be classified in four main groups according to their subjects, viz., epidemiology, anatomy, pharmacy, and veterinary medicine. Among the papers on epidemiology special mention may be made of those by Prof. Jeanselme, on bubonic plague in the Middle Ages, in which a relationship between famine and plague was shown; by Dr. Ernest Wickersheimer on the black plague at Strasbourg in 1349, with extracts from a contemporary document; by Miss M. Buer on the decrease of epidemic diseases in the 18th and early 19th centuries, a decrease attributed by her to improvements in agriculture, improvements in house and town planning and the advance in medicine; and an interesting account by Sir William Collins of Sir Edwin Chadwick, the father of English sanitary science. Other papers of epidemiological interest were those of Dr. Torkomian of Constantinople on inoculation against small-pox by the ancient Armenians, of Dr. Belohlavek of Prague on epidemics in Bohemia in the Middle Ages, and of Dr. Neveu of Paris on plague in Tuscany in the fifteenth century.

Perhaps the most interesting contribution to the history of anatomy was the paper of Prof. Wright on Leonardo da Vinci's work on the structure of the heart, in which it was stated that Leonardo was the first to show the exact attachment of the chordae tendineae to the cusps of the auriculo-ventricular valves, the first to direct attention to the dilatations of the origins of the aorta and pulmonary valves, the first to note the occasional presence of an inter-auricular foramen or foramen ovale, and the first to describe the moderator band in the right ventricle of the heart. Dr. Donald Campbell made a communication on the significance of the Arabic MSS. of Galen's work on anatomical administration, in which he suggested that the preservation of this work when portions of it were totally lost otherwise indicated that the Moslems did not completely destroy the second library of Alexandria, as is generally supposed. In a paper on the anatomical studies of Descartes in Holland, M. Fosseyeux showed by extracts from contemporary literature that Descartes, who was the grandson and great grandson of medical men, studied anatomy both in the human subject and in animals at Amsterdam, Utrecht, Leyden, and Harlem between the years 1630 and 1638. Other anatomical papers were those by Dr. T. Wilson Parry on the collective evidence of trephination of the human skull in Great Britain during prehistoric times, by Dr. Kathleen Lander on women as anatomists, by Dr. Krumbhaar of Philadelphia on the beginnings of anatomical instruction in the United States, and by Dr. J. D. Comrie on early anatomical instruction in Edinburgh.

In an historical sketch of pharmacy in Great Britain and Ireland, Mr. J. B. Gilmour showed that it was not until the 16th century that any beginning was made with the regulation of the practice of medicine or the sale of drugs, and even down to the 18th century the sale and dispensing of drugs was chiefly in the hands of the physicians and apothecaries. The paper deals successively with the evolution of the pharmacist, the history of pharmacy law, the origin of the Pharmaceutical Society of Great Britain, pharmaceutical education and science, the protection of professional interests, pharmacy in Ireland, and the history of pharmacopœias and pharmaceutical literature. In his paper on art in the Italian pharmacy of the 15th century Prof. Castiglioni of Trieste stated that at the beginning of the 15th century the practice of medicine was closely associated with that of the apothecary, so that the druggist's shop was often an intellectual centre which served not only as a consulting-room for the doctor but also as a place where books and curiosities were exhibited. Prof. Castiglioni showed a large number of photographs of pharmacy jars from his private collection, illustrating the development of medicine in the 15th century. Mr. C. J. S. Thompson traced the history of "Hiera Picra," a remedy composed mainly of aloes and colocynth, which was first used, according to tradition, in the temples of Æsculapius in Greece and is still sold in the pharmacies of Great Britain and the Continent. M. Buchet contributed a paper on the history of legislation concerning poisons, and M. Fialon described the ancient statutes of the apothecaries of Lyons.

Major-General Sir Frederick Smith gave an interesting description, illustrated by lantern slides, of the position of veterinary anatomy in England during the 16th, 17th, and 18th centuries, in which he emphasised the following points: (1) The comparative absence of information on the subject, in spite of the fact that up to the 15th century practically only the anatomy of animals was studied by students of human medicine. (2) The interest shown by lay writers on a subject in which they were ignorant, but the importance of which in the advancement of veterinary knowledge they fully recognised. These men wrote on the subject and drew on their imagination. (3) The absence of any veterinary school in this country until the end of the 18th century, when one was founded in 1791 with Vial de Sainbel as professor. Prof. F. J. Cole of Reading read a paper on Ruini on the anatomy of the horse, a work which, published in 1598, was the first monograph on the anatomy of an animal. Other papers on veterinary medicine were read by Mr. F. E. Bullock on "Mulomedicina Chironis," a compilation of ancient veterinary treatises, by M. H. J. Sevilla on the syndrome of colic in the Greek Hippiatric writings, and by M. Moulé on the history of glanders in Greek and Roman writers.

In addition to the papers on the history of epidemiology, anatomy, pharmacy, and veterinary medicine, communications on various topics of medico-historical interest were read. In a paper entitled "Magistri Salernitani nondum cogniti," Dr. Capparoni of Rome gave an account of a manuscript which he had found in the cathedral of St. Matthew at Salerno, containing the names of thirty-one hitherto unknown medical men from the second half of the tenth to the sixteenth century, most of whom were monks or ecclesiastics of some kind. This discovery confirmed Dr. Capparoni's view that scientific medicine at this period was mainly practised by monks until the papal prohibition in the 12th century to practise medicine outside the cloisters, with the result that the school of Salerno was founded by laymen. In a paper on Dante and Averrhoism in Italy, Prof. Castiglioni discussed the relations of

Dante with medicine. Though opposed to the view that Dante himself was a medical man, the professor stated that the poet studied medicine at Bologna, was closely connected with Alderotti and Pietro d'Albano, two of the most distinguished physicians of that time, was prior of the corporation of physicians and apothecaries, and was given the title of magister in a contemporary document.

Other papers on miscellaneous topics were those by Dr. F. J. Poynton on doctors and the dawn of aerostatia, by Dr. J. D. van Gils of the Hague on the doctors of Molière and Shaw, and by Mme. Panayotatou of Alexandria on hygiene and dancing in ancient Greece. It is proposed to hold the next Congress of the history of medicine at Geneva in 1925.

The Research Association of British Rubber and Tyre Manufacturers.

PROBABLY in no industry is the old ground of knowledge less thoroughly explored and the new unbroken field for useful research so extensive and attractive as in the rubber industry taken as a whole. A hundred years or a little more have passed since the discovery that rubber could be converted into a workable form by solution in suitable solvents or by mechanical kneading, and the process of vulcanisation was discovered eighty years ago. These operations, which are yet applied unaltered in principle and very little different in practical detail, still represent the foundation of rubber manufacture of the present day; compared with them, all the other innovations have been of minor importance. The disadvantages, however, inherent to these fundamental operations are so marked as to cause surprise that so little further advance has been made during the last half-century. It is almost astounding that so large a portion of the effective history of the industry should be found recorded in the remarkable "Personal Narrative" of Thomas Hancock, published in 1857, after his retirement.

If anything further had been needed to emphasise the importance of the rubber industry, particularly that section of it dealing with the production of rubber tyres for various types of vehicles, and the call for its further scientific development, the period between 1914 and 1918 supplied the necessary stress in an unmistakable manner. It was natural, therefore, that members of certain companies interested in the manufacture of rubber goods should decide to take advantage of the assistance offered by Government to found a Research Association of British Rubber and Tyre Manufacturers. An energetic Committee under the chairmanship of Mr. Alexander Johnson saw the Association pass from the embryo stage to a state of healthy and vigorous existence with Mr. B. D. Porritt as director of Research.

On account of the early part of the year 1920 being inopportune for the purchase of premises and equipment, the Research Association first found a temporary home in University College, London, thus enabling a commencement with a preliminary, albeit necessarily restricted, programme of work, more particularly of a purely physical and chemical nature. Later, after careful search and inspection of suitable premises, purchase was completed of two detached houses at 105 and 107 Lansdowne Road, Croydon. These possessed several advantages, and after necessary alterations have been converted into a prepossessing unit. The space between the two houses is now occupied by a substantial connecting building which provides increased accommodation in addition to inter-communication. The frontage of the site is 120 feet and the depth 206 feet, the latter leaving ample room for future extensions.

The building, which was formally opened by Lord Colwyn on July 26, comprises administrative offices, library, experimental laboratory for the preparation of rubber, incorporation of compounding ingredients and vulcanisation, workshop, mechanical testing laboratory, physical laboratory, chemical laboratories, storage accommodation and caretakers' quarters. All the necessary heavy experimental plant is contained in the basement of the inter-communicating building, and one of the two original houses has been kept entirely free from running machinery in order to permit the use of delicate instruments without risk of disturbance from vibration.

Those responsible for the founding of this Association have realised that the importance of research to industry lies not so much in the possibility of very occasional discoveries of a revolutionary nature as in the sure benefits which are the abundant fruit yielded by the application of science to the improvement of existing methods. The functions of the Association, while not excluding the study of fundamental problems, include more prosaic considerations such as improvement in the control of manufacturing operations and the testing of raw materials and final products. In such directions there is indeed urgent need for work, such vital matters as the reasons for the use and selection of various necessary "compounding ingredients" and the methods adopted for the production of vulcanised rubber possessing special physical properties, *e.g.* resistance to cutting or abrasion, resilience, toughness or even hardness, being based on almost entirely empirical grounds, often of the least desirable type.

Whatever requirement may have to be left unsatisfied in such an Association as this, it should be able to anticipate with the utmost confidence an abundant and unceasing supply of problems for investigation. D. F. T.

University and Educational Intelligence.

PROSPECTUSES of Universities and Colleges for 1922–23 are beginning to appear. Leeds University publishes an extensive programme of evening courses (advanced) in engineering, dyeing, textile and leather industries, and geology, and afternoon courses in coal-mining. During each of five evenings of the week from five to nine classes will be held. The faculty of engineering of the University of Bristol announces additional vacation courses to be held in 1923. University College, Exeter, is establishing new courses, intermediate and final, in horticulture and in agriculture, the final course in agriculture being at the Seale-Hayne Agricultural College, Newton Abbot.

SECONDARY education in the United States is, as every one knows, conducted chiefly in public (that is to say, in State) schools. But the part of the field occupied by the private high schools and academies is not inconsiderable. Advance sheets from the biennial survey of education in the United States, 1918–20 (Bulletin, 1922, No. 9 of the Bureau of Education), show that in 1919–20 there were 2093 of these institutions, attended by 184,153 secondary students and, in addition, 250,000 elementary pupils. A remarkable growth occurred between 1905 and 1920. During this period the number of their secondary students increased by 72 per cent. Nearly 75 per cent. of the institutions are under denominational control; of these 60 per cent. are Roman Catholic, and the following analysis shows that to the Roman Catholic schools is chiefly attributable the above-

mentioned increase in the number of secondary students in private schools. The increase was—in Roman Catholic schools from 20,150 to 76,054; in other denominational schools from 39,106 to 53,965, in non-sectarian schools from 47,951 to 54,134; in all from 107,207 to 184,153 The increase in the number of secondary students of negro race in private schools is also noteworthy—from 2771 in 1905 to 9526 in 1920 Less than half of the total number of these schools are co-educational, 385 being for boys only and 728 for girls only

"We should have a dynamic education to fit a dynamic world" is the burden of the address delivered by Dr. James Harvey Robinson, on "The Humanising of Knowledge," before the American Association for the Advancement of Science, at a meeting with the Pacific division in Salt Lake City on June 23-24. Once it was well to dehumanise science; now it must be rehumanised Dr Harvey thinks there is a real danger threatening the progress of science itself in neglecting the protest of philosophy, that the ideal of dehumanising scientific investigation loses sight of the fact that the onlooker is one of the essential elements in the observing and recording The danger is not that the scientific ideal is faulty, but that mankind will not accept an idea unless it is attractive as well as true "The politicians in the Kentucky legislature think themselves competent to decide whether the State should grant funds to any institution in which man's animal extraction is taught; the politicians in the New York legislature have provided that no one shall teach in the schools of the State who is known at any time to have expressed any distrust of our institutions" We on this side may smile at these fears, but after all it is well to be reminded that the scientific investigator is prone to take himself for granted and not to realise "what an altogether astonishing and even grotesque mystery he and his doings constitute" for the general mass of social human beings

"Co-operation and the Problem of Unemployment" is the title of a pamphlet issued last month by the Calcutta newspaper *Capital*, being a reprint of a series of articles contributed by Captain J. W Petavel, Principal of Maharajah Kasimbazar's Polytechnic Institute, together with correspondence between Captain Petavel and the Vice-Chancellor of the Calcutta University The recent establishment by this university of a Poverty Problem Study Fund, to meet the cost of lectures and publications devoted particularly to the exploitation of a definite scheme of social reform, constitutes a new departure in university policy in regard to research in applied sociology. This scheme "to organise the children and the adolescents in schools *and continuation schools*, so as to make them form the trunk of a great tree of co-operative production and exchange, whose branches will extend in all directions and carry health into every part of our social system," is not new. Among its earliest supporters were the late Lord Roberts and Sir Horace Plunkett Of late "economists and educationists in almost every part of the world," says the Vice-Chancellor of Calcutta University, have been canvassed, with the result that there has been a steadily increasing volume of opinion in favour of the scheme, and steps are being taken towards operating a large-scale trial application of it in schools in Bengal by means of self-supporting school market-gardens and school workshops The experiment cannot fail to arouse keen interest, not only in India but wherever attempts are being made to extend and improve education without increasing its cost.

Calendar of Industrial Pioneers.

August 27, 1898. John Hopkinson died.—Distinguished as an engineer and a mathematical physicist, Hopkinson was a graduate of Trinity College, Cambridge, and in 1871 was senior wrangler and Smith's prizeman. For some years he was scientific adviser to Messrs Chance, of Birmingham, and made improvements in lighthouse apparatus As a consulting engineer in London he took up the study of electrical problems, in 1882 patented the three-wire system, and four years later, with his brother Edward, published an important memoir on the principles of the design of dynamos. In 1890 he became professor of electrical engineering at King's College, London, and on two occasions served as president of the Institution of Electrical Engineers. His death was the result of an Alpine accident.

August 27, 1914. William Thomas Lewis, Lord Merthyr of Senghenydd, died.—Coal owner, iron master, steel maker, engineer, and a captain of industry, Lewis began life as an apprentice in a South Wales engineering works. In 1860 he became mining engineer to the estates of the Marquis of Bute, and twenty years later was made sole manager. He was a pioneer in the construction of steel works.

August 31, 1751. Christopher Polhem died.—A famous mining engineer of Sweden, Polhem was born in 1661, in 1693 became engineer of the mines at Fahlem, and in 1716 was raised to the nobility and was made a member of the council of mines He travelled extensively, carried out important engineering works, and was one of the original members of the Academy of Sciences of Stockholm

August 31, 1865. John George Appold died.—After amassing a considerable fortune as a fur skin dyer, Appold turned his attention to mechanical pursuits and at the Great Exhibition of 1851 attracted attention by his centrifugal pump Among his other inventions was the brake used in connexion with the laying of the first Atlantic cable.

September 2, 1834. Thomas Telford died.—The son of a shepherd of Eskdale, Dumfries, Telford was born on August 9, 1757. Apprenticed to a mason, he afterwards worked in Edinburgh, London, and Portsmouth, became surveyor of public works in Shropshire, engineer of the Ellesmere Canal, and in Scotland built the Caledonian Canal and opened up the country by the construction of 920 miles of roads and of 120 new bridges Many other bridges, canals, and harbour schemes were due to him, and among these were the Gotha Canal between the Baltic and North Sea and the famous suspension bridge over the Menai Straits An acknowledged leader in the world of civil engineering, in 1818 he became the first president of the Institution of Civil Engineers and held that position till his death He died at 24 Abingdon Street, Westminster, and was buried in the nave of Westminster Abbey. His statue stands in the Chapel of St. Andrew.

September 2, 1883. Cromwell Fleetwood Varley died.—One of the pioneers of the Atlantic Telegraph Cable, Varley as a boy entered the service of the Electric and International Telegraph Company and of this firm became engineer-in-chief. After the failure of the first Atlantic cable he constructed an experimental line for studying the phenomena of signalling, and during 1864–5 tested the whole of the new cable for the Atlantic Telegraph Company. Retiring from active work in 1868, he continued his investigations and in 1870 transmitted musical sounds over an ordinary telegraph wire. E. C. S.

Societies and Academies.

PARIS.

Academy of Sciences, July 24.—M. Haller in the chair.—Charles **Moureu**: The third international conference of pure and applied chemistry. This conference was held at Lyons from June 27 to July 1, and was attended by representatives from 24 nations. The next meeting will be held at Cambridge in June 1923.—Maurice **Leblanc**: The electrification of railways by means of high frequency alternating currents.—V. **Grignard** and A. C. **Purdy**: α-β'-dichlorethyl ether. Three of the four possible dichlorethers are known. The fourth, $CH_3.CHCl.O.CH_2.CH_2Cl$, has now been prepared by the action of dry hydrochloric acid upon a mixture of paraldehyde and ethylene monochlorhydrin.—M. **Abramesco**: The series of polynomials with two complex variables.—Farid Boulad **Bey**: The geometrical examination of the internal forces and displacements round a point in an elastic body.—Paul **Dienes**: The displacement of tensors.—Paul **Sacerdote** and Pierre **Lambert**: A new method for detecting the presence of a submarine. The plan proposed is suitable for a narrow entrance to a port and is based on the difference between the electric conductivity of the submarine and of sea water.—G. **Athanasiu**: An actinometer with electrodes of mercury covered with a thin layer of mercurous chloride, bromide, fluoride, or sulphide. A cell is constructed of H form, with mercury electrodes covered with a thin film of haloid salt. Exposure of one electrode to light causes an immediate increase in the E.M.F. of the cell.—St. **Procopiu**: The variations in the arc spectrum of mercury with the conditions of emission. In a vacuum, working at 14 to 15 volts, with low vapour pressure, there are more lines visible in the ultra-violet (up to 2191) than when working with 65 volts and 3·5 amperes. Other modifications are noted if the arc is working in air or in coal gas, the lines forming the triplets in the two secondary series being specially affected.—Mlle. Irène **Curie**: The determination of the velocity of α rays of polonium. The method of deviation in a magnetic field was employed, and this gave $1{\cdot}593 \times 10^9$ cm. per second for the velocity of the α rays of polonium, with a precision of about 0·3 per cent. Geiger, by a different method, obtained a result within 0·4 per cent. of the above.—P. **Lebeau** and M. **Picon**: The reactions furnished by sodammonium with hydrocarbons. Paraffins and ethylene derivatives are unacted upon by sodammonium: allylene gives 66 per cent. of the sodium derivative and 33 per cent. of propylene, and other hydrocarbons of the acetylene series behave similarly. Benzene and its derivatives are unacted upon, as are also the terpenes. Naphthalene, acenaphthene, and phenathrene give tetrahydrides.—Octave **Mengel**: The fall of dust called a "rain of blood." Remarks on the coloured snow which fell in Briançon on March 12, 1922. The meteorological data suggest that this dust came from the Sahara.—Emile-F. **Terroine** and René **Wurmser**: The utilisation of ternary substances in the growth of *Aspergillus niger*. This mould would appear to utilise indifferently any sugar in its growth, and shows no qualitative preference. The sugars used were glucose, levulose, saccharose, maltose, arabinose, and xylose. The concentration of the nitrogenous food (ammonium sulphate) was also without effect on the growth, but the nature of the source of nitrogen had a marked influence.—L. **Blaringhem**: The heredity of the physiological characters in the hybrids of barley (second generation):—Paul **Becquerel**: The theory of the meriphyte in the phenomena of vascular ontogeny.—A. **Pézard**: The idea of the "seuil différentiel" and progressive masculinisation of certain female birds. The experimental results relating to the action of the ovary on the plumage of birds can explain, on the hormone theory alone, some anomalies apparently in disagreement with recent theories of endocrinology.—Paul **Wintrebert**: The mode of building of the vomer in the course of metamorphosis in the Salamandridæ.—Paul **Carnot** and Marc **Tiffeneau**: A new hypnotic in the barbituric series: butyl-ethyl-malonylurea. The hypnotic properties of the dialkyl-malonylureas were studied by E. Fischer from dimethyl to the di-isoamyl derivative, but the unsymmetrically substituted malonylureas were not examined. This has been taken up by the authors, who find in ethyl-butyl-malonylurea a useful new hypnotic. It has three times the hypnotic power of veronal and has given satisfactory results in clinical practice.

July 31.—M. Guignard in the chair.—The president announced the death of M. Louis Favé.—Emile **Picard**: The meeting of the International Research Council held at Brussels in July 1922. The address given by M. Picard at the opening of the meeting.—L. **Maquenne** and E. **Demoussy**: The influence of calcium on the utilisation of the reserves during the germination of seeds. It has been shown that the influence of calcium on the germination of seeds is specific, and other electrolytes do not produce the same effect. Calcium salts are almost without influence on the diastatic conversion of the insoluble reserves into soluble products; it is possible, but not yet proved, that the ferments responsible for the reconversion of the soluble products into plant tissue may be stimulated by the presence of lime.—R. **Chodat** and E. **Rouge**: The intracellular localisation of an oxydase and localisation in general.—Jules **Baillaud**: Some data on the constitution of the galactic cluster deduced from the study of the zone of the Paris photographic catalogue.—Jean G. **Popesco**: The relation between photo-electric phenomena and the surface tension of mercury. The surface tension of an electrically charged drop of mercury was measured by a photographic method before and after exposure to ultra-violet light. The results of the experiments show that there is a relation between the photo-electric phenomenon and the surface tension.—E. M. **Lémeray**: The structure of the universe and general relativity.—R. de **Mallemann**: Molecular double refraction and optical activity.—M. **Yovanovitch** and Mlle. **Chamié**: The preparation of a standard radium salt. A solution of barium chloride containing radium is precipitated by ammonium carbonate in a special apparatus due to M. Jolibois. The radiferous barium carbonate produced was fairly satisfactory as a standard, different preparations agreeing in their radioactive properties within 0·5 per cent.—Er. **Toporescu**: The preparation of sodium bicarbonate.—Mlle. G. **Marchal**: The dissociation of beryllium sulphate. The dissociation pressures are given for seventeen temperatures ranging from 590° C. to 830° C.—Maurice **François** and Louis Gaston **Blanc**: A method of preparing the iodobismuthates of the alkaloids in the crystalline state.—H. **Gault** and T. **Salomon**: The alkyl-methyl-pyridazinone carboxylic esters.—G. **Vavon** and A. **Husson**: Catalysis by platinum black. Platinum black may have its hydrogenating power reduced by the gradual addition of catalyst "poison," such as carbon bisulphide. Thus the activity of a certain specimen of platinum black, after treatment with 0·4 mgr. of carbon bisulphide, lost the power of reducing acetophenone, but retained its catalytic power as regards the reduction of cyclohexene.—Kenneth C. **Bailey**: The direct synthesis of

urea starting with carbon dioxide and ammonia. Applying the device of the hot and cold tube, carbon dioxide in presence of ammonia in excess and with thoria as catalyst, gave a 19 per cent. conversion into urea.—M **Gignoux** and P. **Fallot**. The marine Pliocene on the Mediterranean coasts of Spain.—A **Guilliermond** Remarks on the formation of chloroplasts in the bud of *Elodea canadensis*.—G **André**. The filtration of plant juices Comparative analyses of juice expressed from the potato, after clarification by the centrifuge, filtration through porous porcelain filter, and filtration through collodion. In the last case, the proportions of nitrogen and phosphorus present are reduced—Gabriel **Bertrand** and B **Benzon**: The importance of zinc in the food of animals. Experiments on mice.—H **Vallée** and H **Carré**: The degree of infection of aphthous fever.—Georges **Bourguignon** Double chronaxy and a double motor point in certain human muscles

SYDNEY

Linnean Society of New South Wales, June 28.—Mr. G A Waterhouse, president, in the chair W. F **Blakely**: The Loranthaceæ of Australia, Part ii A revised classification of the Loranthaceæ, based on that of Engler, is put forward. The most notable changes in the nomenclature affect the genus Atkinsonia which is displaced by Gaiadendron, while the species under Loranthus, with versatile anthers, are transferred to Phrygilanthus.—Dr R J **Tillyard**: Some New Permian Insects from Belmont, N S W, in the collection of Mr. John Mitchell Nearly half the insect wings discovered at Belmont belong to the family Permochoristidæ In association with these are two other Mecopteroid types, viz, Belmontia and a new type, described in this paper, which stands in the same relation to the Order Diptera that Belmontia does to the Trichoptera and Lepidoptera In addition the first discovery of a true Lacewing (Neuroptera, Planipennia) of Palæozoic times is recorded The remainder of the fauna consists of Homoptera, both Auchenorrhyncha and Sternorrhyncha, a new genus of the latter being described.—J **Mitchell**: A new Gasteropod (fam Euomphalidæ) from the Lower Marine Series of New South Wales Description of a new species of Platyschisma from Allandale, where it occurs associated with *P oculus*, *Eurydesma cordatum*, and *Aviculopecten mitchelli*.—**Vera Irwin-Smith**: Notes on Nematodes of the genus Physaloptera. Part iii. The Physaloptera of Australian Lizards. This paper deals with specimens of Physaloptera contained in three collections They were found to consist of two forms, one of which has been identified as *P antarctica* Linstow var *typica* The other has been treated as a new variety of the same species Linstow's brief and inadequate diagnosis of the species has been supplemented by a detailed description. The rest of the paper is devoted to a special study of the female reproductive organs, in which it is pointed out that the practice of helminthologists of basing specific distinctions, in this group, upon the dimensions and arrangement of these parts is not reliable, since very considerable variations have been found within the one species.—J. **McLuckie**: Studies in Symbiosis i The Mycorhiza of *Dipodium punctatum* R Br

Royal Society of New South Wales, July 5 Mr C. A. Sussmilch, president, in the chair A R **Penfold**: Observations respecting some essential oils from *Leptospermum Liversidgei*. The variation in the essential oils obtained from a well-known Tea Tree (*Leptospermum Liversidgei*) is tabulated as follows:—

	Yield	Specific Gravity 15° C.	Optical Rotation	Refractive Index	Solubility in 70 per cent. Alcohol	Citral.	Citronellal	
	Per cent					Per cent	Per cent.	
No 1	0 8	0 8960	+ 6 2°	1 4854	1 in 1 5 vols	75	.	type "*b*"
No 2	0 5						70	type "*c*"
No 3	0 25	0 8885	+12 10°	1 4822	insol 10 vols	46		type "*a*"
No 4	0 33	0 8905	+12 75°	1 4820	ditto	46	.	type "*a*"
No 5	0 55	0 8826	+11 2°	1 4603	1 in 1 5 vols		82	type "*c*"
No 6	0 6	0 8910	+ 7 25°	1 4832	ditto	70	.	type "*b*"

The author is inclined to the opinion that there are probably three forms of this shrub, and points out that the types "*b*" and "*c*" are of great economic importance. The type "*a*" (the original one) is of very little commercial value, hence the importance of the other types, particularly as botanical diagnosis has so far failed to distinguish them.—A R **Penfold** and F. R **Morrison** Preliminary note on a new Stearoptene (probably a phenol ether) occurring in some essential oils of the Myrtaceæ The authors announced the isolation of a beautifully crystalline solid of a yellow colour from the essential oils of *Bæckea crenulata* and *Darwinia grandiflora* It has a melting-point of 103-104° C, molecular formula $C_{13}H_{18}O_4$, and contains two methoxy groups It is apparently a phenol ether It has, so far, only been obtained in small quantity, amounting to 6 per cent in the former, and 2 per cent in the latter oils, but it is anticipated that other essential oils at present being investigated will yield it in greater amount.—J K. **Taylor**: A chemical and bacteriological study of a typical wheat soil of New South Wales Monthly determinations of soil moisture, bacterial numbers, nitrates, and nitrifying power were made in soil from various plots at Wagga Experiment Farm The bacterial numbers, nitrates and nitrifying power were greater in summer than in winter in spite of the partial drying out of the soil The general order of merit of the plots for bacterial activity and accumulation of nitrates was cultivated fallow, cropped land, uncultivated fallow, and grass land The bacterial numbers are comparable with those from soils from similar climatic regions but the nitrifying power is not particularly good and fluctuated curiously from month to month.

Children and Museums.

THE direct educational work accomplished by museums in the United States is a perpetual source of shame to us in this country. We are well aware that much is being done in some of our own museums, often at the self-sacrifice of their officials; but have we anything to compare with what is described in a recent number of *Natural History* (March-April 1922)—the journal of the American Museum of Natural History? Consider lantern-slides, for example. Our own Natural History Museum has recently started one or two loan collections, comprising in all some few dozen slides. Those of the American Museum number many thousands. They are stored in a room accessible to teachers, who can thus select precisely what they want for their class-room lectures. Last year more than two hundred thousand slides were circulated. It is not long since a fair collection of slides made by an assistant in our own museum was handed over to another institution because there were no facilities for keeping it in the museum itself. Needless to say, the American Museum has a lecture theatre. It has 869 nature-study collections to be lent to any public school in greater New York. There are two motor cars and a motor cycle to deliver slides and collections. Each messenger visits from twenty to forty schools a day. The American Museum is about to erect a special School Service building of five storeys where from three to five thousand children daily may be taken care of properly. The blind are also provided for.

Of course, all this cannot be done by the ordinary officers of the museum, and that is a fact which must be recognised in this country. The American Museum has its own Department of Education, with Mr. George H. Sherwood at the head. In the same way the Brooklyn Botanical Garden has its Curator of Elementary Education, who contributes to the same issue of *Natural History* an interesting article on "Gardening and the City Child." But the work which starts in the museums and public gardens of New York and Brooklyn is taken up by other outside bodies, as the School Nature League of New York City, the president of which, Mrs. John I. Northrop, here tells us how in one of the elementary schools in the middle of the slums a wonderful nature-room has been installed. It is visited by from eight hundred to one thousand children every week. Here is a place for all those miscellaneous curiosities so frequently rejected by the staid museums. They can be placed in the hands of the children and many a fascinating lesson drawn from them. The love of nature thus begun is carried out into the open by means of summer camps,

and so becomes linked up with the Boy Scout camps with their travelling museums.

Well, why is it that the Americans have got so far ahead of us on these lines? They have no doubt a new field to cultivate, and they do not have to contend against the terrible weight of inertia inevitable to some of our royal and ancient establishments. But to a large extent it is because Americans are not ashamed of having an ideal and of talking about it. They do not mind saying what they are going to do, and they make the utmost of everything that they have done. This is not the Englishman's way, but it is a way that interests the public both rich and poor. It brings money from the former and enthusiasm from the latter. If we want to achieve the same results we must not be above following somewhat similar methods. Here, during the summer holidays, are the children crowding our museums at South Kensington day after day. Cannot something more be done for them, even if we shed a little dignity in the process?

Ninety Years of British Science.

The British Association for the Advancement of Science: A Retrospect, 1831–1921. By O. J. R. Howarth. Pp. vii+318. (London: British Association, Burlington House, 1922.) 7s 6d.

MR. HOWARTH is to be congratulated on the manner in which he has used his opportunity, while the record he has produced is a most ample justification of the title of the Association—the British Association for the Advancement of Science—British in that its meetings have been held in nearly every part of the Empire, India excepted; and perhaps, as the part India can play in advancing science is more fully recognised, we may in the years to come have a meeting at Delhi, the centre of a civilisation dating back centuries before the Association.

The work is due to a suggestion made by Sir Charles Parsons when president in 1919–20, and owes much to his generous support, while the author has been helped in his task by many friends whose assistance is gratefully acknowledged in the preface. Commencing with the history of the foundation of the Association in 1831, the work deals with its relation to the advancement of science, its organisation and meetings, its aid to research, its connexion with the State, and its work overseas. The author states that his aim has been "to provide a summary review of its activities, with examples," and this he has done with conspicuous success.

Founded in 1831, the Association's life of ninety years has been full of stirring events. Sir David Brewster was its founder; in the *Edinburgh Journal of Science* (vol. 5, 1831) he wrote: "Some months ago it occurred to the editor of this work [himself] that the general interests of science might be greatly promoted by the establishment of a Society of British Cultivators of Science which should meet annually in some central town in England." In writing this Brewster had in mind the work of the *Deutscher Naturforscher Versammlung*, about which an article had appeared in the preceding volume of the journal. The objects of the meeting of this society were, as the author of this article stated, to promote "acquaintance and friendly personal intercourse among men of science; but other great and more important benefits grow out of them." "Might not," he continued, "similar results in our older country be looked for from a similar institution." This statement sums up the work of the Association. Similar results have followed, but to an extent undreamt of by Brewster and his colleagues. The first meeting was held at York. Dalton was there—"old Dalton, atomic Dalton, reading," as Murchison wrote later, "his own memoir, and replying with straightforward pertinacity to every objection in the highly instructive conversations which followed each paper."

Ninety years later the atom has been resolved into its constituent electrons, and Thomson, Rutherford, and Bohr have stated in no uncertain terms the laws which govern the planetary system of the atom, atom no longer when subject to the bombardment of the swift-moving electrons of the cathode rays.

The second meeting of the Association was held at Oxford, and the third at Cambridge. Sedgwick was president, and Mr. Howarth has printed an interesting selection of autographs of members present—Brewster Airy, Babbage, Faraday, Forbes, Herschel, Buckland, Harcourt, Murchison, Phillips, Peacock, Rigaud, Sedgwick, Whewell, Houston, etc., all great names; the physical sciences predominate. Biology was not, or rather it was represented by a little natural history, with some botany and geology. Of the Oxford meeting Murchison, afterwards general secretary and (1846) president, wrote that "under the presidency of Buckland, the body was licked into shape and divided into six sections."

Started thus under brilliant auspices, the Association has been a potent factor in the advancement of science; in its earlier years, it is true, it met with criticism and ridicule in some quarters—Dickens's "Mudfog Papers" may be mentioned; these it has outlived, and the striking success of the Edinburgh Meeting of 1921 showed that even in the altered conditions of the twentieth century there is still ample work for it to undertake.

Turning now to a brief reference to its numerous

activities, from the commencement these have not been confined to the period of its annual meetings, and its main contributions to the advancement of science have been through the work of its various committees, aided by grants from its funds, and through the reports on the state of some special science drawn up by a member deputed for this work. "We repudiate," wrote Murchison in 1845, "that the chief aim of our existence is to stir up a few embers of scientific warmth in the provinces," and Owen, president in 1858, claimed that the association was realising the dream of Francis Bacon recounted in his "New Atlantis" Whewell in 1862 wrote: "The Association wants money and ought to get it for it spends a great deal," he might have added, on objects of the utmost importance to the welfare and progress of mankind.

Mr Howarth has given in an Appendix a complete list of the grants for research.

The following is a summary of these:

Section	*l*	*s*	*d.*
A (Mathematics and Physics)	34,977	18	7
B (Chemistry)	4,178	17	8
C (Geology)	6,956	3	11
D (Zoology) and K (Botany) jointly	1,579	1	10
D (Zoology)	12,093	15	5
E (Geography)	3,695	13	4
F (Economics)	1,322	4	3
G (Engineering)	4,164	7	6
H (Anthropology)	7,226	16	11
I (Physiology)	3,115	13	7
K (Botany)	1,952	15	1
L (Education: founded in 1901)	538	18	6
M (Agriculture: founded in 1912)	5	0	0

The total sum expended since 1834 has been about 83,000*l.*, somewhat less than 1000*l.* a year it is true, but no inconsiderable sum when it is remembered it has been raised almost entirely from the subscriptions of its members, in the main men and women of science themselves.

The attempt to give details of the researches promoted by these grants would occupy far too much space An interesting account will be found in Mr. Howarth's pages. Reference may, however, be permitted to a few taken from the list for Section A. Between the years 1862 and 1910 about 1100*l.* was spent in establishing electrical standards, which are now adopted throughout the world and have formed the foundation on which the whole edifice of applied electricity is reared. The observatory at Kew was supported from 1843 to 1872 in great measure by grants of more than 12,000*l.*, and for many years, by the issue of accurate standards and in other ways, promoted in a marked degree meteorological science. Under the subject Heat we find "Remeasurement of dynamical equivalent, 1870–80, 106*l.* 0*s.* 6*d.*"; Joule's work was thus supported by the Association. Seismology has been aided to the extent of more than 2500*l.*, while grants to tidal observations have reached about the same sum. Similarly, from the other Sections examples might be given, showing the influence the Association has exerted on progress and the value and wide scope of its work. For ninety years the Association has laboured, a union of voluntary workers for the advancement of science. In the words of Rayleigh, president in 1884, "The work may be hard and the discipline severe, but the interest never fails, and great is the privilege of achievement" Of the achievements of the Association Mr Howarth's book is a fitting record.

A Standard Treatise on Crystallography.

Crystallography and Practical Crystal Measurement. By Dr. A. E. H. Tutton. Second edition In 2 vols. Vol. 1: *Form and Structure.* Pp. xvii + 746 + xiv. Vol. 2: *Physical and Chemical.* Pp viii + 747–1446. (London: Macmillan and Co, Ltd., 1922.) 50*s.* net each.

THE eleven years which have elapsed since the first edition of this work appeared, have witnessed a remarkable and welcome increase in the interest taken in crystals by chemists and physicists. On the chemical side this has been due partly to the efforts made by Pope and Barlow to correlate chemical composition and crystalline form, and partly to the tardy recognition on the part of organic chemists that the crystal form and optical properties of a substance, once accurately determined, form the most valuable means of identifying it that we possess On the physical side interest has been aroused by the remarkable discovery of Laue and his collaborators that the conception of a crystal as an orderly arrangement of very minute particles arrived at by the experimental study of crystal morphology, and also from purely geometrical considerations, had a solid basis in fact and could be demonstrated by the diffraction of Rontgen rays. In the hands of the Braggs and of others working on similar lines, this discovery has led to a very wonderful increase in our knowledge of crystal structure. It is natural that these advances should be reflected in the work before us, and we find accordingly that Dr. Tutton has found it necessary to employ nearly five hundred additional pages to deal with the wealth of matter the past ten years have provided.

This has necessitated the division of the work into two volumes, each consisting of two sections, and has also led to a certain amount of re-arrangement of the material contained in the first edition. The first section, which occupies nearly one-third of the whole work, deals with crystal measurement by means of

the one-circle, horizontal, reflecting goniometer, and follows closely on the lines of the original edition. A useful account of methods of goniometry at low temperatures has been introduced, and the use of the two- and three-circle goniometers, and the methods based on the gnomonic projection and associated with the name of V. Goldschmidt, receive more adequate treatment than before. The student will, however, miss in this chapter the extraordinarily detailed description of every step in experiment and in computation to which Dr. Tutton has accustomed him in what has gone before, and when he finds that three hundred pages are devoted to the discussion of one-circle goniometry the enthusiast for two-circle methods will scarcely perhaps feel content with part of one chapter. Many readers will wish for fuller information as to the methods of drawing crystals devised by Penfield and by Goldschmidt, and would have welcomed some account of the ideas on "complication" developed by the latter.

The second half of the first volume deals with crystal structure and X-ray analysis and contains much new matter. In particular, attention may be directed to the well-illustrated and concise account of the Sohncke point systems and also to the useful table of the 230 space groups, which will be found helpful as an introduction to a somewhat inaccessible part of the subject. Dr. Tutton's treatment arouses the wish that he had used his powers of clear exposition to elucidate still further these difficult but very important matters. The chapter on the application of X-rays to the determination of crystal structure gives an admirable account of the progress that has been made, while the sketch of Fedorov's views on the correct setting of crystals and on the compilation of a dictionary of crystal forms to facilitate the identification of chemical compounds by their morphology alone, whets our curiosity, and leads us to wish that Dr Tutton had shown us how to work out the reticular density and the correct setting in a few typical cases.

The third section deals in the main with crystal optics, and begins with an introductory chapter which contains readable accounts of matters so diverse as thermionic valves, radio-activity, atomic numbers, isotopes, theories of atomic structure, the Zeeman effect, Aston's positive ray mass spectrograph, the Michelson echelon, and the Lummer-Gehrcke plate. The succeeding chapters are in the main reprinted from the first edition, but the treatment of the modes of production of monochromatic light is fuller and includes a useful description of the mercury vapour lamp. When explaining the colour effects observed when thin crystalline plates are placed between crossed Nicols, Dr. Tutton says: "The Nicol analyser itself introduces, when crossed to the polarising Nicol, a change of phase of half a wave-length, like the act of reflection in the case of thin films, and this $\lambda/2$ requires to be added to the retardation of one ray behind the other brought about in traversing the crystal." Experience has shown that this statement is a source of perplexity to the average student, and it is to be regretted that Dr. Tutton has not followed the more readily intelligible treatment adopted by Groth in the successive editions of his "Physikalische Krystallographie"

The general excellence of the illustrations is so high that the figures explanatory of the use of the mica plate in finding the optical sign of crystals seem scarcely to come up to the standard. A photograph of the phenomenon reproduced as a plate would have been more in keeping with the style of the book. The figures and descriptions of polarimeters for finding the optical rotation of liquids take up valuable space and seem scarcely necessary in a work on crystallography; indeed, the connexion of much of the matter in this section with crystals is somewhat remote, although the reader will perhaps forgive the author its introduction for the sake of its intrinsic interest, a case in point being the account of the use of the barium platinocyanide screen for secret signalling during the war. The last two chapters of this section contain a full description of the various types of microscopes and of the principal methods employed in the microscopic examination of crystals, both when isolated, or when occurring in rock slices.

The concluding portion of the book opens with an excellent discussion of isomorphism, isogonism, polymorphism, and enantiomorphism, which may be especially commended to the notice of chemists, who will find therein much interesting information as to recent work not easily accessible elsewhere. The next chapters are devoted to the thermal and elastic properties of crystals, and in particular to full descriptions of the ingenious and elaborate apparatus devised by Dr. Tutton for measuring them, and to these have been appended somewhat irrelevant accounts of the Interferential Comparator for standards of length, the Michelson Interferometer, and the Etalon of Fabry and Perot. The final chapters of the book are devoted to the consideration of the electric and magnetic properties of crystals, and to a brief but sufficient account of so-called "liquid crystals"

It will be seen, then, that these two volumes are a mine of accurate information on matters belonging to a wide field of knowledge, and testify alike to the learning and industry of the author and to the enterprise of his publishers. The wealth of detail of many of the descriptions, the large number and excellence of the illustrations, and the considerable amount of irrelevant

matter introduced have naturally made the book both bulky and expensive to produce. It is to be feared that the consequent high price will place it out of the reach of the ordinary student, to whom, if we may judge by the long section on one-circle goniometry, it would seem mainly to be addressed. Had Dr. Tutton resisted the temptation to figure and describe every piece of elaborate and expensive apparatus which aroused his interest, and had he omitted all the paragraphs which have nothing to do with crystals, the length and cost of the book might have been very considerably reduced, and its accessibility to the student thereby increased, without in the least diminishing its value as a compendium of all that is worth knowing about crystal measurement as practised to-day.

New Editions of Chemical Works.

(1) *A Dictionary of Applied Chemistry.* By Sir Edward Thorpe. Vol. 3. Revised and enlarged edition. Explosives—Kyrofin. Pp. viii + 735. (London: Longmans, Green and Co., 1922.) 3*l* net.

(2) *Metallography.* By Prof. Cecil H. Desch. (Text-Books of Physical Chemistry.) Third edition. Pp. xi + 440. (London: Longmans, Green and Co., 1922.) 16*s.* net.

(3) *A Concise History of Chemistry.* By Dr. T. P. Hilditch. Second edition, revised. Pp. xi+276. (London: Methuen and Co., Ltd., 1922.) 6*s.*

(4) *An Introduction to the Principles of Physical Chemistry from the Standpoint of Modern Atomistics and Thermodynamics.* By Prof. E. W. Washburn. Second edition, revised, enlarged, and reset. Pp. xxviii+518. (New York and London: McGraw-Hill Book Co., Inc., 1921.) 20*s.* net.

(5) *Die Wasserstoffionen-Konzentration: ihre Bedeutung für die Biologie und die Methoden ihrer Messung.* Von Prof. Dr. Leonor Michaelis. (Monographien aus dem Gesamtgebiet der Physiologie der Pflanzen und der Tiere, Band I.) Zweite, völlig umgearbeitete Auflage. Teil 1: Die theoretischen Grundlagen. Pp. xi+262. (Berlin: J. Springer, 1922.) Germany, 69 marks; England, 8*s.* 6*d.*

THE reviewing of new editions is a difficult and somewhat thankless task, if only on account of the detailed comparison which is needed in order to discover the novel features which alone call for comment or criticism. The four works in English of which new editions are here noted are all well known, and it would be superfluous to refer to their obvious merits, except in so far as they have been enhanced by the revision which they have undergone.

(1) The first two volumes of the new edition of the "Dictionary of Applied Chemistry" have received adequate notice in these columns. The third volume covers the letters F to K, but begins with an article on "Explosives," which has obviously been carried over from the preceding volume on account of its length and importance. In revising this article Mr. Perry has expanded it to nearly 100 pages by including notes on a large number of new explosives which have come into use during the last few years. The article thus continues to fulfil in its own field the main purpose for which a dictionary exists, namely, to provide some information in reference to every topic which may give rise to inquiry. The main lines of development of the manufacture on a very large scale of a few principal explosives during the war are, however, also adequately dealt with, and useful information is given on points such as the preparation, purification, and properties of T.N.T., and its use in the manufacture of amatol. The portion of the dictionary which is included in the present volume has been expanded by nearly one-quarter from 602 to 735 pages, and a somewhat careful comparison of the old and new editions has shown that, almost without exception, each of the important articles has contributed to this expansion. Fresh features of the new edition include an article on the interferometer by H. H. Robinson, and an article on hardened or hydrogenated oils by C. A. Mitchell, while gas warfare forms the subject of a short unsigned article. A completely new article on glass, by Prof. W. E. S. Turner of Sheffield, has replaced the article on the same subject which appeared in the old edition; the illustrations given in the new article of the automatic machines used for the manufacture of bottles are remarkable as suggesting something even more complex than the engine-room of a submarine. Throughout the volume there is evidence of adequate revision, which fully justifies the issue of the new edition.

(2) The third edition of Prof. C. H. Desch's "Metallography" retains all the valuable features on which the reputation of the book has been built. Substantial additions have been made in the chapter on the physical properties of alloys, where important developments which had taken place since 1913, especially in the study of magnetic and electrical properties, are described. Additions have also been made to the chapter on corrosion, in which the recent work by Dr. J. N. Friend in the Journal of the Chemical Society, is now incorporated, together with other work which has appeared in the Journal of the Institute of Metals and the Transactions of the Faraday Society, where a general discussion on this subject is reported. The chapter on the metallography of iron and steel has also been revised, one important new feature being an equilibrium diagram for iron and nickel, in which the changes that take place in the solid metal as it passes

from the non-magnetic into the magnetic condition are represented by lines, which show the formation of a definite series of solid solutions, instead of by blurred areas. The appendix, in which the various binary, ternary, and quaternary systems which have been studied are classified and summarised, has been revised to include publications received down to the time of going to press. The new edition incorporates the results of nine years of work in metallography, and it can be heartily commended for its up-to-date presentation of this important subject.

(3) The first edition of Dr. Hilditch's "Concise History of Chemistry" was reviewed in NATURE of October 19, 1911, p. 510. The new edition has been expanded from 263 to 276 pages, and, in view of the number of additional topics that have come into prominence during the past ten years, it is clear that the conciseness of the old edition has been at least fully maintained in the new. It will thus be found that the nucleus atom, X-ray analysis of crystals, Moseley's atomic numbers, the octet theory of Langmuir and the discovery of isotopes, are all described in the course of three pages in the chapter on the "Ultimate Constitution of Matter," although another page is given later on to some of these subjects. Gas warfare is described in a paragraph of eleven lines, and "anti-gas" is summed up in a paragraph of four lines. In a few details only the revision is perhaps incomplete, *e.g.* the list of the metals of the rare earths is still that of 1909, with holmium omitted, and the atomic weights (which are of the same date) might well have been supplemented by giving also the atomic numbers; moreover, the new matter is by no means fully represented in the subject index, although the author-index appears to have been revised. The value of the book as an index of chemical discoveries is preserved in the new edition, although it would obviously be useless to look for detailed descriptions in so compact a volume.

(4) Prof. Washburn's "Principles of Physical Chemistry" was reviewed in these columns on June 1, 1916, p. 277, and has established a wide reputation in this country as well as in the country of its origin. As the first edition appeared but seven years ago, only those subjects which have developed since the war have called for further elaboration. These include, however, the work of Aston on isotopes and all the recent work on atomic and molecular structure. It is, indeed, remarkable evidence of the rapid progress which has been made in this field that, while the first edition stops with an account of the qualitative aspects of the periodic classification, and of the models which Soddy and Harkins put forward in order to explain the sequence of properties, these two figures have disappeared in the second edition in favour of a large chart illustrating the Lewis-Langmuir theory; and this chart in turn is probably already obsolete in view of the suggestions put forward by Bohr for making use of the quantum-orbits of the electrons as a basis for the periodic classification of the elements. The work on the X-ray analysis of crystal-structure, which was briefly mentioned in the first edition, claims eight pages in the second edition. Anisotropic liquids are, however, inadequately (and perhaps incorrectly) dealt with, especially in view of recent French work on this subject.

(5) Dr. Michaelis's book on "Hydrogen Ion Concentration" was first issued in 1914. The present volume is a new edition of the first and theoretical part of the book, and covers two main topics, namely, the chemical equilibrium of ions and ions as sources of differences of electrical potential. The subject has attracted even more attention from physiologists than from chemists, and Dr. Michaelis's book is actually issued as the first volume of the series of monographs on physiology; but this does not detract from its value to physical chemists, and especially to those who are liable to be called upon to answer the conundrums of their biochemical colleagues.

Phosphatic Fertilisers.

Basic Slags and Rock Phosphates. By Dr. G. Scott Robertson. (Cambridge Agricultural Monographs.) Pp. xvi+120. (Cambridge: At the University Press, 1922.) 14s. net.

DURING and since the war the position in this country with regard to the supply of basic phosphatic fertilisers has undergone a radical change. On one hand, the ousting of the older Bessemer process by the modern open hearth process of steel-making has led to the virtual disappearance from the market of the high grade basic slag to which the agriculturist was accustomed, and its replacement by a totally different material of much lower phosphorus content and frequently of low "citric-solubility." On the other hand, the development of the extensive deposits of rock phosphate in the Pacific Islands has rendered available greatly increased amounts of this material. The field experiments at Cockle Park, from which most of our knowledge of the value of basic slag in agriculture was derived, were carried out with the now obsolete high grade Bessemer material, and prior to Dr. Robertson's experiments practically nothing was known as to the fertilising value of the new open hearth slags; the experiments in this country on raw rock phosphate were also few in number and not very conclusive in result.

Dr. Scott Robertson's experiments were carried out on several different farms in various parts of Essex during the years 1915–20, and were designed to test the relative fertilising value of Bessemer and open hearth basic slag, and of mineral phosphates, on permanent grassland cut for hay. The results of these experiments form one of the most important contributions which have been made in recent years to the literature of phosphatic manures, and their publication in book form is thus very welcome. It was found that on heavy soils of the London Clay and Boulder Clay the improvement effected by rock phosphates compared favourably with that due to high-soluble basic slags, especially in a wet season when the hay harvest was late, and on sour soils. The low-soluble fluorspar slags were definitely inferior, though still effecting a considerable improvement. At two of the centres where the experiments were carried out there was no response to phosphatic manuring, and the author produces evidence that this is due to the operation of another limiting factor, probably deficiency of potash. This point is of interest in connexion with the fact, well known to agriculturists, that basic slag is not invariably effective on all grassland. It is quite likely that some, at least, of these failures are due to a similar cause.

Dr. Robertson did not restrict his work to the determination of the yields of hay on his plots. He presents interesting data on the botanical composition of the herbage, and on the effect of the phosphatic manures on such soil factors as moisture content, temperature, total nitrogen and nitrate content, bacterial numbers, and acidity, all of which, together with climate conditions, are considered in relation to their possible influence on the yields obtained.

Needless to say, the book is well printed and produced, but the price is high for a small volume and will certainly react unfavourably on its sale. This is regrettable, for it deserves a wide circulation among all interested in the improvement of our grasslands and in the country's agricultural production.

H. J. P.

Our Bookshelf.

(1) *Potash.* By Sydney J. Johnstone. New edition revised and enlarged. (Imperial Institute. Monographs on Mineral Resources, with special reference to the British Empire.) Pp. x+122. (London: John Murray, 1922.) 6s. net.
(2) *Oil Shales.* By Dr. H. B. Cronshaw. (*Ibid.*) Pp. x+80. (London: John Murray, 1921.) 5s. net.

(1) MR. S. J. JOHNSTONE'S monograph on sources of potash is the most useful summary that has been produced since that written by Messrs. H. S. Gale and W. B. Hicks for the Geological Survey of the United States ("Potash in 1917," published 1919). It has no index, but ends with an excellent bibliography, arranged in the sequence of references to the papers in the text. The author deals with all commercial sources of potash, including (p. 112) the product styled Karroo ash, a residue from the ignition of the sheep-dung used as fuel in the Karroo region of S. Africa. The attention now given to alunite is well reflected in the summaries on pp. 51 to 60. The methods of treatment are described, and it may be remembered that a research by W. T. Schaller, the mineralogist, led to the suggestion of the simultaneous extraction from alunite of potash and alumina for commercial purposes. The nomenclature in the analyses of products from the Alsatian mines on p. 12 does not agree with that adopted elsewhere in the text, and the use of "kainite," here and on p. 5, as a synonym for "sylvinite" is an obvious error. "Sylvinite" is, of course, a trade-name for a mixture of sylvine and rock-salt. It is surely time that "muriate of potash," as a name for a substance containing no potash, disappeared. On p. 5 the potassium-content of various products is given, calculated as potash, and the German and other salts are quoted as yielding 100 per cent. We believe that 12·4 per cent. was the official figure adopted by the German Potash Syndicate in 1921. The account of the occurrences of the ordinary soluble potassium salts seems the least satisfactory part of the present memoir. What, for instance, is meant (p. 11) by "the amount of potash averages 30 per cent. of potassium chloride" in the description of an Alsatian deposit?

(2) Dr. Cronshaw's review of oil-shale resources is valuable as a record of attempts to locate such shales by boring in England. Something seems to have gone astray in the account of the Ballycastle coalfield (p. 28), where the Scottish "Broxburn shale" and a place called "Newlygen" are introduced. The description of explorations and results in other countries shows how comparatively successful the industry has been in south-eastern Scotland, though even here the refineries are now to be supplied with imported oil. The author provides a good general and local bibliography.

G. A. J. C.

Town Theory and Practice. By W. R. Lethaby, G. L. Pepler, Sir T. G. Chambers, R. Unwin, and R. L. Reiss. Edited, with an Introduction, by C. B. Purdom. Pp. 139. (London: Benn Bros., Ltd., 1921.) 5s. net.

MR. PURDOM points out that, notwithstanding the frequent mention of "garden-cities" in the popular press, it is not generally understood that it is a technical term denoting a self-contained area set out upon a definite plan and including within its boundaries all the requisite elements for the life of an independent community, and that Letchworth and Welwyn alone conform to this definition. This little book on the theory and practice of the garden-city contains five essays which deal with various aspects of the question. Mr. W. R. Lethaby deals with the town itself in an essay of a general character; Mr. G. L. Pepler describes the town plan, showing how the garden-city endeavours to combine practical utility, the convenience of the workers and business undertakings, and æsthetic and hygienic considerations, and Mr. Raymond Unwin, in

discussing the best size of the town for good social life, considers among other matters, the bearing of the number of the population upon the question of educational facilities and artistic development, such as music and the drama. Mr Reiss raises some interesting points in connexion with land values and the possibility of co-operation with local authorities in the matter of rating and the development of municipal activities. For the use of those who wish to pursue the subject further, a bibliography is appended.

Land and Sea Speed Reckoner. Designed by Capt. W. N. McClean. (London: Constructed by C. T. Cooper and Sons, Ltd.) *1l. 12s. 6d.*

THIS is an instrument of the slide-rule type, which has of late years met with considerable favour among navigators for dealing with that class of problem in which an approximate solution is sufficient. By means of the instrument it is possible to obtain (1) speed, when distance and elapsed time are known; (2) elapsed time, when speed and distance are known; (3) distance, when elapsed time and speed are known. The slide-rule consists of two scales, namely, (*a*) a time scale, styled the "Slider," and (*b*) a distance scale, and by setting these in correct mutual relation any of the above problems can be dealt with in one simple operation. Thus, if elapsed time is $8^m\ 40^s$, while distance steamed is 3·2 miles, all that is necessary is to bring the graduations denoting these two values vertically opposite to each other, when the required speed, in this case 22·2 miles per hour, is read off on the distance scale, opposite the division on the time scale marked one hour.

A modification of the instrument, known as the "Air Speed Reckoner," has a specially adapted distance scale to meet the case of high speeds in the navigation of the air.

The manipulation of the scales is simple, and easy to grasp, and the invention seems well adapted to the purpose of dispensing with troublesome arithmetical calculations which the designer appears to have had in view.

Diet and Race: Anthropological Essays. By F. P. Armitage. Pp. vi + 144. (London: Longmans, Green and Co., 1922.) *7s. 6d.* net.

MR. ARMITAGE discusses the relation of diet to stature, pigmentation, and head form. In reference to stature, after an analysis of the food values of staple articles of food in different parts of the world, he suggests that each is associated with a particular type of physique, and shows that scarcity of food is a concomitant of diminutive stature, and *vice versa*. In dealing with pigmentation, he shows that pigmentation varies with the amount of salt which enters directly or indirectly into the diet, the greatest quantity being consumed by the fairer races. The question of pigmentation is obscure, and although it is generally regarded as due to environment, it is not clear how variation has been brought about. It is not impossible that the chemical action set up by salt may be one of the factors involved. In regard to head form, the author suggests that the difference between long and broad heads may be due to the difference of muscular effort requisite in masticating soft and hard foods. The author does not appear to be aware that a similar suggestion, both as to the effect of muscular action and as to the character of food, was put forward by Prof. Arthur Thomson some years ago.

Introduction à l'étude des fonctions elliptiques à l'usage des étudiants des facultés des sciences. Par Prof. P. Humbert. Pp. 38. (Paris: J. Hermann, 1922.) 3 francs.

ELLIPTIC functions are not studied by mathematical students unless they are specialists in mathematical analysis, yet a knowledge of the most important elementary facts about these functions is essential for advanced work in many branches of pure and applied mathematics. Prof. Humbert's object is to supply this information in a conveniently brief form. Starting with the elementary theory of residues and contour integrals, the author introduces the notion of periodic functions defined by integrals: doubly periodic functions then follow, leading to the $\wp$ function and some of its most useful properties. We then get the ζ and σ functions, and finally modular functions are touched upon. The book forms a clearly written introduction which cannot but encourage the student to seek for further and more detailed information in standard treatises. S. B.

On the Edge of the Primeval Forest: Experiences and Observations of a Doctor in Equatorial Africa. By Prof. A. Schweitzer. Translated by Ch. Th. Campion. (London: A. and C. Black, Ltd., 1922.) *6s.* net.

THE author resigned his professorship in the University of Strasbourg in order to qualify in medicine with the view of working among the natives of the French Congo. His work is an account of five years' experience at Lambarene on the Ogowe River. Prof. Schweitzer is evidently a close observer, and he succeeds in giving a vivid picture of the monotony of life in the oppressive luxuriance of the tropical forest. The considerable attention devoted to medical and surgical matters does not lighten the gloom. There are a few interesting reflections on some urgent tropical problems, such as the labour question and the relation between blacks and whites, which, in view of the author's experience, might with advantages have been expanded. The book is a short one, but not without value as a contribution to the study of the negro and his relations with the trader and missionary.

Evolution of the Essex Rivers and of the Lower Thames. By Prof. J. W. Gregory. Pp. 68. (Colchester: Benham and Co., Ltd., 1922.) *2s. 6d.* net.

As this book's geological contents occupy not quite sixty pages, and as "Bibliography and References" occupy three pages, and refer to fifty-nine different memoirs, or papers, on various points in Essex geology, it is obvious that no brief view of its conclusions is possible here. The views expressed as to the "Evolution of the Essex Rivers" and "The Relations of Essex and Midland River Systems," etc., are not antagonistic to those of previous writers, but are mainly occupied by matters more or less outside those treated by Essex geologists of an earlier date. In short, it is a brief work of much value to all students of Essex geology. T. V. HOLMES.

Letters to the Editor.

Spectrum Lines of Neutral Helium.

DR. SILBERSTEIN'S letter in NATURE of August 19, p. 247, induces me to write to say that some time ago I found the key for unravelling the constitution of the secondary spectrum of hydrogen to be of a kind similar to, though more generalised than, that used by him for helium. Practically the whole of this spectrum depends on the sequence of the Balmer series. If $f(m)$ denote the mth sequent, the wave number of any line is of the form $\Sigma k_m f(m)$, where the k_m are positive or negative integers; *e.g.* the line $n = 16892.72$ is $f(2)-f(3)+f(4)-f(5)-f(6)+f(7) = H_\alpha + (H_\gamma - H_\beta) - (H_\delta - H_\epsilon)$ within an observation error $d\lambda = 0.01$. In fact the spectrum is a kind of linkage spectrum in which the usual links are replaced by the separations between the successive lines of the primary, namely, 5331.57, 2467.75, etc. The same machinery of analysis used for linkage spectra is then directly applicable, but as the total number of observed lines is about 1600 it may be understood that a considerable time is required for the completion, arrangement, and discussion of the various physical effects in different groups of lines. The preliminary work of forming the linkage maps is practically completed. The results so clearly suggested that Curtis's helium spectrum was built in the same way that I was on the point of writing to him to suggest his testing them, and now Dr. Silberstein's very interesting letter comes to show independently that this is the case.

It has always seemed to me that the existence of these linkage spectra forms a difficulty in the orbital theory of spectral lines. This difficulty Dr. Silberstein's theory does not meet. According to his theory, and apparently in any orbit theory, the two electrons are moving independently, and each passes between two of its corresponding paths. But if the combined change of energy is radiated, these two events must be absolutely simultaneous, and would happen, say, once in an æon.

W. M. HICKS.

August 19.

Micro Methods in the Practical Teaching of Chemistry.

A CHANGE in teaching methods which brings with it simplicity and economy should appeal to all. May I therefore direct attention to methods I have myself begun in Cairo of teaching chemistry from the beginning by "microchemical" methods—that is, by working with very small quantities? (We really need a better word than "microchemical," which seems to suggest the microscope.)

It is strange that even in science we are so conventional. Pieces of apparatus once introduced by some one of repute remain in the shape and form, size and weight in which they were first employed as if they were consecrated objects. The Bunsen burner, for example, although it may be far bigger than required and very expensive in its consumption of gas, is scarcely ever changed. Even where a far less consumption of gas would suffice it seems to be the tradition to burn a large quantity. It is the same with the size of the test tube, beaker, or flask in common use, and the same also with the quantity of material used by the student in carrying out his chemical tests; he will as a rule take a quarter, if not a half, test tubeful of some solution and add as much of the testing reagents as he can get into the test tube. There seems to be no necessity for these large quantities, and most of the tests carried out by students in chemical laboratories could be done with far less material. I propose to describe some of the methods which have been used in the Government Medical School Chemical Department, Cairo, during the past year, feeling that many laboratories would gain much in time, materials, and money by following methods which have proved very successful there.

These methods arose out of necessity. Too many students and too little space is probably a state of things not special to Cairo; the extreme was reached when it became necessary to teach two hundred students without any proper laboratory at all. Rather than refuse admission to the students a solution of the difficulty was sought in microchemical methods, and the result was successful beyond anticipation. Many who visited the laboratory at the time were surprised to see a hundred students seated in perfect silence busily engaged in applying microchemical methods in a hall in which there was neither water nor gas nor any of the appurtenances of a chemical laboratory. The necessity for such an improvisation could scarcely arise under more settled conditions, nor for that reason is it likely that any one would have the opportunity of carrying out such a teaching experiment on so large a scale.

The root idea of the method is economy in its broadest sense—in time, labour, and materials. Clearly if the student uses nothing larger than a drop instead of the habitual inch or half-inch in a test tube the expense in chemicals can be readily reduced one hundredfold. The expense in students' chemicals represented during the year only a few pounds of materials, the consumption of most of which is to be attributed to second-year students doing special work. About 500*l.* has been saved out of chemicals alone, which saving can be applied to the purchase of permanent apparatus.

The economy in apparatus has been even greater than in chemicals. The bottles throughout the laboratory have been reduced to one tenth of the conventional size. Each student is given at first a small rack, and later another, containing six reagent bottles of one ounce capacity. These bottles are unstoppered but fitted with small dropping-pipettes. The bottles are cheap and the pipettes are made in the laboratory. The racks are easily collected and stored, and it is possible in this way to keep a class constantly supplied with freshly prepared solutions by issuing only those reagents which it is intended to employ at the time, thus avoiding the making up at the beginning of term of large quantities of solutions which may not be required till many months later. No test tubes are used till the student comes to actual separation of the groups, so that for the first half of the course all the expense and annoyance of breakage, difficulties of cleaning, and mess due to test tube work on the benches is avoided.

Indiscriminate test-tubing by students untrained in delicate manipulation and without any quantitative sense is, as it seems to me, a bad influence in their training which it is important to combat. In so many schools has it been the custom to use materials in wastefully large quantities that the name "stinks" only too aptly describes what goes on. But if the student be taught from the outset to regard the drop as a suitable, if not already a large quantity, he will get nearer to the quantitative notion and may acquire some of that delicacy of manipulation so essential to

his proper training; and when he comes to use larger quantities of materials and more expensive apparatus he is more likely to do so with economy and care

In the early part of the work many simple substitutes for the test tube may be used, and there is an advantage in variety, the chief of many considerations being the ease with which such things are washed a glass slide, as used for the microscope, or any small piece of glass is suitable—for it may be rapidly cleaned after each drop-experiment—and the drop may be studied with the pocket lens, enabling the student to distinguish between crystalline and amorphous precipitates and to note whether the colour is in the precipitate or the solution, indeed the training of the student in the use of the pocket lens from the very outset is highly desirable Other materials are porcelain tiles or broken china, readily replaced by the student himself A third class of material, very convenient and possessing certain advantages in chemical tests, is filter-paper or some form of absorbent paper, or in its absence white paper of any kind When a reaction takes place in a drop on filter-paper, the separation of the precipitate from the solution becomes even more obvious than when the same reaction takes place on a tile or piece of glass. He may learn something also about surface tension, adsorption, and the difference between crystalloid and colloid, and many elementary physical facts which he would never learn by the test tube method.

There are very few reactions commonly carried out in the chemical laboratory which cannot be carried out just as well or better in the microchemical way, for example, the reduction of a copper solution by an aldehyde Let the student place several separate drops of Fehling's solution on a glass slide and to each add a drop of some different aldehyde solution, let him warm the slide gradually over a small flame and make comparison of the changes in the several drops This is an example of an experiment of a simple kind where an attempt is made to obtain constant conditions, varying only one factor. Such instructive little tests as these are surely worth far more than mere colour or precipitation tests in test tubes Many more such tests could be described, but each teacher will probably prefer to devise experiments of his own, suited to the needs of his class

It is submitted, therefore, that microchemical methods form not only an excellent introductory training for the student but mean a great saving in time, labour, and money We have saved in one year at least 1,000*l*, enabling us to buy more apparatus of a permanent kind for teaching and research

EGERTON C GREY

Government Medical School,
Cairo, July 1922.

An Atomic Model with Stationary Electrons.

BOHR'S atomic model with its circling electrons appears at first sight quite incompatible with Langmuir's model, in which the electrons are stationary or oscillate about fixed positions of equilibrium. Dr. Langmuir himself, however, has pointed out that a static atom possessing many of the properties of the Bohr atom is possible provided a force of repulsion equal to $F=1/mr^3 . (nh/2\pi)^2$ act between an electron (mass m, charge e) and a nucleus. Here n is an integer and h is Planck's constant. The distance r of the electron from the nucleus in stable equilibrium is the same as the radius of a circular orbit corresponding to a stationary state in Bohr's theory. The total energy of the electron is also the same as that given by Bohr's theory. The frequency of oscillation about the position of equilibrium is identical with the frequency of revolution of the electron in the Bohr atom. Thus the Rydberg constant and the Balmer series can be deduced without assuming moving electrons.

I wish to direct attention to the fact that a force of exactly the type required in Langmuir's theory is provided by the quantum mechanism recently described by Prof. E. T. Whittaker in the Proceedings of the Royal Society of Edinburgh. The mechanism may be pictured as a magnetic wheel consisting of a number of magnetic poles (total strength M) revolving in a circle of radius a. When this magnetic wheel is rotating about its axis with angular velocity ω, it sets up an electric field such that an electron situated at a point on the axis at a distance r, large in comparison with a, is acted on by a force $Mea^2\omega/r^3$ along the axis. Prof. Whittaker has shown that the angular momentum of the magnetic wheel in its steady state (after the passage of an electron completely through it) is determined by $A\omega=2eM$, where A is the moment of inertia of the wheel We shall assume that, in general, the angular momentum is given by Nicholson's quantum relation, so that

$$A\omega=2eM=nh/2\pi$$

Substituting the values of Me and ω thus found in the expression for the force on the electron, we find that the "quantum force" is given by

$$\frac{a^2}{2Ar^3}\left(\frac{nh}{2\pi}\right)^2.$$

This agrees precisely with Langmuir's expression for the force of repulsion, provided we make the single additional assumption that $A=\frac{1}{2}ma^2$.

Thus we see that by means of Prof Whittaker's quantum mechanism it is possible to construct an atomic model which will yield many of the results of Bohr's theory, without employing moving electrons. I have discussed the question more fully in a paper to be published by the Physical Society of London.

August 15.

The Variable Depth of Earthquake Foci.

PROF. H. H TURNER has given reasons (Mon Not R A S, Geophys. Suppt No 1) for believing that the depths of the foci of earthquakes differ among themselves by quantities up to about 300 km. It may be pointed out that this is precisely what may be expected from the theory of a cooling earth The available information concerning the thermal state of the earth indicates that the rocks in the asthenosphere, at depths of 400 km. and more, must be very much weaker than those at the surface; this is amply confirmed by the geodetic evidence collected by Barrell, which also suggests that the rocks at depths comparable with 100 km are considerably stronger than those at the surface Accordingly, whatever may be the cause of crustal deformation in the earth, yield will occur in the asthenosphere for smaller stresses than are necessary to produce it in the upper parts of the crust. Thus the earthquakes arising from fractures below 400 km. would be more numerous but much less violent than those occurring at higher levels, and the greatest earthquakes should have their foci at the depth of greatest strength. We should therefore expect that the depths of earthquake foci may range from zero to 200 or 300 km.

DOROTHY WRINCH.
HAROLD JEFFREYS.

August 21, 1922.

An Electrical Analogue of the Vocal Organs.

In connexion with correspondence which recently has appeared in the columns of NATURE relating to the physical characteristics of vowel-sounds, the following account may be of interest of an apparatus believed to be novel, which is conveniently capable of the artificial production of many speech-sounds. It is well known that Helmholtz succeeded in imitating vowels by combinations of tuning forks, and Miller by combinations of organ pipes. Others, notably Scripture, have constructed apparatus wherein the transient oscillations of air in resonant cavities were excited by series of puffs of air, in close physical imitation of the action of the human vocal organs. It seems hitherto to have been overlooked that a functional copy of the vocal organs can be devised which depends upon the production of audio-frequency oscillations in electrical circuits.

A schematic diagram of such an apparatus is given in Fig. 1. Periodic interruptions of the electric current, produced by a buzzer or a motor-driven circuit interrupter, corresponded to the periodic interruptions of the air current in the human throat by the vocal cords. The intermittent electric current thus produced excited the natural damped oscillations of the resonant circuits, *1* and *2*. This was confirmed by observation with an oscillograph. In like manner, puffs of air from the vocal cords excite the natural damped oscillations of the air in the mouth cavities. The work of numerous investigators has indicated that the air in the mouth cavities possesses, as a rule, only one or two important modes of vibration. The oscillations of the electric current were transformed to sound-vibrations in the air by a loosely coupled telephone receiver. The distortion introduced by this telephone receiver appeared to be of little importance.

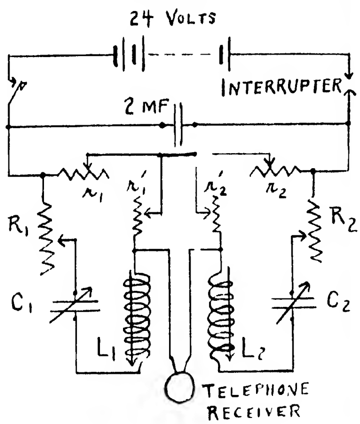

FIG. 1.

Appropriate adjustments of the resonant circuits *1* and *2* were observed to result in the production of all the various vowels and semi-vowels in turn. Alteration of the frequency or damping of either resonant circuit was observed to result in alteration of the vowel produced. The frequency of interruption, which was the group frequency of the recurrent damped oscillations, was observed to determine the pitch of the vowel; but it did not determine what vowel was produced. Similarly, in the case of the human voice the frequency of vibration of the vocal cords is known to determine the voice-pitch, while the adjustment of the mouth cavities is known to characterise the vowel.

The vowels and semi-vowels produced by the "electrical voice" with regular interruptions, in the manner just described, were equivalent to intoned or sung vowels, or, if the frequency of interruption was made to vary appropriately, to spoken vowels. It was found possible to produce the whispered vowels with interruptions that were non-periodic, which is in accordance with the idea that, in the human voice, whispered speech is due to irregular frictional modulation of the exhaled air. Whether the vowel was whispered, sung, or spoken depended upon the manner of making the interruptions, while what particular vowel was produced depended upon the adjustment of the resonant circuits.

Diphthongs were produced by altering the circuit adjustments rapidly so as to shift from the initial to the final vowel-sound of the diphthong pair. Some of the fricative (hissing) consonants were approximated with irregular interruptions, provided the resonant circuits were set at somewhat higher frequencies than for the vowels and semi-vowels. None of the explosive consonants were satisfactorily imitated. It is believed that lack of success with the explosives was due to obvious difficulties of manipulation.

There was much room for improvement with respect to the naturalness of the "electrical voice." It was too monotonous, as was to have been anticipated. Contrary to expectation, alteration in the wave-form of the exciting current did not materially change the tone, provided the wave-form was sufficiently far from sinusoidal. The intoned vowels, semi-vowels, and diphthongs produced by the "electrical voice" were sufficiently natural to be recognised in at least fifty per cent. of the trials by eight or ten different observers. When arrangements, not indicated in Fig. 1, were made to give the appropriate circuit adjustments in rapid succession, simple words like "mama," "Anna," "wow-wow," "yi-yi," were fairly well imitated. The whispered vowels and fricative consonants were not imitated so well, because (it is thought) of the lack of complete irregularity in the circuit interruptions. In human speech the pitch and vowel quality and intensity are constantly changing in a way difficult to imitate with the crude apparatus of Fig. 1. Probably, also, in the human voice additional weak transient oscillations are excited, due to minor modes of vibration of the air in the cavities of the head, which determine the individuality of the voice without greatly altering the speech-sounds.

Thus these experimental results are sufficient to give a general qualitative description of each of the following four classes of speech-sounds: vowels, semi-vowels, diphthongs, and fricative consonants (but not explosives), whether sung, spoken, or whispered; and these results also make possible quantitative specification of the characteristics of the various speech-sounds themselves. Numerical values of the frequencies and dampings which appear to characterise the various speech-sounds have been calculated from the electrical constants possessed by the resonant circuits of the apparatus when adjusted to produce them.

The analytical expression for a single transient due to one resonant circuit when loosely coupled is, of course,

$$\text{Instantaneous displacement} = Ae^{-at} \sin 2\pi ft,$$

where e is the base of natural logarithms, a the damping constant, f the frequency, and A the amplitude. The displacement in the air-vibration is taken as proportional to the instantaneous current. Also, $f = 1/2\pi\sqrt{LC}$ nearly, and $a = R/2L$. The capacity C

of each resonant circuit was variable in steps from 0·001 to 2 microfarads. The inductance L was continuously variable from about 0·3 to 0·7 henry. The resistance R was due largely to a dial box of range 1 to several thousand ohms, and included, in addition, the resistance of the inductometer and the (perhaps 100 ohms) small variable coupling resistances r and r' (Fig. 1).

The nature of the numerical results is indicated in Table I., which gives approximate values of the frequencies and dampings of the recurrent oscillations which characterise six of the more important vowels. Group frequencies (that is, voice pitches) were for each vowel varied over the range 75-300 per second. The first three vowels given in this table are each characterised by a single train of recurrent damped oscillations; the remaining three are characterised by two trains of recurrent damped oscillations. The numerical values are approximate. Indeed, considerable changes in the circuit adjustments in some cases do not materially alter the vowel produced. The problem of determining the permissible range of variation for each speech-sound requires further study. For the latter three vowels the relative values of r_1 and r_2 are of some importance.

TABLE I.

Vowel	Damping Oscillations: Frequency, f	Damping constant, a (Unit of Time, one second.)
rude	320	small (< 50)
law	650	100
father	1000	500
mat	{ 750 { 1500	800 } 800 }
pet	{ 420 { 2300	50 } 50 }
code	{ 320 { 2500	50 } 50 }

These results seem sufficiently interesting to recommend the apparatus of Fig. 1 to the attention of students of speech-sounds. Although simple in construction, this apparatus possesses considerable flexibility and range. The really difficult problem involved in the artificial production of speech-sounds is not the making of a device which shall produce sounds which, in their fundamental physical basis, resemble those of speech, but in the manipulation of the apparatus to imitate the manifold variations in tone which are so important in securing naturalness.

As for the disagreement between the Helmholtz-Miller, or steady state theory of vowels, and the Willis-Hermann-Scripture, or transient, theory, Rayleigh pointed out that the conflict was only apparent. The disagreement concerns methods rather than facts. Which view-point should be adopted is thus a matter of convenience in a given case. When the transmission of speech over telephone circuits is in question, for example, the steady state theory often possesses obvious mathematical advantages. On the other hand, the quantitative data relating to the physical nature of vowels which are given in Prof. Miller's well-known book, "The Science of Musical Sounds," expressed, as they are, in terms of the steady state theory, are less compact and definite than the data of Table I., which are expressed in terms of the transient theory. The general agreement between the two sets of data is, of course, obvious.

The work described in this communication was performed while the writer was associated with the American Telephone and Telegraph Company, and was carried out in the laboratories of that company and of the Western Electric Company, Inc.

Interspecific Sterility.

DR. GATES, in his letter which appears in NATURE for August 5, p. 179, emphasises the importance of tetraploid species in evolution, and with this position I heartily agree. Nevertheless, I do not think that the difficulties in the way of free crossings amongst diploid, tetraploid, and hexaploid species are so great as seems at first sight probable, at any rate in the Salicaceae.

In this order Miss Kathleen B. Blackburn and myself have been conducting cytological researches for some time, and find the fundamental chromosome number, both in Populus and Salix, to be nineteen. Up to the present only diploid species have been encountered in the first-named genus, but in Salix, on the contrary, diploid, tetraploid, and hexaploid forms have revealed themselves. In this communication I wish more particularly to direct attention to that homogeneous assemblage known as the Capreae group, which includes, in the eyes of most salicologists, three genuine species, *Salix caprea*, *S. cinerea*, and *S. aurita*—an arrangement entirely in harmony with my own views. Still, so closely related are these three plants that many botanists, both British and continental, have refused to see in them more than one polymorphic species; similarly, others, although they admit the distinctness of *S. aurita*, combine *S. cinerea* with *S. caprea*. Despite this, *S. aurita* and *S. cinerea* manifest themselves cytologically as purely tetraploid species, while *S. caprea*, in the main a diploid form, possesses a tetraploid race indistinguishable in the field from the commoner and normal diploid type. Furthermore, what is especially noteworthy, any one of these four forms can be crossed readily with the other three, and the F_1 hybrids thus obtained prove perfectly fertile *inter se*. Not only is this the case, but, in addition, other species can be brought into the chain, as, for instance, in the complex cross [(*Salix purpurea* × *S. viminalis*) × *S. cinerea*] × *S. caprea* (tetraploid), produced in my garden, and in the still more complicated hybrid {[(*S. cinerea* × *S. purpurea*) × *S. aurita*] × (*S. viminalis* × *S. caprea*)} × (*S. viminalis* × *S. phylicifolia*), secured by Heribert-Nilsson: in the former, two diploid and two tetraploid species have taken part, and in the latter, three (or two) diploid, two (or three) tetraploid, and one hexaploid form.

As a matter of fact, in the genus Salix, interspecific sterility depends, not on the chromosome complement of the species concerned, but on the physiological divergence of the groups to which they happen to belong. Experiments designed to cross the diploid *S. triandra* with the diploid *S. purpurea* turn out just as fruitless as similar attempts to hybridise it with the tetraploid *S. cinerea* and the hexaploid *S. Andersoniana*; on the other hand, the hybrid combinations between it and the tetraploid *S. alba* and *S. fragilis* can be obtained with the utmost ease.

The Mass-spectrum of Iron.

I HAVE recently investigated this element by using the vapour of its penta-carbonyl mixed with carbon dioxide. It is even more troublesome to deal with than the corresponding nickel compound, but by employing intense discharges and long exposures fairly satisfactory results have been obtained.

The mass-spectrum of iron is characterised by a strong line, approximately at 56, and it may be con-

cluded with absolute certainty that this line is due to the predominant constituent of the element. Refined measurements indicate a value rather less than this integer. The mean of some sixteen independent and very consistent comparisons with lines due to mercury and compounds of carbon and oxygen works out at $55 \cdot 94 \pm 0 \cdot 05$.

The accepted chemical mean weight, 55·84, suggests the presence of a lighter isotope, and a general consideration of elements already analysed points to the value 54 as the most probable. A very faint line is, indeed, visible in all cases where the 56 line is really strong, but it is impossible to make certain that it is due to iron Further, if we accept the difference of the above figures as exact and assume 54 to be the only lighter constituent, this line should have about one-twentieth the intensity of the 56 line; actually its intensity appears much less.

Iron may therefore be taken as being almost, if not entirely, a simple element of atomic weight, approximately 56 It may contain a small proportion of an isotope 54, but this is by no means certain F. W. ASTON.

Density of Adsorbed Films.

WHEN a very small quantity of such a liquid as castor oil is placed upon a clean surface of water dusted with talc, it spreads over the water surface, brushing the talc on one side, and forms an invisible circular spot, the size of which depends upon the amount of oil used This adsorbed film has the same surface tension as the surrounding water surface, namely, 73 dynes per cm Hence Devaux, Langmuir, and others regard the film as being only one molecule thick

If such an invisible film of castor oil be contracted, the surface tension decreases until it falls to about 57 2 dynes per sq cm Further contraction does not much reduce the tension. Marcelin was of opinion that as the diameter of the film was decreased, it thickened until it was two molecules thick, and that when this occurred, the film had the same surface tension as castor oil in bulk But the amount of contraction the surface undergoes in the case of castor oil is only about 40 per cent, and this Devaux points out is not sufficient to make the film two molecules thick, and he suggests that these thicker films are not two molecules thick, but are monomolecular films with *closer packing* of the molecules On this view the film of limited area surrounded by water is stretched until its tension reaches that of a clean surface of water

If the above explanation be correct, it is clear that the density of the stretched film of oil having a surface tension of 73 dynes per cm must be considerably less than that of the same film when its surface tension is only 57 2 dynes per cm

Now when calculating the dimensions of the molecules of various substances, by the surface tension method, I gather that Devaux and Langmuir regard the oil films, when they are stretched by the surrounding water surface, as having the same density as the liquid in bulk Would it not be safer to assume that the density of the film, when it has the same surface tension as the oil in bulk, is more nearly equal to that of the oil in bulk? The point is one of considerable interest and importance, and well worthy of consideration.

The Pigeon Tick.

WE wish to record the occurrence of the pigeon tick, *Argas reflexus*, in Cambridge, where it is parasitic on the pigeons which breed between the inner and outer roofs of King's College Chapel On August 4 we found a specimen, which Mr. C. Warburton was kind enough to identify for us. This specimen is now in the collection of the Molteno Institute of Parasitology. On a later date we found six more individuals.

The parasite seems to have been found previously in the British Isles in Canterbury Cathedral only, and not at all since 1908. This new locality, therefore, may indicate that it will be found elsewhere if searched for carefully.

The adult tick is not permanently attached to its host, but hides in crevices in masonry and woodwork, leaving its hiding-places to feed at night

Zoological Laboratory, Cambridge.

An Ancient Wasp.

I HAVE just received from Mr. John P. Byram a small collection of fossil insects which he obtained at the head of Bear Gulch, 12 miles from Una, Colorado. The formation is Green River Eocene, and Mr. Byram states that the material comes from a lower stratum than the insects previously obtained by us. One of the specimens is a beautifully preserved wasp, with wings outspread, belonging to the modern genus Hoplisus. It is 12 mm. long, with a wing-spread of about 19 mm.; the head and thorax are black; abdomen fusiform with narrow base, and the hind margins of the segments broadly pale-banded, as in living species; the legs are colourless, probably yellow originally; the anterior wing shows a pallid stigma, and a strong dusky cloud including the basal part of the marginal cell and the whole of the second submarginal; the venation is essentially that of the modern *Hoplisus quadrifasciatus*, except that the marginal cell is more slender, and in the hind wing the cubitus practically meets the nervulus

The only fossorial wasp from the Eocene previously described is Scudder's *Didineis solidescens*, which is evidently quite different from the present species, but is too poorly preserved for the accurate determination of the genus No older wasps are known.

This Eocene Hoplisus, which may be called *Hoplisus archoryctes*, doubtless preyed on the Homoptera, which are so numerous in the same rocks. It is, I think, the most impressive instance of the persistence of type which I have ever seen, when we consider that it belongs to a highly specialised group of insects, and proves that within this group there has, at least in one line, been no change of form or colour in the many millions of years which we now believe to have elapsed since the Eocene Even the cloud on the wings is as in living species Could the species be restored to life, *H. archoryctes* would fall into our system, merely forming another species to be added to the many similar ones existing.

The Zoological Society.

By E. G. BOULENGER.

BEFORE the foundation of the Zoological Society of London in 1826 there was no organisation in this country devoted solely to zoological science. The Royal Society, as it still does, occasionally published papers of zoological interest, while the Linnean Society, which undertook the discussion of both zoological and botanical subjects, at this time rated the latter science of more importance than the former. As to the exhibition of living animals, during the first quarter of the nineteenth century the only collections in the country were those of the Royal Menageries at Windsor and at the Tower, and the private one of Mr. Cross at Exeter 'Change in the Strand. Hence it came about that a band of enthusiastic zoologists headed by Sir Stamford Raffles, who had just returned from administrative duties in the East Indies, decided on founding a Zoological Society in London. At the first general meeting, held in the rooms of the Horticultural Society in Regent Street, which was attended by more than a hundred persons, Sir Stamford Raffles was elected president. Unfortunately the president and founder died a few months later—some years before the society acquired its charter of incorporation, granted in 1829, in which the Marquis of Lansdowne is named as the first president of the chartered society, and Mr. N. A. Vigors the first secretary.

Twenty acres of ground in Regent's Park having been obtained from the Government at a nominal rent, the gardens were laid out in accordance with the plans of Decimus Burton, and opened in 1828 with a stock consisting of 152 mammals and 475 birds. The first animals to come into the possession of the society were housed at the offices in Bruton Street, where they were kept until suitable accommodation had been provided for them in the gardens. The first animal to be received was a griffon vulture, which lived in the menagerie for forty years. While the menagerie was being formed in Regent's Park the society was engaged in establishing a museum of preserved specimens in Bruton Street. The museum attracted so many donations, becoming in consequence so crowded, that in 1836 more commodious quarters were taken for it in Leicester Square. In 1843 the collections were transferred to the gardens, and housed in a building on a site now occupied by the society's offices. Indeed, in the early days of the society the museum was regarded as the centre of the society's usefulness. When, however, the zoological department of the British Museum developed, the absurdity of endeavouring to maintain an inferior collection in the same city became apparent, and in 1856 it was decided to part with the collection and present the type specimens to the national museum.

The establishment of a farm at Kingston was another of the society's early enterprises. Its object was to give accommodation to animals requiring a greater range and more quiet than the gardens in Regent's Park could afford. It was also considered necessary for the purpose of breeding and rearing young animals, and especially for attempting to naturalise such species as were hitherto unknown in this country. This experiment was a costly failure, and was abandoned in 1836.

In the infancy of the society there were no scientific meetings, communications on subjects of zoological interest being submitted at the general meetings. In 1829 a special committee of science and correspondence was formed, at the meetings of which zoological subjects were discussed. The committee met until 1832, when an alteration was made in the by-laws by which the committee meetings were replaced by general meetings for the discussion of scientific business. These were held first at Bruton Street, but in 1843 the society moved to No. 11 Hanover Square, where it remained for forty years. In 1884 more commodious premises at No. 3 of the same square were acquired, and the meetings were held there until 1909, when the society moved to its present premises in the gardens.

The principal features of the gardens at its opening consisted of a lodge on approximately the site of the present main entrance, where visitors provided with a fellow's order paid a shilling for admission; a bear pit which still existed fifteen years ago on the site of the terrace, built in 1843; a yard for kangaroos on the site of the present eland paddock; sheds for deer and goats, and dens for large "quadrupeds"—tenanted by a lion, a tigress, a pair of leopards, a puma, a hyæna and a pair of polar bears on the site of the Lion House; a Monkey House with poles outside to which the monkeys were fastened during the summer months, on the site of the recently demolished otter pond; an enclosure for emus where the pelican enclosure now stands; paddocks for cranes and other large birds on the site of the present Eastern Aviary; an aviary for small birds, renamed the Crescent Aviary, which was demolished only last year, on the site of the new tea pavilion; and a Llama House with clock tower, the present Camel House, which alone of all the original houses and enclosures stands where it did in 1828. Just north of the Llama House was a yard with cages which housed a hybrid between a jackal and a dog, some bears, dingos, and a sable. On the site of the present Llama House were cattle-sheds containing an American bison. Towards the close of the year 1829 the tunnel connecting the south and the middle gardens (then called north garden, the present north garden being acquired at a much later date) was built, and a repository was constructed on the site of the present offices. The repository served for the reception of the animals on their arrival, and in turn has been converted into a reptile house, a museum, a small cats' house, and a squirrel house.

The gardens soon acquired great popularity, the annual admissions between the years 1830 and 1840 averaging more than 200,000. From the year 1840 the income of the society gradually decreased until in the year 1847 there were only 88,500 visitors. In that year Mr. D. W. Mitchell was appointed the first paid secretary, and with the general change of policy which he introduced matters immediately improved. To Mr. Mitchell, who held office till 1859, when he took up

the directorship of the Jardin d'Acclimatation, then just founded in Paris, were due the abolition of the rule which required that all visitors should be provided with a fellow's order, and the policy of admitting the public on Mondays, and children at any time for sixpence each. On Mr. Mitchell's retirement, Dr. Philip Lutley Sclater was elected to the post of secretary, which he held until 1901. During the lengthy period that he held office many changes were effected in the gardens, the most important being the erection of the Antelope House (1861), the Eastern Aviary (1862), the Monkey House (1864), the Elephant House (1868), the Lion House (1876), the old Insect House (now the Rodent House) (1881), the Reptile House (1887), the Ostrich House (1897), the Llama House (1898), the Zebra House (1899), and the Ape House (1901), all of which are still standing and are to be distinguished on the accompanying aero-photograph. Towards the end of the year 1901 Dr. Sclater retired after serving the society for forty-three years, a period during which the society occupied a very high position in the scientific world. On his retirement his son, Mr. W. L. Sclater, held the office of secretary for a short period, but at the following annual meeting, on a vote of the fellows, the present secretary, Dr. P. Chalmers Mitchell, was elected to the post. Just prior to the retirement of Dr. Sclater some dissatisfaction had been expressed by a number of fellows with the housing conditions in the gardens, and the new secretary was soon at work, carrying out various improvements which gave immediate satisfaction to the fellows and public.

Apart from realising the necessity of doing away with various small cages, and giving their inmates more exercise, Dr. Chalmers Mitchell, in spite of some opposition, insisted that many of the animals, which hitherto had been confined all the year round in very hot cages, should be given access to the open air. It was then the general belief that most of the creatures coming from the tropics should be kept very warm, and consequently their housing conditions were determined almost solely by considerations of temperature. Now visitors to the gardens in winter may see a host of tropical animals in the open, a change of policy which has had the effect of improving greatly the

general health of the exhibits. The secretary also realised that in the past, when new buildings and enclosures were erected, in most cases immediate convenience took precedence of any general scheme. In 1909 he induced the council to consider the condition of the gardens with regard to existing buildings of a permanent character, and recommended that in the future, as buildings and enclosures were erected, they should be arranged in conformity with a general plan. The matter was temporarily shelved, but in 1912 the garden committee drew up a list of the animals the society could expect to exhibit under suitable conditions at any time, considered the existing accommodation, deciding how far it was to be regarded as satisfactory, and what areas should be reserved for the supply of further accommodation as it could be provided. It is in conformity with the plan then drawn up that the various buildings and open spaces provided in recent years have been erected and set out.

In 1906 and in 1907 the society obtained additional grants of land from H.M. Commissioner of Works. The 20 acres of land granted to the society in 1826 lay on both sides of the Outer Circle, corresponding roughly with the existing middle and south gardens, but only a portion to the south of the circle was laid out. In 1834 an additional plot of ten acres on the south-west border of the gardens was obtained at an annual rental, on the condition that it was to be used as pasturage. In 1839, use of the land north of the Regent's Park Canal, corresponding to the existing north gardens, was granted.

In 1841 the ground in the occupation of the society was rearranged. The strip on the north bank of the canal was surrendered, and a portion at the east end of the middle garden was exchanged for a corresponding area at the west end, and permission was given to extend the works over the ten acres granted in 1834. In 1869 the land on the north bank of the canal was again taken over by the society. A considerable portion of the north garden was, however, not made use of until after 1903, when the policy of increasing open-air facilities for the animals was put into operation. Complete use of the north garden was, however, not possible until 1906, when the right-of-way was obtained over two unoccupied portions of ground on both sides of the canal, and H.M. Commissioner of Works agreed to allow half of the new bridge over the canal to be used by the society on payment of its proportion of the cost of reconstruction. A communication between the north and the middle gardens was thus obtained. In 1907 a strip of ground was obtained along the south-west boundary of the south garden, which ends in a large triangular area at the west end, now occupied by a pond for water-fowl, and goose paddocks. The condition attached to the grant of the new piece of land was that the animals placed on it should be visible to the public in Regent's Park. The paddocks erected on this site now contain deer, llamas, emus, and rheas.

Of the buildings erected and designed under supervision of the present secretary, the Small Cats' House (1903), the Sea-Lions' Pond (1905), the Small Birds' House (1905), the Cattle and Deer Sheds (1906), the Society's New Offices and Library (1909), the Sanatorium (1909), the New Prosectorium (1909), the Mappin Terraces for the open-air display of mountain goats and bears, with its tea-pavilion (1913), the Small Mammal and Caird Insect House (1913), and the New Tea Pavilion facing the broad walk (1922), are the most important. The transfer of the offices, library, and meeting room to the gardens, apart from providing adequate accommodation for the library, which had outgrown the rooms in Hanover Square, has greatly facilitated the work of the staff. At the time there was some opposition to the transfer, a few fellows being of opinion that there would be a falling off in the attendances at the scientific meetings. Such, however, has not been the case, as at the present day they are attended far better than in the past.

How all the great improvements which have gradually been effected during the past twenty years have popularised the gardens may be best realised when we consider that the admissions, which in 1902 amounted to less than 700,000, last year exceeded 1,500,000. When the new fresh-water and marine aquarium, which the council has decided to build under the Mappin Terraces, is completed, the latter figure will no doubt be exceeded.

The Resonance Theory of Audition.

By Prof. E. H. BARTON, F.R.S.

THE resonance theory of audition continues to excite considerable interest and must be regarded as being still in the controversial stage. The very name is somewhat unfortunate and may have led some into the mistaken view that some sympathetic vibrators in the ear are postulated as capable of actual resonance or resounding like a tuning-fork set in audible vibration by another which was first sounded. Of course it should be understood, on the resonance theory, that the vibrator in question merely vibrates when a sound of nearly its own proper pitch is received by the ear, such vibration, though effecting audition by its possessor, being quite inaudible to others. Some through misunderstandings on this or other points have failed to grasp the essentials of the resonance theory of audition, and have in consequence levelled at it criticisms which clearer knowledge on their part would have obviated. No attempt will be made here to locate in the ear those mechanisms, if any, which play the part of sympathetic vibrators, responders, or resonators. That is left to the anatomists to discover. But we may note briefly the essentials of the resonance theory, the salient facts of audition and what power the theory has of meeting the demand which those facts make upon it. In the latter we may derive help from the consideration of a simple working model which any one may set up and experiment with for himself.

Essentials of the Resonance Theory.—This theory postulates the existence within the ear of some set of mechanisms, each of which has its own proper rate of vibration and rate of dying away when

left to itself. Each such vibrator can accordingly be set in vigorous vibration by very feeble forces, provided they occur at or very nearly at the rate in question. These sympathetic vibrations would quickly die away when their stimulating cause ceased. Each such vibrator is supposed to have nervous connexion with the brain so that the fact and amplitude of its vibrations may be transmitted thence and duly noted.

The theory is not primarily concerned with the exact nature or details of structure of these vibrators provided only that they fulfil the foregoing conditions for mathematical theory shows that the response of one such vibrator to the forces exerted upon it by another vibration obeys the same general laws quite independently of the details and nature of the vibratory responder under consideration.

Facts of Audition.—For normal ears the following may be regarded as the chief facts of audition with which we are here concerned :

(i.) The range of audition is limited at the upper and lower ends, such limit varying with individuals, but about eleven octaves are usually audible.

(ii.) Before either limit of audition is reached the notes may be recognised to be very high or low, but the distinct location of pitch fails, so that only about seven octaves are musically available.

(iii.) At about the middle of the range the discrimination of pitch between near notes when sounded successively is, for a keen ear, about the twentieth of an equal-tempered semitone or $\frac{1}{240}$th of an octave.

(iv.) When two very near notes of almost equal intensities are sounded simultaneously, the difference of their frequencies may be recognised by any one as the number of beats per second. This may serve to discriminate a pitch-difference of the fortieth of a semitone or half that just named.

(v.) When two different notes at a considerable interval (say C and G) are sounded together, both notes can be heard and their interval estimated, they are not mistaken for a single note of intermediate pitch (E or E♭). (This deserves special notice as being the direct opposite of colour vision for some parts of the spectrum, and will be dealt with in another article.)

(vi.) When several simple vibrations occur simultaneously, being produced in association from the same vibrating source, string or wind, the resulting character of the compound tone or note is recognised and spoken of as its quality, quality of tone, or tone simply.

(vii.) A musical shake of about ten notes per second on a note of frequency about a hundred and ten per second can be heard distinctly.

Power of Theory to meet the Facts.—Having briefly reviewed the chief facts of audition we may now naturally ask what power the resonance theory has to meet the demands thus made upon it. In other words, can the physicist imagine a set of vibratory responders the behaviour of which under vibratory stimuli would give results which correspond to those of human audition ? In trying to arrive at a right or possible solution, obviously many variables are at our disposal. They may be stated thus :

(*a*) The total range of pitches of the set of responders.
(*b*) The musical intervals between adjacent responders.
(*c*) The damping (or rate of dying away) of the vibrations natural to these responders when started and then left to themselves.
(*d*) The constancy or otherwise of the intervals and of the dampings throughout the range.
(*e*) The fineness of discrimination of relative amplitudes of vibrations of adjacent or other responders by means of the nerves attached to them.

These variables are more than are needed to make a solution possible; they leave a choice between a variety of possibilities which may be imagined by the physicist and suggested to the anatomist for examination and rejection or acceptance. Thus, for example, the less the damping natural to a set of responders the easier is the location of pitch by them. But the presence of objectionable damping could be balanced by an enhanced fineness in the nervous discrimination of relative amplitudes of adjacent responders. A word or two of explanation may be desirable as to the relation between the damping natural to a vibratory responder and the nature of its responses to various alternating forces of nearly its own frequency. Without entering here into the niceties of the mathematical theory it may be said broadly that the best response follows only with the best tuning between the frequency natural to a responder and that of the forces acting upon it. But the actual value of this response and its falling off consequent upon mistuning both depend on the damping natural to the responder. If the damping is very slight, then the response is very vigorous for precise tuning, but for quite small mistunings the response is almost negligible. This is often summed up by saying that for slightly damped responders the resonance is *sharp*. On the other hand, for highly damped responders the response is not so good for best tuning as in the former case, but this response is only slightly impaired by moderate mistuning of the forces. In other words, for strongly damped responders the resonance is *spread*.

Bearing these facts in mind we have to make a choice among the possibilities open to us so as best to meet the facts of the case. The facts (iii.) and (v.) show that the damping must not be too large, because that would involve spread resonance instead of the sharpness needed for the actual fineness of location of pitch experienced. On the other hand, fact (vii.) shows that the damping must not be too small, as in that case the sound heard from one note of the shake would run into that of the next and give a blurred effect contrary to experience. We have thus found limits between which the damping should lie.

In view of these considerations we may submit the following suggestions. Let it be supposed that in the ear there is a set of vibratory responders which—

1. Cover a range of seven or more octaves,
2. Are about twelve to the octave in the middle of the range and have a suitable damping,
3. Are in total number about a hundred.

Simple Model and its Behaviour.—To test the adequacy of the arrangement just postulated let the following simple model be set up as shown in the diagram, Fig. 1.

This responsive model consists essentially of a stout cord stretched across a room between the fixed
